FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented the report on the accounts of the Society, from which it appeared that the current cash-balance in the hands of the bankers was £454. He laid on the table the usual quarterly statement for the information of the members, and reported that the authorities of Chester had transmitted Exchequer Bonds to the amount of £1,800 (payable on the 8th May next), as their contribution towards the expenses of the Chester Meeting in July next. The Council ordered, agreeably with the recommendation of the committee, that a circular letter should be addressed to such members of the Society as were in arrear of their subscription.

EDITORSHIP OF JOURNAL.—Mr. Thompson, Chairman of the Journal Committee, presented the following report, which was adopted by the Council:

1. That the Council be recommended to appoint a paid Editor, but that the Journal be published, as hitherto, under the general superintendence of the Journal Committee.
2. That the Journal Committee, or such other Committee as the Council may appoint, be requested to make such inquiry as shall enable them to report to the next monthly Council the name of some competent person or persons to undertake the duties of Editor; and also to report the amount of salary which they think adequate to the requirements of the office.

On the motion of the Right Hon. the Speaker, seconded by Mr. Jonas, the very cordial and grateful thanks of the Council were voted to Mr. Thompson, Mr. Dyke Acland, and Mr. Wren Hoskyns, for the manner in which they had performed the laborious and responsible office of Joint-Editors of the Journal.

CONSULTING CHEMIST.—Sir John V. B. Johnstone, Bart., M.P., Chairman of the Special Chemical Committee appointed at the previous Council, presented the following report, which was also adopted.

1. That the fixed salary of £300 per annum hitherto given to Professor Way be given without alteration to the person who shall be selected to fill the vacant post of Consulting Chemist to the Society, for which he will be expected to make analyses for members, on terms approved by the Chemical Committee; to give three lectures annually, if called upon so to do; and to attend the meetings of the Council whenever required. Also, that £200 per annum, allotted to specific subjects of investigation, be, as heretofore, offered in the first instance to the Consulting Chemist.
2. That Dr. Augustus Voelcker, Professor of Chemistry to the Royal Agricultural College at Cirencester, be recommended, to fill the vacant post of Consulting Chemist to the Royal Agricultural Society of England.

CHESTER MEETING.—Lord Portman, Chairman of

the General Chester Committee, made reports, and entered into detailed statements connected with the arrangements of the Society's ensuing Chester meeting, to be held in the week commencing Monday, the 19th of July next. Those details had reference chiefly to the requisite inquiries to be instituted, and reports to be made to the Monthly Council in March by the General Committee, in conference with the Local Committee, on the accommodation afforded at Chester for a dinner of the Society, and on the plan to be adopted for the show-yard subsequently to the personal inspection and report of Mr. Manning. The Council adopted the recommendation of the committee, founded on Mr. Brandreth Gibbs's report, on the purchase of wheat and barley in the straw, for the trials of machinery, and the selection of land for the trial of the steam-cultivators. They also ordered that a clause should be introduced into the Prize-sheets, stating that all certificates received after the 1st May for implements, &c., and the 1st June for live stock, should not be accepted, but returned to their respective senders. The Secretary reported that the principal Railway Companies had signified their willingness to grant the same concessions in favour of the Society's Exhibition at the Chester Meeting, as on the occasion of former country meetings.

POULTRY-SHOW.—On the motion of Lord Portman, seconded by Mr. George Turner, the resolution was passed (of which Mr. Milward had given notice), that there should be no Show of Poultry at the Country Meetings of the Society after the current year.

MEMBER OF COUNCIL.—On the motion of Mr. George Turner, seconded by Mr. Dyke Acland, Colonel the Hon. Alexander Nelson Hood, of Cumberland Lodge, Windsor, was elected one of the General Members of Council, to supply the vacancy created by the transfer of Viscount Eversley to the class of Vice-President.

STANDING COMMITTEES.—The standing committees for the year were appointed.

FRENCH SHOW OF HORSES AND CATTLE.—The Earl of Clarendon transmitted to the Council a copy of the note addressed to him by the French Ambassador, enclosing copies of a notice issued by the Emperor of the French, having reference to an intended meeting to be held at Alençon from the 17th to the 20th of May next, for the exhibition of horses and cattle, with the view to the improvement of their several breeds. This show will be confined to animals bred in the district, and the property, for three months previously, of the exhibitors.

CARD OF MEETINGS.—Mr. Frere transmitted a form of card of meetings, which he suggested should be annually forwarded to every governor and member of the Society not in arrear of subscription.

WEEKLY MEETINGS.—Mr. Morton transmitted, on the part of the proprietors of the *Gardeners' Chronicle*, an application for reporters to attend the weekly meetings.

The consideration of these two communications was postponed.

The Council adjourned to the 10th inst.

A weekly Council was held on Wednesday, 10th of February: present, Colonel Challoner, trustee, in the chair; Hon. Colonel Hood, Mr. Alcock, M.P., Mr. Raymond Barker, Mr. H. B. Raymond Barker, Dr. Camps, Mr. Dent, M.P., Mr. Gray, Mr. Fisher Hobbs, Mr. Tull, and Professor Way.

Communications were received—1. From Professor Hartstein, of Bonn, enquiring the present state of public opinion in England respecting the application of liquid manure; 2. From Dr. Lyon Playfair, asking for information on the subject of wool; 3. From the Minister of Agriculture of France, a collection, on the part of the Government, of agricultural works published in his department since the former collection presented to the Society three years ago; 4. An application from the Mexican Company for a collection of seeds, which the Council referred to Messrs. Thomas Gibbs & Co., the seedsmen to the Society; 5. From Mr. Bandel, of Baltimore, specimens of his Wyandotte Prolific Indian Corn, grown from seed obtained from the Wyandotte Indians in 1853; with a specimen of the stem raised from a single grain.—Mr. Alcock, M.P., called the attention of the Council to the advantages which he thought Mr. Halkett's system of land-cultivation might probably be found to possess on further inquiry and experience of its capabilities.

The Council adjourned over Ash-Wednesday to the 24th of February.

BATH AND WEST OF ENGLAND SOCIETY

FOR THE ENCOURAGEMENT OF AGRICULTURE, THE ARTS, MANUFACTURES, AND COMMERCE.

A numerously-attended meeting of the Council of this Society was held at Waghorn's Railway Hotel, Taunton, on Saturday last, the Right Hon. Lord Courtenay in the chair.

THE CARDIFF MEETING, 1858.—Mr. JOHN WIDDICOMBE, the Director of the Show-Yard, reported that the necessary notices had been issued inviting tenders for enclosing the Show-Yard, and also for supplying the dinner and refreshments in connection with the forthcoming meeting at Cardiff.

THE BARNSTAPLE MEETING, 1859. — A deputation from Barnstaple, consisting of Lord Viscount Ebrington, F. Maunder, Esq. (Mayor), and Messrs. Avery, Harris, Gilbert, and Langdon, waited upon the Council, and represented that the local committee formed for inviting the Bath and West of England Society to that town next year had obtained subscriptions to the required amount (£800), and, in addition to that sum, the deputation were prepared to guarantee on the part of the inhabitants a large number of special prizes for local purposes out of the surplus funds. The deputation elicited from the Council information as to the nature and extent of the ground that would be required for the site of the show-yard and the trial fields; and the Council nominated a sub-committee to visit Barnstaple on Thursday, the 25th of February, to confer with the local committee on the amount of accommodation offered, and to inspect the sites.

NEW MEMBERS.—Rev. W. Beaver, Cowbridge, Glamorgan; Messrs. R. T. Crawshay, Cyrfilla Castle, Merthyr Tydvil; C. F. Williams, Tregullow, Cornwall; H. T. Smith, Devonport; F. Pitts, Alphington, Devon; G. Radmore, Thorverton, Devon; J. Beaviss, Dorchester; W. Partridge, Dulverton; W. Hobbs, Lechlade, Gloucester; E. Spender, Manor Mead, Plymouth; G. May, Modbury, Devon; T. Strong, Dunchideock; W. Farrant, Wellington; Fred. Sharland, J. Collier, J. Knowlman, J. Broom, W. Steer, Culmstock; J. Doble, Buckland St. Mary; J. P. Matthew, Hemyock.

CURE FOR COLIC IN SHEEP.

SIR,—Will you allow me a small space in your columns, that I may communicate to your agricultural readers the following particulars?

I have a number of sheep feeding on Swede turnips with cut hay. An unusual number having been attacked with colic, and every case proving fatal, I determined to try the following remedy: "Ten drops of laudanum, ten drops of essence of peppermint, one tea-spoonful of the spirits of turpentine, and one table-spoonful of sweet oil." I have in no instance found this fail to produce a cure within a couple of hours, although the sheep have been perfectly paralyzed, and unable to stand.

I shall be glad if this suggestion should prove of use to others, and I remain, your obedient servant, J. F.

THE PRESENT PRICE OF CORN.

The prices of agricultural produce vary more than those of any other description of natural productions. Price and value being two distinct results—the first having relation to the amount produced at market—the second to the cost of production.

The rapid decline in the prices of grain, meat, and farm produce of this country at the present moment are not dependent either upon our home production or consumption, or upon both conjointly; but rather upon large importations, and the checking the ordinary transactions of merchants, manufacturers, and traders at one and the same instant, by the derangement of our monetary system; and thus the effects operating upon the corn and meat markets of the metropolis are transmitted to every other local market of the kingdom.

This centralization of the corn markets of Europe, as exhibited in Mark-lane, is transmitted instantly to all the other parts, and consequently *value* as defined by the cost of production, has no relation whatever to it in the result. So long as a large supply of foreign wheat and grain continues to reach our ports, prices will continue to fall, until the average minimum price of the whole of the imports is attained, and *vice versâ*, if a diminished supply falls so low as to produce a scarcity—then and not till then will prices again advance—probably to an extent far beyond the value.

These sudden fluctuations affect the farmer more than any other class of producers, his operations extending over a larger space of time than appertains to others will not allow him to expand or contract his operations accordingly; and it mostly happens that whenever the price of his productions fall to their lowest point, the cost of producing has been carried out at its highest rate—especially as regards rent. To the rent-charge and labour at least a moiety of the whole cost remains unaltered for a long time after prices have so declined—and more especially the tithe rent-charge, which from being based upon an average of the seven years last expired, rises to the maximum point as at present, and so for a time continues whilst grain is at its minimum price.

Tithe rent-charge, by the present arrangement, entered upon for obtaining its averages, acts very injuriously to agriculture; and as it in reality produces no beneficial result to the receiver, there cannot be any reason adduced why an alteration should not be made in the mode of deducing the averages—and the merely reducing them from seven to three years would at once effect an object, so desirable and to be attended with equitable and beneficial results to both payer and receiver.

When we review the principal causes of fluctuation in the marketable value of farm-produce, it becomes apparent that not only tithe rent-charge, but rent also ought to be subject to a like adjustment. But beneficial as such a change might be, little doubt exists that it would not only be objected to, but be absolutely refused by the majority of occupiers, so adverse are they to any change, however beneficial it might be to their future interests. Indeed, when we refer to fluctuations that have occurred in the last ten years, it is matter of astonishment that such prejudices should exist; the reason, probably, arises from the human mind invariably viewing past events as not likely again to occur. Hope leads everyone to expect a change for the better, and therefore the chances of an advance on prices, without having to make a corresponding advance on rent, far outweigh the probability of a decline in prices attended by a corresponding reduction in the quantum of rent.

In the year 1846 we find that prices ran from a low range suddenly to a high one, the extremes being fully 100 per cent.; in the following year they again fell in like ratio, continuing with slight fluctuations until the war commenced with Russia, in 1854, and then gradually rising until the year 1857. Thus they remained until the autumn following, when they again fell to fully 50 per cent.

The fluctuations during the present century have amounted to 400 per cent. and upwards. Wheat has reached £10 per imperial quarter, and has fallen below £2 per quarter, and other produce in nearly equal proportions. "What has happened since may happen again"—if not to the same extent, still sufficiently to require us to guard against the contingency.

In commencing this article we adverted to the effects produced throughout the kingdom by the fluctuations in prices upon Mark-lane, and the influence they produce upon prices in local markets. It ought now to be borne in mind by all agriculturists that the supply of English grain will, during a time of peace, have but little influence upon prices. Mark-lane has now become the emporium of Europe for all descriptions of grain, and the average prices in that market will be governed by the average prices of the continental markets, subject to the addition of cost, freight and profit. But inasmuch as the supplies may far exceed the demand at certain periods, the losses attendant upon importation will be extended to the producers of this kingdom, and will so continue until a reaction is produced, and supply and demand have changed their relative positions.

It, therefore, behoves the British cultivator to weigh these remarks as they deserve. It is now quite certain that the prices of agricultural produce must depend upon the quantity imported; and that the prices of English grain cannot, under the most favourable circumstances, in future far exceed those of the continent of Europe. Whilst, upon the other hand, a large influx of foreign wheat upon the market may cause them to descend far below their intrinsic value, even to such an extent as to prove most ruinous to our home producers.

TITHE COMMUTATION TABLES.

Mr. Willich, the Actuary of the University Life Office, has lately published his Annual Supplement to "*The Tithe Commutation Tables.*" The value of tithe rent-charge depends on the septennial average prices of wheat, barley, and oats. As it may interest our readers, we insert from one of Mr. Willich's tables the annual average prices per imperial quarter during the last seven years, viz.:

	Wheat.		Barley.		Oats.	
	s.	d.	s.	d.	s.	d.
1851	38	6	24	9	18	7
1852	40	9	28	6	19	1
1853	53	3	33	2	21	0
1854	72	5	36	0	27	11
1855	74	8	34	9	27	5
1856	69	2	41	1	25	2
1857	56	4	42	1	25	0

The Quarterly Averages for 1857 may interest our agricultural friends who have let their land at corn rents.

SWING *versus* WHEEL PLOUGHS.

It has been long acknowledged that in the multitude of agricultural implements to be met with on the south of the Tweed, there are many which, if not absolutely valueless, can, at the best, be only designated as expensive toys. At the present moment, the writer has an instance before his mind, of a gentleman who is undoubtedly the leading agriculturist of the county in which he resides, and in whose lumber shed the array of cast off implements (many of them brought out by first-rate makers) would form no mean adjunct to the attractions of a moderately strong agricultural exhibition. A prejudice has hence arisen in the minds of many Scottish farmers against the use of any English manufactured implements. Now, there are amongst us thrashing machines, haymakers, drills, manure distributors, cultivators —nay, even ploughs, which, we hesitate not to say, would be a decided acquisition, if freely used by the go-ahead agriculturists who can afford to pay such long rents on the other side of the Border.

It is with the last-named implement that we have at present to do. Often have we, in days bygone, when living at the foot of the Grampians, heard it sneeringly observed by Scotch ploughmen, with reference to their English brethren, that "they needed wheels to make their ploughs go staight." Now, there is a mistake here; practice shows that there is such—for actions speak louder than words. We have known Scotch ploughmen in several English counties; but we have ever seen that they speedily appreciated the value connected with the easy adjustment and guidance of a well-made Howard's, Ransome's, or Ball's wheel plough. We have known several cases of Scotch ploughs being *imported* to the midland and western counties, though we know not one of them now seeing actual service. In Warwickshire, the favourite plough is that manufactured by the eminent firm, Messrs. Howard, of Bedford. At the last county ploughing match, nineteen-twentieths of those entered were of this make; and we question whether, in the best districts of Scotland, under equal circumstances, better work could have been accomplished. In Class 3 were boys that in the north would not be regarded as fit to do more than rake after a couple of scythes in harvest, or feed the cows on a small farm in winter. These were ploughing, and ploughing well. Now, we do not here enter into the question as to whether it is desirable to employ such *ploughmen* or not. *That* would involve several considerations. We only ask whether such a turn-out could have been made with swing ploughs? We think not. This then—for the work was well executed—proves their ready and efficient adjustment. And is not an implement the better, and the more manageable for being readily and easily adjusted?

In the matter of draught, we are unable to refer to any dynamometrical results, and have only personal judgment to go by. Our belief is, that in drawing a good wheel plough, well set, there is less labour expended than with the swing plough. Then there is the fine level bottom, or floor, obtained for the furrow—"a point in which many Scotch ploughs are sadly deficient." Also that most useful adjunct, a skim-coulter, to aid in burying clover, grasses, or other vegetable matter. Again, the excellent fastening to the coulter, so decidedly superior to the stone-and-wedge system. Likewise the case-hardened share, which, by having its upper surface softer than its under one, naturally continues sharp by the act of wearing, and thus saves many a journey to the smithy. Any of the wearing parts of the plough are readily renewed by a common country blacksmith, the fittings being obtained from the manufacturers.

It will be observed that these remarks have chiefly referred to the Bedford ploughs, though they are not, assuredly, intended as derogatory towards others. We speak from no personal feelings; the Messrs. Howard we are unacquainted with, and we have only written as to what we *know* of their implements. Still, a false delicacy need not prevent us saying to Scottish farmers, "Give Howard's ploughs a trial—a fair and honest trial it will be, for the Scottish maxim is, 'A fair field, and no favour'—and we doubt not but the results will be satisfactory."

In conclusion, we would quote the words of one who knows the subject well, and who says, "With many, particularly the Scotch, the wheels are a fatal objection; their plea is, that they are an unnecessary complication, and that the weight and draught are thereby increased." With regard to the latter, it was shown at a late meeting of the Highland Society of Scotland how ill-founded was the prejudice, for the only English plough competing was proved to draw one-third or one-fourth lighter than the best Scotch plough exhibited, besides performing its work in a very superior style. How can it be, ask some, that a wheel-plough can take less power than a swing, whilst you have so much more weight to draw? This has been a vexed question for years, whilst the thing lies in the smallest possible compass. All ploughs are constructed with a certain inclination to go down into the soil. In a wheel-plough this tendency to draw into the soil is regulated, or obviated, by the wheels, which turn the weight thus thrown upon them, relieving the friction on the point and sole. On the other hand, the swing-plough is kept from entering the soil too deeply by the ploughman, whose whole weight is often required upon the handles to maintain the proper depth. It will at once be seen that this weight at the end of so long a lever throws much additional friction on the sole, which is of itself sufficient to account for the great difference in draught. The objection with regard to complication is purely ideal, the wheels being readily adjusted to any required depth and width, and in the midland counties of England we have seen mere boys using them, and making most beautiful and uniform work.

THOS. BOWICK.

Kenilworth, Jan. 14th, 1858.

HOW TO FARM CLAY LANDS.

SIR,—"Lucus a non lucendo" is, I believe, something like a dark lantern, and is well represented in the phrase of "carrying coals to Newcastle."

I ventured last year to give some general advice to one o your correspondents, who was burdened with 500 acres of clay land; now, strange as it may appear, I, then an oracle, wait for a response on the very same subject. The question I now beg to propose for consideration is how to farm clay land of *inferior* quality at a profit, with wheat at a low price, and every probability of a still farther decline in its value. Many valued productions I have read, offering all sorts of profitable systems and suggestions for the cultivation of clay soils; and in many cases I have felt convinced that the writers on the subject know very little practically as to the capital needed to effect the utter change, both on the part of landlord and tenant, which their advice would require.

First, I wish to explain the nature of the clay soils, for the profitable cultivation of which I should be glad to receive suggestions, based on practice, conveying a system which any tenant farmer with fair average means may safely adopt. The soil I refer to, is met with in large tracts in the Midland counties amongst others, is about five inches deep, with a yellow subsoil, and rubble or clay stone below, generally full of water.

Secondly, I must state that, as far as my experience goes, "circumstances over which there is no control" or "urgent private affairs" seem generally to be pleaded as excuse for that indispensable article in expensive cultivation of this description of land—viz., "capital."

A tenant with large capital will seldom engage in such an undertaking, except with a long lease and at a very low rent; and often a landlord's "burdens" prevent him indulging in the improvement of his property at the expense of his income.

Hence, for a tenant with ordinary capital, say £10 per acre, farming this sort of land and drained in an effectual manner, with buildings and accommodations usually met with, advice is respectfully asked, from some of those who in the time of low prices, found they could work with a profit. For final particulars, broad clover, except with the interval of many years, cannot be grown with certainty; beans also have not depth of soil sufficient to insure a crop. There is one plant, however, always present to give a relish to the crust—the wild garlic or crow onion.

If no kind friend comes forward to solve doubts and questions that are raised, I must fain hereafter trouble you with a few facts drawn from costly practice, and for proof substantiating say "Experto crede."

Yours obediently, G.

MR. RAREY, THE AMERICAN HORSE-TAMER.

When the sportsman or the horseman, who has studied the animal all his life, and knows too well his freaks of temper and easily alarmed disposition—when such a one is told that the worst-tempered brute that ever was handled, or the greatest savage that ever was put into a box, can be conquered and quieted in five or ten minutes—when simply by leaving with him, for some such space of time, an unassuming young man, all the vice is effectually taken out of him—and when he hears, moreover, of there being no perceptible means by which this is accomplished, but that the thing is merely "a secret"—When, we say, a sportsman reads or is told of all this, what in ninety-nine times out of a hundred will he do? With a pleasant smile, and a slight shrug of the shoulders, he will most likely answer at once that "it must be humbug." Or, if he does not say so, he is sure to think so, which comes to very much the same.

Now there is just one step beyond this. He must exercise another of his senses before he quite condemns the discovery. By this, thanks to *The Times* and other channels, he has no doubt *heard* a good deal of the horse-tamer; but if our friend is a practical man, as we will take him to be, he will go a step further, and *see* him. He will judge for himself, as many have already. He will go something more than sceptical as to what is to be palmed-off on him, and he will come away convinced, at least, there is a great deal in it. We state this as the general impression left on all who have hitherto seen the effects of Mr. Rarey's system, and we give it as our own. Horse-tamers and Whisperers are, or have been, by no means unknown amongst us; and we walked into Mr. Anderson's yard quite ready to assure ourselves that we were going to witness some clever trick, or some individual exhibition of personal power of hand or eye, that might be as curious and amusing, perhaps, as a scene in the Circus, and that would be all.

We found the exhibiter, a young well-made American, just recognizable from the tone of his voice as a States-man, in an inner yard in company with a goodish-looking black horse. In one word, he was doing just what he pleased with this animal. And there stood Mr. Anderson and Mr. Rice ready to assure you that a week since they, with all their knowledge of their business—George Rice with all his fine temper and fine hands—could do nothing at all with him. He had been sold, and returned as restive and unmanageable, and there was no help for it but to take him back. He was one of those sad brutes, that with all the look and power of two or three hundred guinea horses, sink down into street cabs sheerly from the impossibility of ever being able to trust them. Mr. Rarey wanted a patient, and here was one that promised to try all his art. He requested only one quarter-of-an-hour's conversation with the unreasonable creature; at the end of that time the black horse was black only in colour. His nature was changed, and the devil fairly gone out of him. We saw what we write. We saw this violent-tempered animal that had been, stand quietly in the middle of the yard, with a plain hard-and-sharp in his mouth, and the rein hanging loose on his neck—and we saw the American wheel a heavy barrow straight up to his head and round him, without the horse flinching in the least. Then the horse-tamer cracked a carriage-whip over his head, and still the animal stood as placidly, and, apparently, as unconcerned as ever. Mr. Rarey next proceeded to mount him, and here perhaps to a sportsman was the most pleasing part of the whole performance. With the rein still loose on his neck, the horse moved and turned, just as the rider moved his hand. We have all seen a "wonderful pony" in the Circus stop and twist round in obedience to the promptings of a tolerably well-pointed whip. But there was nothing of this sort with Mr. Rarey. There was no effort on his part, and there was nothing anxious or nervous in the look of his horse. In fact, he was so calm, his eye so steady and so much at ease, that it was difficult to imagine he ever could have been the vicious obstinate brute too many could speak to. "The manner" of the horse gave one more the notion of an old family pony, not so much subdued, as won over by kind treatment and long usage. You got on him "any-how," and got off him "any-how." One old sportsmen mounted the horse with his half-cigar in his mouth, and slid down again over his tail. A week since the same horse would have kicked his brains out, could any man have been found fool-hardy enough to attempt such an act. Mr. Rarey concluded this demonstration of his power over the horse by taking him into a stall, and lying down by his side—knocking his hoofs together—pillowing his head on his quarters; with similar feats, not quite so seemly to look at, although all tending to prove his complete subjugation of the animal.

The horse-tamer declares his means are simply rational and kindly treatment. He denies the use of any drug, or appliance that can in any way injure the proper spirit or true nature of the horse. He maintains his secret can be imparted to others, and can be as effectually used by them as by himself. And he guarantees that a horse once conquered is conquered for ever. It is only fair to say that the recent performances before her Majesty and the Court all tend to confirm this. Lord Alfred Paget, to whom the secret has been entrusted, has already appeared as a successful practitioner of the art, while the horses operated upon have shown no disposition to return to their former evil ways.

We must repeat there is a good deal in this—more than many a man who has been contending all his life with vicious and restive horses will like at first to admit. It is suggestive, however, at least, that no one who has seen the effect of what is done, but has gone away with a very different opinion to that he entertained on only hearing of it. Mr. Harry Hill, who strolled in to witness the experiment with very doubting eyes, ended by asking if his colts could not be broken on such a principle? Of course they can. Horses shy of water can be made to face it, and, indeed, to do a vast deal more than we mean to tell of here, purely because we do not want to have our word questioned. On the first available opportunity let every one go and judge for himself. Mr. Rarey is accompanied by Mr. Goodenough, who, we will answer for it, from our own experience, will treat every application made to him with all proper courtesy and respect.—*Sporting Magazine for February.*

SIMPLE REMEDY FOR THE PLEURO-PNEUMONIA.

SIR,—Being a constant reader of your valuable paper, I have seen several remedies recommended for that fatal disease called pleuro pneumonia, which is now so prevalent amongst cattle and sheep, in all parts of the country, to the great loss and almost ruin of many stock masters; and which I think may be, in many cases, prevented by a little attention and the following treatment, which I have applied for many years, with great success; indeed, I never knew it to fail, if properly carried out; and I have had some little experience, having had the management of stock and sheep for many years in different counties. The pleuro-pneumonia visits us at all seasons, but, generally, most in the autumn or winter—no doubt from the foggy and wet state of the atmosphere, which affects the lungs, particular of those that are pre-disposed; therefore, about the last week in October, when the stock are generally taken into the yard, I give to each beast, according to size and age, from half-a-pound to a pound of Stockholm tar, and a handful or two of salt, mixed; taking care, at the time, to rub it well into their nostrils. This I repeat once a week, if the disease is prevalent near us, only in less quantity; if not, I repeat it once a month, and at all times, when I buy in a fresh lot of beasts, give them a dose of tar and salt. When I first heard of the disease, we had about 90 head of cattle, and had a two-yr old heifer attacked, which died in four days. The disease was very destructive all around the neighbourhood; I gave all the other stock a dose of tar and salt, and we had no more taken. I then recommended the same dose to my neighbours, and had the pleasure of seeing the same result. There is no doubt about the disease being contagious; I therefore advise all persons who keep cattle, to be particular in keeping the houses and sheds clean, and lime-washed once a year at least. For sheep, I give about two table-spoonsful of the same, with the like result. Any gentlemen who may think proper to try this simple preventive, will find themselves amply repaid for their trouble, and if they will please to make known to me the result, I should be greatly obliged. What I have stated is from my own practical experience; and if you think it worth a small space in your valuable pages, I should take it as a great compliment to myself, and hope it would prove a benefit to all.

I am, sir, your humble servant,

R. MAYSTON,

Bailiff to Mrs. DIXON, Stansted Park.

Emsworth, Hants.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR FEBRUARY.

This has been a remarkably fine month for all out-door farm operations. In most parts of England they have progressed steadily, and are now quite as forward as in the general run of years. Thus far, matters are satisfactory; but, if we turn our attention to the state of the grain trade, we shall find matter for serious consideration. Not that the fall in the value of produce since we last wrote has been extensive—indeed, the fluctuations in prices have been comparatively trifling—but in various quarters gloomy anticipations have been indulged in as regards the future. Wheat is now about the cheapest article of consumption, and present appearances of the trade certainly indicate future depression, notwithstanding that the manufacturing industry of the country is recovering from the late panic, that money is very abundant and cheap, and that consumption has somewhat improved of late. There are, however, influences at work calculated to prevent any upward movement in the quotations. In the first place, the stocks of wheat in the hands of our farmers are unquestionably large for the time of year; in the second, the French markets continue to be heavily supplied with all kinds of produce; and, in the next, we have as yet received but a limited quantity of wheat from the United States, the growth of 1857. In that year the yield was an unusually fine one, both as to quantity and quality; but the movement to the shipping ports, owing to the commercial panic, was very small during the last three months of the season. For instance, since the 1st of September the shipments of wheat were only about 3,000,000 bushels, against over 7,000,000 bushels in the corresponding period in 1856; hence, present stocks in the United States are very large, and prices continue to rule low. In France, too, nearly the same state of things prevails, and the fall in the quotations since the 1st of July has been *forty-one per cent.*; nevertheless, with open ports, or nearly so, present prices are eagerly accepted by the growers. The fact is that the French agriculturists and millers have been dissappointed as regards the effects of the new law permitting the export of produce. They, at one time, looked forward to considerable excitement in the trade and consequently to higher prices, as the result of the permission given to ship grain and flour; but they appear to have overlooked the fact that the growth of corn last year, in all the grain districts of the world—and especially in this country—was the largest on record. True, the partial failure of our potato crop might be taken as a proof that more grain would be consumed; but as the growth of potatoes on the continent has turned out very large, and as immense quantities have been shipped to this country during the last two months in fair condition, the losses have been thus partially met by the foreigner. But even on this important matter much might be written, and, if our information be correct, it would now appear that the actual losses have not turned out soextensive as they were at one time supposed. At all events, there is no actual scarcity of English potatoes, though we admit that their quality is not such as to command what may be termed a ready market. What, then, shall we say in reference to the probable future range in the value of wheat and other articles? It must be admitted that there is no scarcity of supply either here, in France, or in the United States. The supply, we are of opinion, will be found more than equal to general consumption, and if the system—still persevered in to an unusual extent, more especially in reference to the importations from the north of Europe—of selling at any price, be continued, it is impossible to say at what figure the downward movement in wheat will stop. But even with present abundance, it appears to us that it is absolute folly for the foreign growers to inundate our markets with more produce than the demand can take off. Fortunately, our farmers have acted upon the defensive principle; in other words, they have declined to thrash out larger quantities of wheat than the local millers are able to take off; still, there is one important element wanting in the trade, viz., speculation, which, with moderate arrivals, might again be in the ascendant, and give an additional, perhaps an important, tone to the trade.

Barley continues to be in fair request, and the quotations, compared with wheat, rule somewhat steady, although the exports of grain-spirit to the continent have fallen off to some extent. Most other kinds of spring corn have supported previous rates tolerably well, yet the currencies of inferior oats have had a drooping tendency. From Ireland the shipments of oats and other articles have been on a very moderate scale; but from Scotland, large quantities of wheat, barley, and oats continue to be forwarded to the south.

The cattle trade has been in a depressed state both in London and in the provincial markets, and prices generally have given way. The supplies of live stock exhibited in the metropolitan markets have not increased in number, though there has been a decided improvement in the weight and condition of the beasts; still the great falling-off in the consumption of meat in Manchester, Birmingham, &c., has had the effect of inducing many parties to forward unusually large quantities of meat to Newgate and Leadenhall. These supplies have been disposed of at low prices, and consequently the consumption of London has been chiefly met by country-killed supplies.

Although the supplies of hay and straw have not increased, the demand has fallen off and prices have given way. Meadow hay has sold at from £2 10s. to £3 16s.; clover do., £3 10s. to £4 16s.; and straw, £1 4s. to £1 9s. per load.

For all kinds of foreign and colonial wool the demand has been in a most unsatisfactory state, yet the decline in prices has not been extensive. English wools have met a slow inquiry on former terms. The present stocks of colonial in London are 28,175 bales, viz.: 5,186 Sydney, 7,634 Port Philip and Portland Bay, 390 Adelaide, 7 New Zealand, and 14,758 Cape. In addition to these supplies, there are in warehouse 1,145 bales East India and 297 China. It is a remarkable fact that not a single bale of Van Diemen's Land wool is on hand.

The root crops are lasting well, and very large quantities are now offering at low prices. In some parts of the country large patches of turnips are offered for sheep-feeding free of expense.

In Ireland and Scotland the wheat trade has ruled heavy, and prices have continued to give way; spring corn, however, has supported previous quotations. For stock-feeding the weather has been favourable.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that the metropolitan market has been very moderately supplied with beasts and sheep, more especially with the latter, during the whole of the month, trade generally has been depressed, and a fall of from 2d. to 4d. per 8lbs. has taken place in the quotations. Even at that amount of depression, the butchers have purchased cautiously, and wholly for present wants. This state of the trade has induced the opinion in some quarters that consumption in London has greatly fallen off. Such, however, we believe is not the case, since we find that the receipts of meat from our provinces, as well as from Scotland, have been considerably in excess of most corresponding periods of the year. No doubt consumption in our manufacturing districts has seriously declined, and this fact has induced those who have been in the habit of supplying Birmingham, Manchester, &c., somewhat liberally, to turn their attention to London, and the low charges by the various railway companies for the conveyance of meat, viz.,

one penny per ton per mile, have had the effect of increasing the supplies to a considerable extent. Then, again, we must not forget that wool, hides, and skins are worth more in some parts of the country than in the metropolis; so that, although meat in Newgate and Leadenhall has been sold at very low prices, there has been no actual loss, in a comparative sense, in the present increased mode of supplying the wants of London.

In Holland, and on some other parts of the continent, stock is now relatively dearer than in England; consequently the importations into London have exhibited a further decrease. Last month they were as follows:—

Beasts	714	head.
Sheep	822	,,
Calves	784	,,
Total	2,320	head.
Same time in 1857	4,720	head
,, 1856	3,087	,,
,, 1855	2,839	,,
,, 1854	10,683	,,
,, 1853	12,433	,,
,, 1852	9,123	,,
,, 1851	11,828	,,

Thus it will be seen that we have received an unusually small importation, the falling off, compared with February, 1853, being over 10,000 head.

The total supplies shown in the great Metropolitan Market have been as under:—

Beasts	18,276	head.
Cows	466	,,
Sheep	69,070	,,
Calves	1,091	,,
Pigs	1,559	,,

COMPARISON OF SUPPLIES.

Feb.	Beasts.	Cows.	Sheep.	Calves.	Pigs.
1857....	17,629	457	74,430	1,172	1,975
1856....	19,642	495	99,950	673	2,614
1855....	17,436	385	91,180	596	2,705
1854....	20,091	520	92,441	1,023	2,279
1853....	19,308	470	86,910	2,098	2,420

This comparisou shows that the supply of sheep disposed of has been smaller than during the last five years.

From Norfolk, Suffolk, Essex, and Cambridgeshire, 10.020 Scots and short-horns came to hand during the month. From other parts of England the receipts were 3,850 of various breeds, from Scotland 2,340 Scots, and from Ireland 1,012 oxen and heifers.

About 1,200 shorn sheep have made their appearance in the market, and which have sold at from 6d. to 8d. per 8lbs. beneath those in the wool. It is to be regretted that shearing should be commenced at so early a period, because it frequently happens that the loss upon each head is fully 2d. per 8lbs., as the butchers are never disposed to purchase stock out of the wool during inclement weather. Wool may be worth more in some parts of the country than in the metropolis; but our impression is that the flockmasters lose money by early shearing—that is to say, if the sheep are intended for immediate sale.

Beef has sold at from 3s. to 4s. 6d.; mutton, 3s. 2d. to 5s. 2d.; veal, 4s. to 5s.; pork, 3s. 2d. to 4s. 6d. per 8lbs. to sink the offal. In the corresponding month in 1857, the best beef realized 5s, the best mutton 6s., the best veal 5s. 8d., and the best pork 5s. 2d. per 8lbs. The fall, therefore, compared with last season, is a serious one, and many of the graziers who bought store animals at high rates are now losing money.

Nearly 40,000 carcases of meat have been received up to Newgate and Leadenhall markets during the month. The trade generally has been in a most depressed state at drooping currencies.

Beef has sold at from 2s. 10d. to 4s. 4d.; mutton, 3s. to 4s. 6d.; veal, 3s. 6d. to 4s. 6d.; pork, 3s. 2d. to 4s. 6d. per 8 lbs. by the carcase.

Letters from Holland state that the supplies of stock likely to be shipped to this country during the present year are still limited, that prices rule high, and that purchases of both beasts and sheep still continue to be effected on French account. In the north of Europe the supplies have rather increased, but in France meat is still ruling high. Apparently, therefore, there is no prospect of our receiving large importations between this and the end of the year; indeed, it is possible that we shall have to report even a further decrease in them. The demand, therefore, will be chiefly met from home sources, and it occurs to us that the late fall in the quotations will be shortly recovered, though we admit that prices during the coming season are likely to rule moderate.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

APPLEBY HORSE FAIR.—A few very good animals were shewn, and for some, good prices were obtained.

BANBURY FAIR.—The supply of beef and mutton, of all kinds, is very good, and although sales are complained against by a few, yet the trade done may be considered satisfactory, prices being much the same as last fair. The quality of the cattle is really excellent, and best things met with a speedy sale.

BEDALE FAIR.—We had a thin show of fat stock, which sold readily at rather higher prices. In lean stock and in-calvers there was also a short supply, but they sold well, and prices remained unaltered. Beef, 6s. to 7s. per stone; mutton, 5d. to 6d. per lb.

BEVERLEY FAIR had a good attendance of buyers. A limited supply of first-class horses had ready sale; a good show of medium and inferior ones had dull demand and prices low. A very limited number of cattle had slow sale, and prices still lowering.

BRIDGNORTH FAIR was very depressed, the supply of stock being very small, and the attendance of dealers smaller than usual. Sheep sold from 7d. to 7¼d., and some fine ewes went as high as 7½d. Cows sold from 6d. to 6¼d. Cows and calves were about the same as last fair. Pigs continue low. The horse fair was ill supplied; and what stock was there was in very bad condition. The highest price fetched for small waggon horses was 30*l*.

BROUGH FAIR.—There was a large show of well-bred beasts, and a number of influential buyers and jobbers, but all seemed inclined not to give the prices asked, which soon caused a different aspect, and the market became flat, and was much down compared to the fair held in January; except calvers, which went off well. Groups of cattle were unsold.

CARLISLE HORSE FAIR.—The display of horses on this occasion surpassed anything of the kind for the last thirty or forty years, both as to numbers and quality, the market being quite full. The number of saddle horses was not very great, neither was the quality of this class first-rate. We do not remember having seen a smaller number of old and low condition animals on a similar occasion. The amount of business transacted was not so extensive as might have been expected, and price had a downward tendency.

DEVIZES FAIR.—The show of worked-off oxen, suitable for grazing purposes, was large, and sold at about £2 in £20 less than last year; at this reduction a fair trade was done, although a few lots were taken away unsold. Barreners, in-calvers, and milch beasts were in short supply, and sold at about £1 per head less money. Beef, from 10s. to 11s. per score. The great feature at this fair was the worked-off oxen; and it is admitted, we believe, on all hands, that a few years at the plough is decidedly beneficial for grazing, and improves the flavour of the meat if not worked too long. As regards the horse fair, we cannot say much. Mr. Edmonds, of Wroughton, sold two or three good cart horses, and we heard of one or two useful nags being sold in the stables; in other respects little business was done.

DORCHESTER FAIR was scarcely so large as on previous occasions; but business may be fairly said to be brisk, and on every description of stock prices were good, and a more than average amount of business was done.

DUMFRIES HORSE FAIR.—The number of horses was at no time greater than 300, or about a fourth less than the number brought forward last year, and, as usual, they were almost entirely draught horses. The general proportion of very good horses was not great, and the fall in that class was not more than 15 per cent. from the rates of last February. On secondary stock the reduction was at least 20 per cent.; on third class about the same; while for lower grades there

was no demand. Mr. Foster sold 10 on Monday to another dealer at prices varying from £40 to £50; and he was asking £60 for a fine draught mare, for which he could have got upwards of £70 last year. Messrs. Teenan and Clarke sold a grey mare for £52; a powerful horse for £53; another mare, a splendid animal, for £56, the buyer in the latter instance having been a farmer from the neighbourhood of Kirkcudbright; and they also disposed of 4, about £50 each, to a purchaser from Peeblesshire. Mr. Brown, Hardgrave, sold a pair of beautiful draught horses for £100; and Mr. Carruthers, Broklehirst, sold another similar animal for 50 guineas. Such are some of the transactions in the best class of horses; for other kinds a degree inferior the prevailing rates were from £30 to £40; and a considerable proportion of good animals for farming labour changed owners at £25 and under.

EGREMONT HORSE FAIR was very thinly attended, both of horses and purchasers.

EXETER FAIR was numerously attended by farmers and dealers, and well supplied with cattle of the primest quality. Perhaps the number of dealers present was greater than butchers or consumers wished to see. There was no alteration in prices. The best fat beef realized from 9s. 6d. to 10s. 6d.; barreners, 7s. to 8s. per score; cows and calves, £12 to £18.

GLOUCESTER MONTHLY MARKET.—The supply of beef was large, but of inferior quality, and a flat sale; of mutton the supply was good, and the whole was soon disposed of. Beef, 6d. to 6½d.; mutton, 7d. to 7½d. per lb.

KELSO FORTNIGHTLY MARKET.—There was a good show of fat cattle, and several of the lots were of excellent quality. There was a good attendance of buyers, with a brisk demand, and nearly the whole were quickly cleared off at prices a shade better than our previous market. Beef may be quoted at 6s. 3d. to 6s. 9d., and a few superior brought about 7s. per stone. There was a small supply of sheep, which sold readily at 6½d. per lb. A fair show of cows, which were selling at from £10 to £16.

LEDBURY FAIR.—The supply of stock was rather short. Some prime fat cows were offered, which realized good prices. Buyers were numerous, and most of the stock offered was sold at an early hour. Fat cows, 6½d. to 7d.; ditto sheep, 6½d. to 7d.; store ditto, 26s. to 36s. each; fat pigs, 8s. 6d. per score; store ditto, 26s. to 36s. each.

LEOMINSTER FAIR.—There was not a large quantity of fat beef; the highest figure was about 6½d. per lb. Best wether mutton brought 7d. per lb. There were many buyers of stores, and good barrens brought full prices.

NEWTON STEWART HORSE FAIR. — There was scarcely the average number of horses, and very few sales took place, farmers wishing to obtain the prices of the last two or three years; but any sales which took place were from 15 to 20 per cent. less. There were very few dealers present.

NORTHALLERTON FAIR.—A thin show of all descriptions of stock, with plenty of buyers. Lean beasts sold at lower prices. Beef, 6s. 3d. to 7s. per stone. The number of horses shown was very great, and dealers from all parts were numerous. Several first-rate hunting and carriage horses were readily sold at high rates, and inferior ones 20 to 30 per cent. lower than last year. Draught horses were in demand, at good prices.

OXFORD GREAT MARKET.—There was a short supply of good beef and mutton, and as the demand was rather considerable all went off at prices quite as high as last market—beef, 4s. 4d. to 4s. 8d.; mutton, 5s. to 5s. 4d. per stone. Store cattle and sheep were not so plentiful as on former occasions, and a dulness prevailed, very few changing hands. The pig market was unusually dull with a short supply—good English hogs from 8s. 6d. to 9s.; porkers 9s. to 9s. 6d. per score.

PENRITH HORSE FAIR.—There was a tolerably large show of farm horses, and a quantity of old hacks. The business doing was very limited, and prices much below those of last year. For a very superior animal we heard of £40 having been offered.

RUGBY FAIR.—There was a good supply of beef, at from 5½d. to 6½d.; a short supply of mutton, from 6d. to 7d. Store beasts easier to buy. A short supply of horses, at low prices.

SHREWSBURY FORTNIGHTLY MARKET. — The best fat heifer beef sold from 6d. to 6½d. per lb.; fat calves, 6d. to 6½d. per lb.; useful store cattle selling at fair prices; also good cows and calves at high figures. Fat wether sheep, 7d. to 7½d. per lb. Fat pigs, 5d. to 5½d.; store pigs still very low.

TEWKESBURY FAIR was very well attended, and a large supply of stock, mostly fat. Demand limited, and sellers had to dispose of their stock at very low prices. Beef sold at 5½d. to 6d.; mutton, 6d. to 6½d. The horse fair was thinly attended, and what sales were made were at very low figures.

YORK FORTNIGHTLY MARKET.—Calving and dairy cows, and all kinds of grazing beasts, had fair ssle, at former rates. A moderate supply of fat beasts sold at 6s. 6d. to 7s. per stone. A fair show of mutton sheep went at 6d. to 6½d.; superior ditto, 7d. per lb. A good supply of grazing sheep had fair demand: hog sheep, 22s. to 43s. per head. The market is a little on the improve.

CALENDAR OF AGRICULTURE.

Sow oats and barley on dry and early lands during dry weather; also spring wheat, vetches, peas, beans, and flax-seed. Sow lucerne on well-prepared ground, trenched or very deeply-ploughed and richly dunged. Sow carrots and parsnips on good warm sandy loams, that are in good condition from previous treatment, without the present application of fresh manure: steep the seeds in leys of urine, and dry them with lime. Sow sainfoin, and dress the young plants with gypsum. Apply artificial manures and top-dressings on young wheats, barleys, and clovers—as soot and salt, malt combs, rape-dust, nitrate of soda, pigeons' dung, and gypsum. Sow cabbage seeds for summer plants, and lay composts on grass lands.

Plant hops, and make the hills six feet distant each way. Use well-rotted dung, and put four sets in each hill, one in each corner, and cover them lightly with earth, leaving the upper end of the set just in light of day.

Continue the planting of forest trees and of young hedges, but cease if dry weather sets in. The cutting of underwoods will now be finished.

Watered meadows may now be stocked with light animals. Set traps for vermin, and spread molehills.

Plough fallows for green crops, and also clay lands for bare fallows, if the weather be dry. Shut up the fields that are intended for hay, and finish laying composts on grass lands. In wet weather thrash grains, and carry dung from the yard to the heaps in the fields.

In many situations ewes will drop lambs very largely in this month. Feed with juicy succulent food, as beet, cabbages, and turnips, and provide a warm shelter, which is equally necessary with the food itself. The shelter sheds must be dry, and frequently littered with short straws and chaffs. Remove the ewes and lambs from the paddock to the pasture field regularly, as the lambs get strong.

Keep the poultry-houses dry and warm, and set all kinds of eggs for hatching. Feed amply, and provide clear spring-water.

Finish the killing of hogs for bacon, and keep all young pigs for summer stores, and for early feeding next winter.

The latest fattening bullocks must now be sold, or pushed forward by superior feeding. The long days will now require a greater supply of food, as daylight always induces animals to eat more.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

The indications of wintry weather which were given at the close of January, after some rapid fluctuations and a moderate fall of snow, were verified in the progress of the past month, which closed with great sharpness. Still, as it has remained on the whole unusually dry, we do not find the promising aspect of the growing wheat abated in this country; but in America the absence of a snow-covering has left the autumnal wheat too much exposed, and it is in some localities presenting a sickly appearance. On the other hand, there were recent complaints from parts of Spain that the crop was impeded in its growth for want of rain, which has since fallen, but not in sufficient plenty. It will not be safe, therefore, to make too sure that another heavy crop will follow the last, as the most critical periods have all to be passed through. The wheat trade has, however, not revived, an ample six months' stock being yet in growers' hands, and foreign supplies being good, notwithstanding the fact that nearly all are either sold to a heavy loss, or placed in granary to prevent it. The money market has indeed passed from scarcity and "high pressure," to a burdensome abundance, with very low rates of interest; but trade and confidence have not yet returned. The month opened with complete depression, and markets have generally declined 2s. to 3s. per qr., and though an impression has been lately gaining ground that the "minimum" price has been about reached, with the country pointing upwards, the sudden overthrow of the Palmerston Ministry may again unhinge the minds of capitalists, and prevent speculative purchases, notwithstanding a fall in the averages to 45s. 8d. per qr. The least probability, however, of a war with our present allies would soon change the face of things, and the plenty now offering in the markets be materially reduced. Lord Derby or his successor will doubtless endeavour to prevent such a calamity, but Orsini's projectile may yet be the occasion of a general flame.

Potatoes have held out better than expected; but as flour is comparatively lower, there must be a larger consumption, and millers keep low in stock, and proportionately dependent on events. Foreign quotations by last advices were as follows:—

France, somewhat improving, quotes the price of good wheat at Paris about 42s. per qr., and flour 31s. per sack, or 1s. per sack below Norfolks. At Seville, flour 50s. per sack; mixed wheat 53s., hard 58s. 6d. per qr. Cadiz: Flour, 50s. 6d. per sack. Marianopoli wheat, at Barcelona, 45s. 9d. per qr.; worth the same here. Ghirka wheat at Odessa was quoted 42s. to 44s. 8d. (selling here at 46s.), hard to 55s. per qr., with a fair business doing against the opening of the port. At Leghorn, native wheat was 48s. 6d. per qr.; Genoa quoting 50s. for Berdianski. Saidi wheat at Alexandria was quoted 27s. 4d.; selling here at 31s. 6d. per qr. The Baltic ports, which are closed except to steamers cutting their way at great expense, show a range of prices nearer to our own; good red at Stettin being procurable at 40s. per qr., fine high mixed at Danzig 46s. 6d. per qr.; but the stock there of all sorts was at present only about 28,000 qrs. Rhenish wheat in Holland was worth 46s. 6d., and in Belgium, good quality ranged from 43s. to 44s. 6d. per qr. New York has a large stock of flour, which was looking down; but wheat was buoyant, white Southern being quoted at 1 dol. 40c. per bush., equal to 48s. per qr.; red 1 dol. 22c., equal to 42s. per qr.

The first Monday opened with moderate supplies of both English and foreign wheat. The morning's supply from the near counties did not exceed an average, the weather being again frosty; but there were many samples left over from the previous week, and a large fleet of foreign vessels being reported off the coast, there was an unusual depression, so that it was necessary to submit to a reduction of 2s. to 3s. per qr., to make any way. Foreign was equally difficult to place; but holders were not so ready to make an equal concession. This account had its effect in the country, but generally the reduction was not so heavy, some places only noting a difficulty in sales; Sheffield and Birmingham making the decline only 1s. per qr., but there was almost a panic at Leeds, at 3s. per qr. less money. Liverpool, on its first market, gave way 2d. to 3d. per 70lbs., without any quotable reduction on the following Friday. Saturday's markets generally noting a fall of 1s. to 2s.; but Friday, in London, was the dullest day known for some time, and a good deal of fine Kentish was sent back unsold.

The second Monday, as respects the addition of foreign samples, was much below the average, with only a moderate quantity of English. This morning, there was a fair show from Kent, with less from Essex. The day was clear and frosty, and highly favourable to the condition of the samples; and those millers who did not avail themselves of Friday's depression, found, for picked samples, they had to pay the prices of the previous se'nnight: but, though more tone was evinced by all holders, it was a poor day as respects business, a good many parcels of English being left on the stands. The tone of the trade improved in London as the week closed, Friday realizing an occasional advance of 1s. per qr. for picked parcels of English and foreign. The country reports varied. Some of the early markets in Lincolnshire showed progress with the downward movement; but the general tendency was to advance. Hull, Louth, York, and several other places, made no change; Birmingham, Boston, Wolverhampton, Peterborough, Derby, and Lincoln were all 1s. per qr. better; Norwich, Leicester, and Grantham noting an advance of 2s. per qr. Liverpool, on Tuesday, was dull, holders refusing to accept lower rates. On Friday, 2d. per

70lb. more was realized, but only on good American red qualities.

The third Monday commenced on moderate arrivals, both English and foreign, with not many additional samples, in the course of the morning, from the near counties. Factors began by asking about 2s. per qr. more money, and in some instances there were sales at improved rates; but as the day wore, the buoyancy ceased, and where any clearance was effected, it could only be said that fully the previous rates were made for home-grown wheat. Picked foreign red, like Rostock or Louvain, was taken at quite 1s. per qr. above the rates of this day se'nnight. The country markets generally were unaltered or rather dearer. Derby, York, Leicester, Grantham, Peterborough, Louth, and Birmingham were firm; Boston, Lincoln, and Lynn, as well as Chelmsford and Gloucester, were 1s. per qr. higher; Market Rasen and Market Harborough quoting an advance of 1s. to 2s. per qr. Liverpool, on Tuesday, kept the previous market's advance, but on Friday gave way 1d. per 70lb., though on the same day in London, 1s. per qr. more was occasionally made.

The last Monday in the month exhibited a better supply of foreign wheat, though the near counties sent up a very moderate quantity. The weather remained clear and frosty, and the condition was improved, but the change in the Ministry seemed to exert a sinister influence, and the rates of the previous week were with difficulty sustained, the market being only saved from a decline by the scanty show of English samples. Leeds and Liverpool on Tuesday tallied with the London report.

The supplies into the port of London in the four weeks have been 16,147 qrs. English, including some Scotch, with 33,969 qrs. foreign; making the weekly average 12,529 qrs., against 20,065 in January; the decrease being chiefly in the foreign arrivals. The foreign imports into the United Kingdom in the month of January, were 342,841 qrs. wheat; 304,688 cwt. flour. The averages have declined from 48s. 8d. to 45s. 8d. in four weeks; the London averages in the same time have receded from 50s. 8d. to 46s. 10d., showing a difference of 3s. 8d. per qr.

The price of Town-made flour commenced at 43s., and remains unaltered. In Norfolks there have been some changes, the second Monday showing a decline of 1s., which was recovered on the third. American and French samples have given way fully 1s. per sack and barrel. The supplies in four weeks were 75,621 sacks English: 6,611 sacks, 7,134 barrels foreign; showing a deficiency as compared with January to the extent of 3,391 barrels, the sacks being about equal.

The fluctuations in the barley trade have been so slight that prices have scarcely changed, but the averages show a decline from 37s. to 36s. 3d. The finest quality of malting has continued scarce on the London market; the middling sorts have been less abundant; and the lower kinds from the East, which have occasionally arrived in large quantities, have been finding vent by the low prices accepted as horse food in mixture with light oats, which in moderate proportions have been found to answer well. Of this there was a large supply in the second week of the month, influencing this description fully 1s. per qr. down, but the closing Monday was more cheerful in its aspect for all sorts, the supply of home-growth being small. During the four weeks the receipts have been 11,382 of our own growth, and 43,523 qrs. foreign, giving a weekly supply of 13,726 qrs., which only shows a slight decrease on the previous month. There were imported into the United Kingdom in January, 94,154 qrs. The lower kinds of this grain may improve as stocks get exhausted, but the lateness of the season is against any advance in fine sorts, though picked parcels for seed went off well at the month's end.

The trade in malt has been heavy through the month even in the finest qualities, inferior descriptions having sold at lower rates.

The oat trade, with below an average supply throughout the month, has continued declining, prices having receded about 2s. 6d. per qr. As noted before, the liberal use of inferior barley, at a less proportionate price, has reduced consumption; while the quantity yet remaining in store, though not heavy now, has served to keep sufficient samples in the market to prevent any brisk inquiry. The first Monday noted a decline of 1s. per qr. An equal fall was noted on the second, and the two other Mondays were rather cheaper. Irish supplies, though almost wanting since the first Monday, have been made up by larger receipts from Scotland, in better condition; and foreign arrivals on the last day were beginning again to appear, being shipped in the mild weather. The arrivals have consisted of 5,403 qrs. English, 19,196 qrs. Scotch, 15,737 qrs. from Ireland, and 32,510 qrs. from the continent—making the weekly average only 17,204 qrs. The averages, however, of this grain show an increase of 8d. per qr., proving that prices have not so declined in the country. The total imports in January were 61,528 qrs.

Beans and peas in the London market, though a heavy sale throughout the month, have undergone little change. New samples of the former first declined 1s. per qr., and then recovered. Peas, especially boilers, have been excessively dull, and the sudden set-in of frost has not at all sent them up. The arrivals of beans during the month were 4,184 qrs. English and 3,340 qrs. foreign, or 1,881 qrs. per week against 3,872 qrs. in January. Of peas, the total foreign receipts were 204 qrs. and the English 1,730 qrs., or 533 weekly against 488 qrs. per week last month. Hog peas have only retained their value by their scarcity and the absence of foreign.

The linseed trade has been steady, only experiencing 1s. per qr. decline; but sales have been slow. Cakes retain their favour, and find a free placement as cattle feed.

The seed trade has commenced, but without briskness, and the first prices of foreign imports have not been sustained, a large supply of inferior English having appeared before the demand came thoroughly on, and there is not much appearance of high prices either for red or white cloverseed this season. Trefoil has been steady. Canary and

hempseed have maintained their value, and the non-appearance of foreign spring tares in quantity has greatly enhanced their value. Reports say the crops abroad have failed; but we think the prices now paying (7s. per bushel) will draw supplies. Mustardseed and rapeseed have been firm; coriander and carraway almost without variation.

WOOL MARKETS.

ENGLISH WOOL MARKET.

LONDON, Monday, Feb. 21.—Since our last report, there has been a moderate inquiry for fine short wools, at full quotations. In all other kinds, the supply of which is only moderate, only a limited business is doing on former terms. For export to the continent nothing is doing.

BRADFORD WOOL MARKET (Thursday).—There has been a tone of quietness in our market during the week, and little business has been done. Spinners having supplied their immediate necessities, pause at the advanced prices now asked. For noils and brokes there continues a fair demand, and prices are firm. Yarns: The export houses continue to buy up anything offering "under the market," but as yet are not prepared to pay the advance now sought, and the spinners, from the difficulties in the way of buying wool, are very stiff in price. Cotton yarns are dearer. Pieces: There has been a fair attendance of merchants, but not much business has been done. Several foreign buyers are over, but their purchases are chiefly confined to fancy goods.

LEEDS (ENGLISH AND FOREIGN), Feb. 19.—The demand for English wool has somewhat diminished, whilst that for colonial has not fallen off. There has been a little improvement in the demand for low foreign, and prices are without alteration.

LIVERPOOL WOOL MARKET, Feb. 20.

Scotch Wool.—There continues to be a moderate demand for Laid Highland, but consumers buy still only for immediate wants. White Highland is still inquired for, but wanted at very low prices, which holders are not inclined to meet. Cheviots and crossed of a good class are in fair demand, but only in small parcels to supply immediate want

		s.	d.	s.	d.
Laid Highland Wool, per 24lbs.		11	6	to 12	6
White Highland	do	15	0	16	0
Laid Crossed	do..unwashed	14	0	15	0
Do.	do..washed	15	0	16	0
Laid Cheviot	do..unwashed	15	6	17	0
Do.	do..washed	18	0	20	0
White Cheviot	do..washed	30	0	32	0

Foreign.—There is now a decidedly better feeling in the trade, and there are a few inquiries, and business doing to good extent, particularly for fine wools: low kinds move more slowly, but all have an upward tendency.

Printed by Rogerson and Tuxford, 246, Strand, London.

ELEGANT PERSONAL REQUISITES.

Under the Patronage of and Royal Family the several Sovereigns

Her Majesty "The Queen," of Great Britain, and Courts of Europe,

AND UNIVERSALLY PREFERRED.

ROWLANDS' MACASSAR OIL

Is universally in high repute for its successful results during the last half century in the GROWTH, RESTORATION, and IMPROVEMENT of

THE HUMAN HAIR.

It prevents Hair from falling off or turning grey, strengthens weak HAIR, cleanses it from Scurf and Dandriff, and makes it BEAUTIFULLY SOFT, CURLY, and GLOSSY.

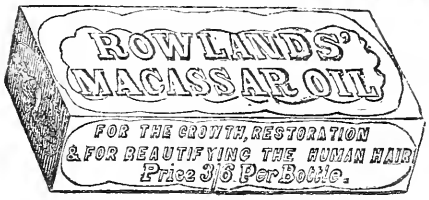
In the growth of

THE BEARD, WHISKERS, AND MUSTACHIOS

it is unfailing in its stimulative operation. For CHILDREN it is especially recommended as forming the basis of A BEAUTIFUL HEAD OF HAIR.

Price 3s. 6d.; 7s.: Family Bottles, equal to four small, 10s. 6d.; and double that size, 21s.

IMPORTANT CAUTION.



To prevent the substitution of *Spurious Imitations* for the genuine article by unprincipled shopkeepers, A. R. & Sons here add a small copy in *outline* of their Label (as it appears round the bottle) from the burin of Messrs. Perkins, Bacon & Petch, the eminent engravers, of London.

Another portion bears the Signature of the Proprietors, in Red Ink—

"A. ROWLAND AND SONS."

ROWLANDS' KALYDOR,

AN ORIENTAL BOTANICAL PREPARATION

FOR IMPROVING AND BEAUTIFYING THE COMPLEXION AND SKIN.

It eradicates all REDNESS, TAN, PIMPLES, SPOTS, FRECKLES, and DISCOLORATIONS, and renders

THE SKIN SOFT, FAIR, and BLOOMING.

It obviates all the effects of Climate on the Skin, whether with reference to cold and inclemency, or intense solar heat' and affords immediate relief in cases of sunburn, stings of insects, or incidental inflammation. Gentlemen after shaving will appreciate its softening and ameliorating properties.—Price 4s. 6d. and 8s. 6d. per bottle.

CAUTION.—The words Rowlands' Kalydor are on the Wrapper, and their signature, "A. Rowland & Sons," in red ink, at foot.

A GOOD SET OF TEETH

Ever insures favourable impressions, while their preservation is of the utmost importance to every individual, both as regards the general health by the proper mastication of food, and the consequent possession of pure and sweet breath.

ROWLANDS' ODONTO,

OR, PEARL DENTIFRICE,

Compounded of the choicest and most recherché ingredients of the ORIENTAL HERBAL, and of inestimable value in

PRESERVING AND BEAUTIFYING THE TEETH,

IMPARTING A PEARL-LIKE WHITENESS,

STRENGTHENING THE GUMS,

And in rendering

THE BREATH SWEET AND PURE.

CAUTION.—The words Rowlands' Odonto are on the Label, and A. Rowland & Sons, 20, Hatton Garden, on the Government Stamp affixed on each box.—Price 2s. 9d. per box.

Sold by A. ROWLAND & SON, 20, Hatton Garden, London, and by Chemists and Perfumers.

THORLEY'S FOOD FOR CATTLE,

AS USED IN HER MAJESTY'S STABLES,

And also on His Royal Highness the Prince Consort's Farm, Windsor.

IMPORTANT TO EVERY MAN

WHO KEEPS A

THE FIRST AND ONLY PRIZE

EVER AWARDED FOR FOOD FOR CATTLE IN A CONDENSED STATE WAS GIVEN BY

THE CHESHIRE AGRICULTURAL SOCIETY IN 1857,

TO JOSEPH THORLEY, ESQ.,

THE INVENTOR AND SOLE PROPRIETOR OF

THORLEY'S FOOD FOR CATTLE!

THIS FOOD is now receiving patronage from all parts of the kingdom, including His Grace the Duke of Richmond, His Grace the Duke of Athole, the Earl of Wilton, the Earl of Eldon, the Earl of Essex, the Earl of Bessborough, the Earl of Aylesford, the Earl of Lisburne, the Earl Rosslyn, Viscount Strathallan, Viscount Dillon, the Right Hon. Lord Willoughby de Brooke, the Right Hon. Lord Londesborough, Lord Lurgan, Lord Macdonald, Lord Saltoun, Lord Greenock, Lord Hatherton, Lord A. Russell, Sir John Cathcart, Bart., Sir John Ribton, Bart, Sir Wm. Payne Galway, Bart., Sir David Cunynghame, Bart., Sir Montague Cholmely, Bart., Sir John Seymour, Bart., Sir Charles Payne, Bart., Sir Thos. Erskine, the Hon. D. Astley, the Ven. Archdeacon Freer, H. Drummond, Esq., M.P., E. Holland, Esq., M.P., Gerrart Sturt, Esq., M.P., General Wyndham, Col. Ames, Col. Cartwright, Colonel C. Hunter, Lieut.-Col. Candley, Lieut. Williams, Lieut. and Adjutant Holland, and many others too numerous to mention.

Converts the commonest of Straw into a superior Provender.

It is requisite you should notice the Inventor's Signature on each package or feed, as inferior sorts are often substituted.

BINGLEY HALL CATTLE SHOW, BIRMINGHAM,

30th November, 1857.

Class X.—FIRST PRIZE.

FED ON THORLEY'S FOOD FOR CATTLE.

DEVON STEERS.

See Catalogue, No. 88.—The property of the Right Hon. the Earl of AYLESFORD.

SECOND PRIZE.

FED ON THORLEY'S FOOD FOR CATTLE.

The property of His Royal Highness the PRINCE CONSORT.

The above are a few of the many Prizes obtained through the use of this invaluable Compound, which is adapted for all kinds of Stock, and now in use throughout the world.

Sold in Cases, containing 448 Packages—each Package one feed—at the cost of 56s. per Case; also in Casks, containing 448 feeds, with measure included, price 50s. per Cask. Carriage paid to any Railway Station in the United Kingdom.

None are genuine without the Signature being affixed to each Package or Feed.

Joseph Thorley

INVENTOR AND SOLE PROPRIETOR.

A

Central Depot.—77, NEWGATE STREET, LONDON.

ROBERT AND JOHN REEVES,
BRATTON, WESTBURY, WILTS,

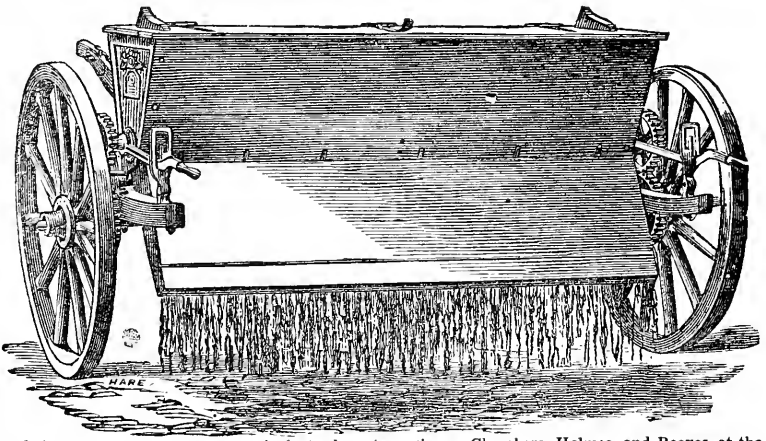
BEG to call attention to their useful Implement,

REEVES'S DRY MANURE DISTRIBUTOR,

which is equal to any for top drilling with all kinds of manure, and is superior to all others for putting in Soot.

PRICE.....£10.

THREE PRIZES were awarded to it last year—at the Bath and West of England Society, Newton; at the Royal Agricultural Society of England, Salisbury; at the Yorkshire Society, at York.



"The Dry Manure Distributors furnished one of the most interesting trials of the whole meeting. Who ever has witnessed the effect of hand-sowing guano on a dry windy March day will not refuse the epithet *humane*, as well as economical, to these inventions. Chambers, Holmes, and Reeves, at the descending scale of 20 gs., £14, and £10, are the names and the corresponding prices that offer themselves; that of Mr. Reeves, at the lowest sum, being introduced first to the Society at this meeting. The machinery of the two dearer ones is most ingenious, and almost inevitably exact in their steady delivery of the manure, whether damp or powdery. But Mr. Reeves' lower-priced implement is a positive boon to the *labourer* as well as the farmer."—*Report on Trial of Implements at Salisbury Meeting, by C. W. Hoskyns.*

CHANDLER'S PATENT LIQUID MANURE DRILL,

After the test of Ten years, is still acknowledged to be the most simple and efficient.

R. & J. REEVES have made arrangements with Mr. CHAMBERS to Manufacture his PATENT LIQUID DROP COULTER, so that those who prefer the bunching system can now have the most complete Drill that has been yet offered to the public.

REEVES' PATENT ECONOMICAL DRILLS,

For Drilling all kinds of Artificial Manure with Roots or Grain, in their pure state, without the expensive system of mixing them with a large quantity of ashes. They will Drill from 2 to 20 Bushels per Acre, and will be found very useful when water is too scarce to use the Liquid Drill, and also on light down land. Prices from £8 to £14. They gained Two Prizes and a Silver Medal last year (being their first year).

REEVES' PATENT HAND DRILL,

For Gardeners, Market Gardeners, and small Occupiers, will Drill or Bunch Onions, Parsnips, Carrots, Peas, Beans, Wheat, or any other Grain; will drop Mangel Seed in Bunches at different distances, and will be found very useful for persons accustomed to thin seeding, as they will drop 2 or 3 corns (only) in Bunches at 6 inches apart.

Price List and particulars sent post free on application.

BRATTON IRON WORKS, March 27. 1858.

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD: The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; Mann, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROFT, Bury St. Edmunds; DOVE, Swiadon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

THE LEADING SPORTING PERIODICAL.

THE SPORTING REVIEW,

A MONTHLY JOURNAL OF

THE TURF, THE CHASE, AND RURAL SPORTS,

IN ALL THEIR VARIETIES.

Nineteen years ago this work was started for the purpose of giving to the National Sports of this country an organ worthy their importance and popularity. It took the field with a corps of contributors—veterans of experience and skill in the departments to which they attached themselves. For the first time the details of the chase were treated of by masters of hounds; members of the Jockey Club wrote about the Turf; the most eminent of our amateur sailors discussed yachting; the leash—the trigger—all our rural pastimes were dealt with by men of acknowledged authority. Under such auspices its apprenticeship was passed; and the public voice has bestowed on it the character of a "good and faithful servant." In that capacity it discharges the grateful duty of offering its acknowledgements for favours heretofore received; and ventures to hope for a continuance of that success which it will be its earnest effort to endeavour to deserve. No periodical in any branch of literature is more characteristically represented by those who contribute to its pages; no journal is more beautifully embellished—none more carefully constituted with reference to the treatment of popular and seasonable subjects. In the course it has so long run, its race will be continued. It will keep a steady pace—ever make play when fitting opportunity occurs. On the first of every month it will be found at the post, as its trainer brought it out from the commencement of its career, sightly to look at, with plenty of good stuff about it—sound wind and limb—and eager to strain every sinew for the prize of public approbation.

N.B.—Vol. XXXVII., with 13 Steel Engravings, is just out, price 16s. 6d., handsomely bound in cloth, and may be had of every Bookseller in the Kingdom.

Published monthly, price Half-a-Crown, at the "Sporting Review Office", 246, Strand, London; where all communications for the Editor, and Works for Reviews, should be addressed.

To attain the good age of four-score-and-one.

No. 2.

LOVE AND MARRIAGE.

Their Obligations, Happiness, and Disappointments. Love and other Matches. Infertile Unions, their causes, &c., &c.

Too late to grieve when husband and wife,
The die is cast, and is cast for life.

No. 3.

THE CASE BOOK,

A Treatise on

SPERMATORRHŒA,

100 Cases, Causes, Symptoms, and Treatment, Confessions, Cauterization, Galvanism, &c, &c.

Price 1s. each; by Post, 1s. 6d.

To be had of all Booksellers, or direct from the Author's new Residence,

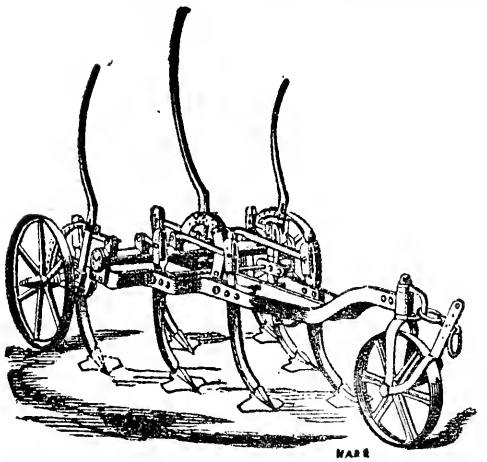
3, GREAT MARLBOROUGH STREET, REGENT STREET,

where all letters are to be addressed.

Dr. C. may be consulted daily from Eleven till Five; Evenings, Seven till Nine. Sundays till One.

No connexion with the old Establishment.

COLEMAN'S PATENT PRIZE CULTIVATOR.



FOR Spring work this Implement is most effectual and economical, thoroughly breaking up and pulverizing the surface without turning it over, and at one-third the cost of ploughing.

Its strength, convenience of management, and ease of draught are unrivalled.

The Public are respectfully reminded that besides a large number of FIRST PRIZES given by the Royal and other principal Societies in the Kingdom, the Royal Agricultural Society of England, at their Triennial Competition, at Chelmsford, awarded Coleman's Cultivator TWO FIRST PRIZES, as the best Cultivator, and the ONLY FIRST PRIZE FOR PARING.

MANUFACTURED BY

COLEMAN & SONS, CHELMSFORD,

Of whom Prices and Testimonials may be obtained post free.

ALSO,

COLEMAN'S PATENT PRIZE EXPANDING HARROWS,

AND

COLEMAN'S IMPROVED HANSON'S PATENT PRIZE POTATO DIGGER,

Of which Implement COLEMAN & SONS are Sole Manufacturing Agents for England and Wales.

TAYLOR'S CONDITION BALLS.

In packets, 6 Balls, 3s.—3 Balls, 1s. 9d.

Unequalled for Worms, Swelled Legs, Grease, Impaired Appetite, Coughs, Colds, Inflamed Eyes, &c. Read the opinions of the following eminent Trainers:—

"For getting horses into condition they are unequalled."
JOHN OSBORNE.

"In my opinion they are invaluable."—JOHN SCOTT.

"Your condition balls are excellent."—SAMUEL ROGERS.

"I have never used so efficient a ball."—JOHN DAWSON

Prepared by **T. TAYLOR,**
Veterinary Surgeon, Burton-on-Trent,
and Sold by all Druggists.

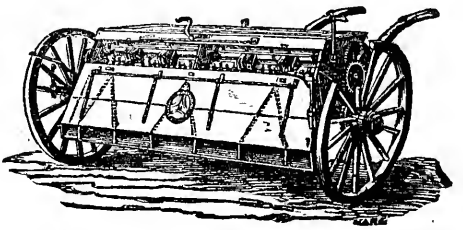
N.B.—Any gentleman using the Balls may consult the proprietor gratuitously, either personally or by letter.

HOLMES AND SONS'
IMPROVED PRIZE MANURE DISTRIBUTOR

WILL Distribute, in a most perfect manner, either broadcast or in rows, from Two to Twenty Bushels per acre of any description of Artificial Manure, whether in a moist or dry condition.

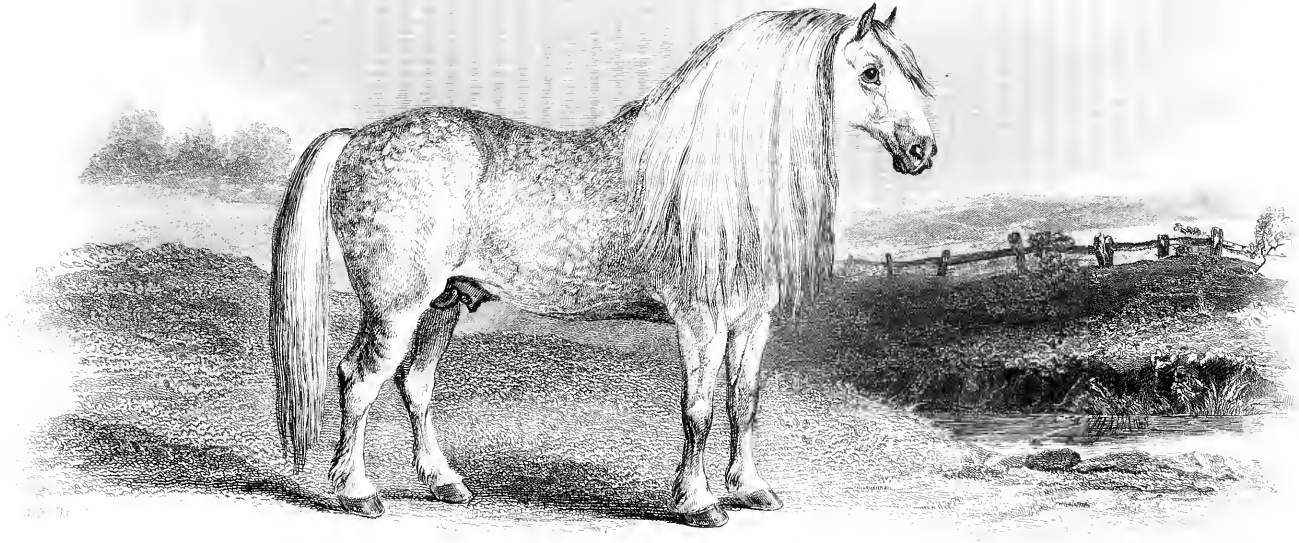
For the above Machines Messrs. HOLMES & SONS have received the following awards:—

AT SALISBURY, 1857..... THE PRIZE
AT SWAFFHAM, 1857 ..... THE PRIZE
AT NEWTON ABBOTT, 1857 ..... THE PRIZE
AT NORWICH, 1856 ..... THE PRIZE
AT CARLISLE, 1855.....the Judges COMMENDED
AT NORWICH, 1854 ..... THE PRIZE
AT BATH, 1854..... THE PRIZE
AT GLOUCESTER....the Judges HIGHLY COMMENDED
AT TAUNTON ..... THE PRIZE
AT THE GREAT EXHIBITION, London..No Competition
AT EXETER ..... THE PRIZE



For Prices and Particulars see ILLUSTRATED CATALOGUES, which will be sent free by post on application to

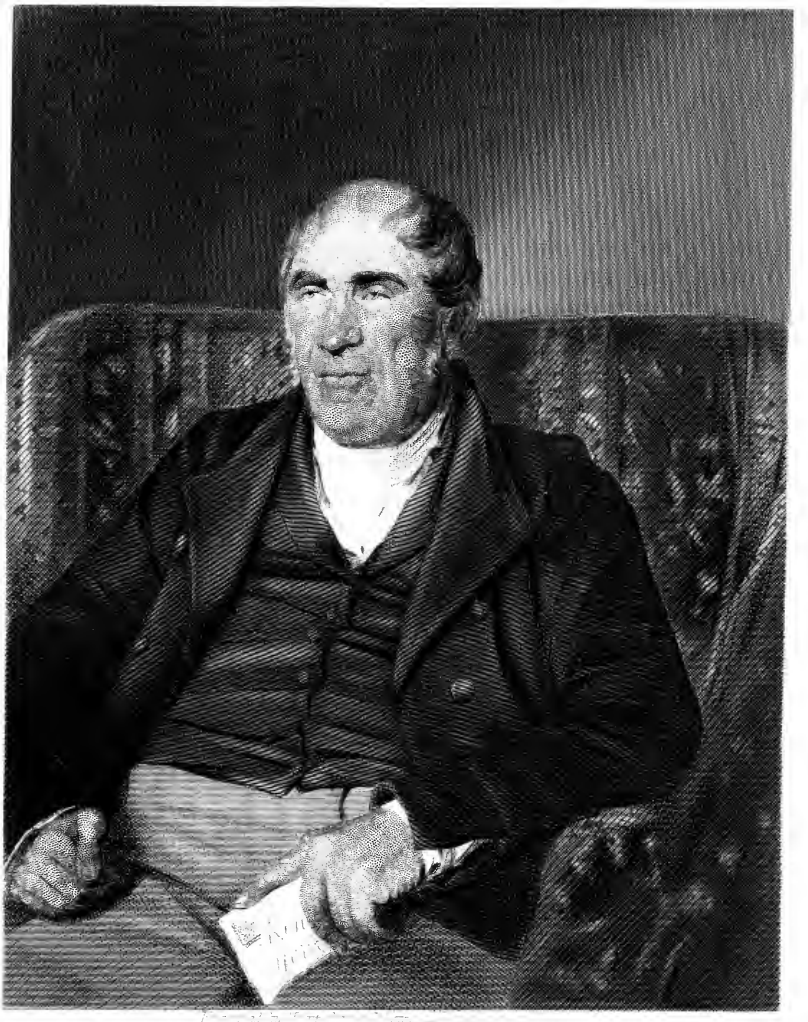
HOLMES AND SONS,
PROSPECT PLACE WORKS, NORWICH.



Matchless,

The Emperor Earl Grosvenor's Property of T. Bevill Hungerford Esqr. Combe Bottom Wilts, Foaled 1834
for which the First Prize of £50 was awarded at the Windsor Meeting of the Royal Society of England, July 1835

London. Published by Rodwell & Martin. 26. Strand. 1836.



THE FARMER'S MAGAZINE.

APRIL, 1858.

PLATE I.

MATCHLESS;

A LINCOLN CART STALLION, THE PROPERTY OF MR. T. B. T. HILDYARD, OF FLINTHAM HALL, NEWARK.

This horse took the first prize of 30 sovs., as the best of all the stallions for agricultural purposes, at the Salisbury Meeting of the Royal Agricultural Society of England. He was entered and shown at Chelmsford the year previous, but drafted out, as it was said, from not being a good mover. His action since then has been wonderfully improved, and certainly at Salisbury there was not a horse in his class at all equal to him in his paces. He stepped as light and lively as a pony. Matchless has, however, other strong recommendations—a splendid head, neck, and shoulders, good old-fashioned quarters, and extraordinary size and substance. His legs, perhaps, are not quite so clean as they might be. But the greatest of all his attractions, to the common run of sight-seers, is a most beautiful mane, fine in quality, and extraordinary for its length. As a show horse it certainly gave him a most imposing appearance; and as a picturesque noble-looking animal, the Suffolks and other mere utilitarians had no chance with him.

Matchless, bred by Mr. Haytoe, of Simperingham Fen, near Folkingham, in 1851, is by the King of the County, out of a Champion mare.

PLATE II.

THE LATE MR. THOMAS KIRBY, OF YORK.

This well-known dealer and sportsman, whose name has for nearly sixty years been connected with English stock, was born at Osbaldwick, near York, in the August of 1770. As he was born and brought up a Catholic, the parish register contains no entry of his birth, and owing to the lapse of years, he has forgotten the exact date. From his very boyhood, "the current of his being set to" horses; and when he was barely 21, he made his first voyage to Russia in charge of a cargo of them, and entered the service of Count Poltrowsky, who had upwards of 100 brood mares in his paddocks. For a long series of years his life consisted in perpetual Russian voyages, sometimes twice in a summer, and occasionally with two ship-loads of horses. His two sons as well as himself had once a very narrow escape from being "washed away in the flood" at St. Petersburgh, when every horse but one in his stable perished, and that was floated into a sort of garret, from whence its exit was of the most precarious kind. So great was the favour with which the Grand Dukes regarded him, that one of them entrusted him to smuggle over some English porter, and he was wont to carry it by a bottle at a time to the palace, when he went ostensibly to chat with them about horses. On one occasion the cork came out with a rush, and if the sentinel had not good-naturedly accepted his explanation, as to its being "frisky beer," he would, as the Grand Duke laughingly told him, have been sent off for a certainty to Siberia, for a season's wholesome meditation on "Barclay and Perkin's entire."

Orville was the first blood horse he ever purchased, 2,000 gs. being the price, and he proved a most successful venture. Lottery, whom he sold for £1,600, to go to France, was another immense favourite. Bourbon also came into his hands from Lord George Cavendish, for 1,100 gs., Brutandorf for 500 gs., Muley Moloch for 1,500 gs., St. Giles for 1,000 gs. (sold to the Americans for just the same price), General Chasse for 2,250 gs., Van Tromp for 2,000 gs., and Lanercost for 3,000 gs. Otterington's price

was 800 gs., and he put him by for a year, and then finding his form was gone, sold him to Lord Jersey and Sir John Shelley, in whose stable he broke his thigh. He also purchased Phœnix from his lordship, and sold him to Mr. Ferguson, of Harker Lodge, near Carlisle; and it was to Lord Jersey that he effected his most successful sale of a yearling by Lottery out of Tambourine for 800 gs. His prices for yearlings seldom exceeded £200, and he generally sold the produce of his five mares at Doncaster. In his hey-day he engaged them pretty deeply, but he was very much sickened of breeding for the turf by the difficulties he encountered in making the vendees pay up the forfeits if the purchases turned out badly, or the contingencies when they won. Hernandez, whom he sold into France with Lanercost, was his last blood-sire purchased.

Mr. Kirby died at York of old age, on Sunday the 28th of last February. Two sons by his first marriage survive him; and about fourteen or fifteen years ago he had married the widow of Mr. Sykes, the well-known trainer. *The Post and the Paddock* will speak further to the adventures of this old English worthy, especially in his dealings with the Emperor of all the Russias.

BARLEY.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

In this the time of barley sowing, at which we are again arrived, we can hardly direct our attention to a more useful agricultural theme. It will be to our advantage in several ways if we spend an April evening in such an enquiry. This will be the more practically useful since there are now several eminent chemists who have lately published the results of their valuable and most laborious investigations on the barley plant. These true friends of their country have examined, not only the produce of barley grown on the same soil for a series of seasons (both unmanured, and also manured with various fertilizers), but they have extended their researches to the varying composition of the seed of barley produced on different soils. It will, happily for the better understanding of our subject, be unnecessary to do more than epitomise the invaluable matter of reports, which ever and anon almost seem intended by their cloudy verbiage to test the farmer's ability in deep diggings.

The reader will, in the paper to which I am about to refer, find abundant materials of the highest practical value. He will ever, in commencing such studies, feel assured that although in the majority of instances the chemist's labours elucidate the correctness of long-established practices; yet in others they shadow forth new objects for the agricultural student's cautious trials; and, in any case, he will not forget the great truth, that although we have long been steadily increasing our knowledge of the habits of barley, yet that there are many questions, with regard to this plant, that yet remain to be explained —mysteries, which when hereafter made clear, will probably give rise to other equally valuable and interesting practical researches.

The growth of barley on the same land for a series of years is an important question, which has for several years past occupied the attention of Messrs. J. B. Lawes and Gilbert "*Jour. Roy. Ag. So.*" vol. xviii, p. 454).

They set apart for these peculiar trials, which commenced in 1852, about five acres of ground at Rothamsted, in Hertfordshire. These were divided into nearly square plots, of about one-fifth of an acre each. The land had grown clover in 1849, wheat in 1850, and barley dressed with sulphate of ammonia in 1851. It was, therefore, as the reporters remark, "in a somewhat exhausted condition, as far as the after-growth of grain was concerned, and it was hence in a suitable state for testing the effects of different manures on the barley crop." In these trials two plots, one at either of the experimental land, were left unmanured, and it is the mean result of these that is given in the subsequent little tables.

The farm-yard dung employed was from the open yard, and not from highly-fed animals. The "mixed alkalies" comprised per acre:

300 lbs. of sulphate of potash.
200 lbs. of sulphate of soda.
100 lbs. of sulphate of magnesia.

The superphosphate of lime was composed per acre of

200 lbs. of calcined bone-dust.
150 lbs. of sulphuric acid (sp. grav. 1.7.

The "mixed minerals" consisted of a mixture of the superphosphate and the "mixed alkalies." The seed, the Chevalier, was always *drilled* at the rate of 2½ bushels per acre in 1852 and 1853, and 7 pecks per acre in 1854-5-6 and '7.

In the following report the produce is given in bushels and pecks. First, then, the produce of the soil entirel yunmanured was,

1852.	1853.	1854.	1855.	1856.	1857.
27 3½	26 0	35 0	33 1	14 1	29 1

Annual average per acre 27 bushels 3 pecks.

The plots with mineral manures only yielded as follows :

	Mixed Alkalies.		Superphosphate of Lime.		Superphosphate and Mixed Alkalies.	
	Bush.	Pecks.	Bush.	Pecks.	Bush.	Peck
1852.....	26	0	28	2	32	3
1853.....	27	2	33	2	35	2
1854.....	36	2	40	2	42	0
1855.....	34	3	36	1	37	0
1856.....	16	2	17	3	19	3
1857.....	32	0	33	1	39	3
Annual average per acre	28	3	31	2	34	2

The plots with nitrogen per acre equal to about 50 lbs. ammonia, with and without direct mineral manures, yielded as follows :

	275 lbs. of Nitrate of Soda.		100 lbs. each of Sulphate and Muriate of Ammonia.	
	Bush.	Pecks.	Bush.	Pecks.
1852.....	0	0	36	3
1853.....	34	1	38	2
1854.....	49	1	47	3
1855.....	50	0	44	2
1856.....	28	2	25	0
1857.....	47	3	38	3
Annual average per acre	42	0	38	2

	100 lbs. each Sulphate and Muriate of Ammonia and "Mixed Alkalies."		100 lbs. each Sulphate and Muriate of Ammonia and Superphosphate of Lime.		100 lbs. each of Sulphate and Muriate of Ammonia Superphosphate & Mixed Alkalies.	
	Bush.	Pecks.	Bush.	Pecks.	Bush.	Pecks.
1852.....	36	0	38	2	40	3
1853.....	36	2	40	0	38	1
1854.....	50	0	60	2	60	2
1855.....	44	2	47	3	48	1
1856.....	28	1	29	0	33	3
1857.....	42	1	56	2	57	1
Annual average per acre	39	2	45	2	46	1

The next question examined by Messrs. Lawes and Gilbert was the effect produced by doubling the amount of nitrogen applied in the last-described series of trials. 100 lbs. per acre of ammonia were therefore employed in the following experiments, and with results given in the next table.

	550 lbs. of Nitrate of Soda.		200 lbs. of Sulphate and Muriate of Ammonia.		2,000 lbs. of Rape-cake.	
	Bush.	Pecks	Bush.	Pecks.	Bush.	Pecks.
1852.....	0	0	44	2	39	0
1853.....	53	1	40	3	39	0
1854.....	37	0	56	2½	60	3
1855.....	49	1	48	0¼	48	2
1856.....	42	0	36	1	36	3
1857.....	58	0	49	3¼	64	0
Annual average per acre	47	3	46	0	48	0

	200 lbs. each Sulphate and Muriate of Ammonia and "Mixed Alkalies.		200 lbs. each Sulphate and Muriate of Ammonia and Superphosphate of Lime.		200 lbs. each of Muriate and Sulphate of Ammonia, Superphosphate and Mixed Alkalies.	
	Bush.	Pecks.	Bush.	Pecks.	Bush.	Pecks.
1852.....	41	3	43	3	45	0
1853.....	41	1	42	1	44	2
1854.....	51	2	63	1	62	3
1855.....	47	1	50	1	49	2
1856.....	25	1	31	2	37	2
1857.....	49	3	66	2	64	3
Annual average per acre	42	3	42	2	50	3

	2000 lbs. of Rape-cake and Mixed Alkalies.		2000 lbs. of Rape-cake and Superphosphate.		2000 lbs. of Rape-cake & Superphosphate, and Mixed Alkalies.	
	Bush.	Pecks.	Bush.	Pecks.	Bush.	Pecks.
1852.....	33	2	36	2	38	0
1853.....	35	1	36	0¾	40	0¾
1854.....	56	2	60	2¾	60	1
1855.....	48	3¾	53	1	51	3
1856.....	32	2½	37	0½	35	1½
1857.....	60	1	62	1¼	62	1
Annual average per acre	44	2	47	2	48	0

In studying these very valuable results, the farmer will not fail to remark the great influence of different *seasons* in modifying the profitable results obtained by different dressings. Our reporters allude to this, when they observe that from the pervading influence of season, by which the produce may be double one year that of another, even with the same set of conditions supplied by the farmer, and which moreover, when unfavourable, the crop most highly manured suffers most, it results that the amount of produce obtained for a given outlay in manure may be only half as much in some seasons as in others. Then, again, it is evident that some of these nitrogenous fertilizers were applied in excessive proportions. The reporters, indeed, observe, "The unmanured, and the only *mineral* manured portions, as a rule, stood up till the time of cutting. The crops with nitrogen equal to 50 lbs. of ammonia per acre were generally more or less laid, as were also those grown by farmyard manaure. Those having nitrogen equal to 100 lbs. or more of ammonia per acre were invariably laid, and in every year excepting in 1857 very much, and injuriously so, the crops being too heavy to bear any moderate amount of rain about or after the time of heading." The effect of these manures in influencing the *period of ripening* is also a material consideration. The "mixed alkalies" it seems, whether used alone, or in admixture with nitrogenous manures, invariably somewhat retarded the ripening. Superphosphate of lime, on the contrary, whether used

alone or in combination with other manures, always promoted early ripening. The effect, Messrs. Lawes and Gilbert add, was most striking. So much so, indeed, that latterly it has been thought desirable to cut the crops at different times, as they came ripe; those dressed with superphosphate of lime, or with farmyard manure, coming to the scythe more than a week earlier than the others. It will presently be seen, that the superphosphate had a marked effect on the *quantity* of produce also, and especially on the tendency to corn.

The general conclusions at which these scientific cultivators arrive, will accord pretty well with those of the farmers who carefully study the above tabular statements, viz., 1. That the use of exclusively mineral manures, and especially those containing phosphoric acid, annually increase the produce of barley. 2. That with barley grown continuously on the same land, nitrogenous manures have a much more striking effect than mineral manures. 3. That by the annual supply of nitrogenous manures alone (nitrate of soda or ammoniacal salts) larger successive crops, both of corn and straw, were in these experiments obtained, than by the annual use of fourteen tons of farmyard manure. 4. That within certain limits, even on the comparatively exhausted soil employed in these experiments, nitrate of soda, ammoniacal salts, and rapecake, all increase the produce of barley approximately in proportion to the amounts of nitrogen they respectively supplied. 5. That the effect of a given amount of nitrogen, if not excessive, is considerably increased by the addition of certain mineral manures, especially those containing phosphates.

The composition of barley (examined chiefly with regard to its nutritive properties) grown on different soils, is an interesting branch of the inquiry that has recently engaged the attention of Professor Anderson (*Trans. High. Soc.*, 1858, *p.* 287). He tells his reader the objects which he chiefly had in view in instituting his experiments, when he observes, that every one who has directed even a limited attention to agricultural chemistry must be familiar with the subdivision of the nutritive principles existing in plants, and required for the food of animals, into two great groups—of albuminous and respiratory principles; the former serving to produce the flesh or muscular fibre of the animals, and the latter being partly consumed in the system in the process of respiration for the purpose of maintaining the animal heat, and partly accumulated as fat to form a reserve against the temporary deprivation of food from want or disease.

A few of the mean results obtained by Dr. Anderson will be found in the succeeding tables:—

The water per cent. in Chevalier barley was, in the specimens examined—

From a gravelly soil (57 lbs. a bushel) ..	14·52
,, a rich, dark loam (56 lbs. do.) ..	14·82
,, a red loam (54 lbs. do.)	14·85
,, a sharp gravel (55½ lbs. do.)	12·76
,, a light sandy soil (55 lbs. do.) ..	14·08

The albuminous compounds in the same specimens of barley were, in that from

A gravelly soil	7 09
A rich dark loam	6 91
A red loam	10·30
A sharp gravel	8·22
A light sandy soil	8·10

The amount per cent. of respiratory compounds in these specimens were, in that from

A gravelly soil	66·43
A rich dark loam	66·57
A red loam	65·75
A sharp gravel	70·57
A light sandy soil	65·15

The proportion per cent. of woody fibre and ash in these were as follows, viz., from

	Fibre.	Ash.
A gravelly soil	8·28	3·68
A rich dark loam	8·57	3·13
A red loam	8·00	1·10
A sharp gravel	5·94	2·51
A light sandy soil	10·28	2·39

From three varieties of common barley he obtained the following results:—In this table, column I. gives the composition of a specimen of barley (weighing 55¼ lbs. per bushel), grown on a thin clay soil; II. that of the same kind of barley (53½ lbs. per bushel) from a sandy soil.

	I.	II.
Water	14·60	12·47
Albuminous compounds	8·97	9·39
Respiratory principles ..	64·14	70·33
Fibre	11·10	5·25
Ash	1·19	2·56

In comparing the value of barley with other grain, as Dr. Anderson concludes, it is obvious that it bears a high nutritive value. In the proportion of albuminous compounds it stands on a level with wheat grown in this country, but naturally from the presence of the husk it is below it in the quantity of respiratory elements; the relative importance of these two groups, however, in a nutritive point of view, has not yet been clearly decided.

These chemical examinations of the composition of barley, and of the effect of various artificial dressings, I repeat, will well repay the farmers for their most careful consideration. The reader should, indeed, ever banish from his mind any lingering suspicion that science has already achieved all the aid that can be rendered to the cultivator of the soil. Let us all rather feel well assured of one certain fact, that many a mystery in the phenomena of vegetation is yet to be explained by the chemical philosopher, that will, perhaps, to the end of time, steadily add to the power and stimulate the efforts of still more enlightened agriculturists than even those of our age.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A WEEKLY COUNCIL was held on Wednesday, the 24th of February: present, Mr. Raymond Barker, Vice-President, in the Chair; Mr. George Raymond Barker; Mr. Bosanquet; Dr. Camps; Mr. T. T. Clark; Mr. Dent, M.P.; Rev. L. Vernon Harcourt; Mr. Fisher Hobbs; Rev. James Linton; Mr. Thomas Scott; Mr. Clark Thornhill; and M. de Trehonnais.

Communications were received: 1. From the Earl of Clarendon, enclosing dispatches from Captain Vansittart of H.M.S. Magicienne, reporting, as the result of a search made during a recent visit to the Gallapagos Islands, that deposits of guano do not exist there in sufficient quantities for practical purposes. 2. From Sir Charles Lyell, a collection of works, received by him from various sources, having a bearing more or less immediate on agricultural science and practice. 3. From M. Andreas von Kiss, of Pesth, desiring the opinion of the Council on a question of exhaustion of land underlet by him to peasants, and of which the Austrian laws took no cognisance. 4. From Mr. Murray (of Albemarle-street), requesting on the part of the Baron von Rosenkrone, of Bergen, information for a committee appointed by the Norwegian Government on the best system of inclosure to be adopted for estates in that country.

The Council adjourned to their monthly meeting on the 3rd of March.

A Monthly Council was held on Wednesday, the 3rd of March: present—Lord Berners, President, in the Chair; Lord Feversham, Lord Portman, Hon. Colonel Wood, Hon. W. G. Cavendish, M.P., Sir Watkin Williams Wynn, Bt., M.P., Sir Chas. Gould Morgan, Bt., Sir Archibald Keppel Macdonald, Bart., Mr. Raymond Barker, Mr. Barnett, Mr. Barthropp, Mr. Brandreth, Mr. Caldwell, Colonel Challoner, Mr. Druce, Mr. Brandreth Gibbs, Mr. Fisher Hobbs, Mr. James Howard, Mr. Hudson (Castleacre), Mr. Jonas, Mr. Lawrence, Mr. Millward, Mr. Paget, M.P., Mr. Pain, Mr. Shuttleworth, Professor Simonds, Mr. Thompson, Mr. Torr, Mr. Vyner, and Mr. Jonas Webb.

Thomas Mills, Esq., of Tolmers, Hertfordshire, was elected a Governor of the Society.

The following new members were elected:—

Body, Richard Barnard, Hyde End, Shirfield, Reading.
Bromley, James, Cockerham, Lancaster.
Buckworth, Theophilus Russell, Cochley-clay Hall, Swaffham, Norfolk.
Cotton, Lt.-Col. Hon. Wellington H. S., Cherry Hill, Malpas.
Davies, Robert Craddock (Banker), 187, Shoreditch, London.
Fanton, Edmund, Hill Farm, Torrington, Devon.
Hagen, Jacob, Roplay, Alresford, Hampshire.
Hall, Thomas, Duke's Oak, Brereton, Congleton.
Hodge, Henry, St. Levan, Penzance, Cornwall.
Lee, Thomas, Brown Edge, Congleton, Cheshire.
Lichfield, Earl of, Shugborough, Staffordshire.
Perry, Sir Thomas Erskine, Bart., West Court, Berkshire.
Simonds, Thomas, Marske, Redcar, Yorkshire.
Seals, Charles William, Leigh-Delamere, Chippenham.
Smith, John, of Sevenhampton, Gloucestershire.
Starmer, Charles, Hogsthorpe Rectory, Alford, Lincolnshire.
Taylor, William, Pool House, Groby, Leicestershire.
Walker, James, Bighrook Hall, Kidlington, Oxon.
Watney, Drniel, Reigate, Surrey.
Wheeler, E., Kyrewood House, Tenbury, Gloucestershire.

FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented the monthly report on the accounts; from which it appeared that the current cash-balance in the hands of the bankers was £612.

JOURNAL.—Mr. Thompson, Chairman of the Journal Committee, reported recommendations: (1.) That Mr. Miles's article in the last Journal on horse-shoeing should be reprinted in a separate form, and sold at 6d. each copy to the public, and at the rate of 2s. 6d. per dozen to members of the Society. (2.) That a bound copy of the Journal should be presented to the library of the Harpenden Laboratory, in acknowledgment of the numerous and valuable contributions made by Mr. Lawes to the Society's Journal, and of the eminent services conferred by him on British Agriculture. On the motion of Mr. Jonas, seconded by Mr. Torr, the discussion of the questions of the amount of salary to be given to a paid editor of the Journal, and the person or persons who should be appointed to discharge the duties of that office, was postponed till the next monthly meeting.

LECTURES ON MILK.—Mr. Raymond Barker, Chairman of the Veterinary Committee, reported that Prof. Simonds, the Veterinary Inspector of the Society, had stated to the committee that his paper for the next Journal, embodying the substance of his lectures delivered before the members on the Anatomy and Physiology of Milk-secretion, was far advanced towards completion, and would be delivered to the Journal Committee by the 15th of next month.

PRIZE ESSAYS. — Numerous essays and reports, competing for the prizes offered this year by the Society, were received.

TRUSTEE.—On the motion of Mr, Fisher Hobbs, seconded by Mr. Milward, Mr. Thompson, of Kirby Hall, and Chairman of the Journal Committee, was unanimously elected one of the trustees of the Society, to supply the vacancy created by the decease of Earl Spencer.

MEMBERS OF COUNCIL.—On the motion of Mr. Milward, seconded by Mr. Torr, Mr. Humberston, of Mollington, and Mayor of Chester, was unanimously elected one of the general Members of Council, to supply the vacancy created by the decease of Mr. Simpson; and on the motion of Mr. Fisher Hobbs, seconded by the Hon. Colonel Hood, Mr. Francis Sherborne, of Bedfont, Middlesex, was elected one of the general Members of Council, to supply the vacancy created by the decease of Mr. Stephen Mills.

CHESTER MEETING.—Lord Portman, Chairman of the General Chester Committee, reported recommendations on the acceptance of Mr. Manning's contract for the works at Chester, and of the Mayor of Chester's arrangements for a dinner for 500 persons in the Music Hall; also on the accommodation of the Judges, and the sale of substantial refreshments at a cheap rate to the labouring classes during the period of the meeting. The Committee also recommended that a Special Committee should be appointed to report, before the selection of the place of meeting for next year, the best arrangements to be made in reference generally to the show-yard works.

On the motion of Mr. Fisher Hobbs, seconded by Mr. Paine, a Special Committee of Show-yard Works was appointed.

Mr. Barnett's suggestion that application should be made for the refusal of extra land, should such be required, for the trial of the steam-cultivators at Chester, was adopted.

Mr. Hudson (of Castleacre) suggested that the general question of the Society's purchasing a suitable pavilion, to be retained as its own property, for the purpose of the great dinner of the Society at its successive country meetings, should be referred to the special committee on show-yard works.

Additional Special Prizes offered by the Chester Local Committee were accepted, and ordered to be included in the Prize-sheets of the Society.

On the motion of Mr. Jonas, seconded by Lord Feversham, Mr. Milward, of Thurgarton Priory, was unanimously elected one of the stewards of the cattle-yard at the country meetings of the Society.

On the motion of Lord Portman, seconded by Lord Feversham, it was decided that the Stewards of the Stock-yard be requested to report to the Council, at a Special Council to be held as soon as possible after the entry of stock, the *number* of Judges required for stock.

METROPOLITAN MEETING.—On the motion of Mr. Brandreth Gibbs, seconded by Mr. Fisher Hobbs, the Council decided that it was desirable that the Society should hold a Metropolitan Show, provided a suitable site could be obtained; and on the motion of Lord Portman, seconded by Lord Feversham, that the Show should not be held until after the year 1860, when the circuit of districts for the country meetings of the Society will have been completed, but in the first year afterwards that might be found practicable. The arrangements connected with this subject were referred to the Metropolitan Show Committee.

DATES OF ENTRY.—Lord Feversham adverted to a misprint in the last part of the *Journal*, which might mislead persons who were not aware of the standing dates at which entries had for many years been made for the shows at the country meetings. It occurred in the last page of the appendix, where, under the head of "Dates of Entry," Live Stock had been misprinted for Implements.

CARD OF MEETINGS, AND ADMISSION OF REPORTERS.—The Council did not adopt Mr. Frere's suggestion for a "Card of Meetings," and they declined to grant Mr. Morton's application, on the behalf of the Proprietors of the *Gardener's Chronicle*, for the admission of Reporters.

STEAM CULTIVATOR.—A lithographed circular addressed to the Council, and requiring special information on the subject of the Society's prize for a Steam Cultivator, was laid on the table; and the Council ordered that Mr. Collinson Hall, Mr. Fowler, Mr. Burrell, and Mr. Williams, by whom it was signed, should be referred to the printed rules for trial, to which the Council would adhere.

The Council adjourned to their weekly meeting, on March 10.

A WEEKLY COUNCIL was held on Wednesday, the 10th of March; present: Mr. RAYMOND BARKER, V. P. (in the chair), Mr. Dod, M.P., Mr. Gatty, Mr. Brandreth Gibbs, Rev. L. Vernon Harcourt, Mr. Fisher Hobbs, Mr. Allen Ransome, Mr. Thomas Scott, Mr. P. Simpson, Professor Simonds, and Mr. George Wood.

Mr. Bailey Denton made an application in reference to his intended draining operations abroad. — Mr. Eddleston alleged his discovery of a cure for Pleuro-pneumonia and Potato disease, and his willingness to communicate it to the Council under certain terms of remuneration.—Mr. Spencer Trower, of Stansteadbury, presented a fœtal foal, 46 days in embryo, taken from a mare 21 years old (a specimen which Professor Simonds considered to be interesting as showing the early development of the fœtus).—The Committee of Council on Education presented copies of an Almanac prepared by the Science and Art department. The Rt. Hon. T. F. Kennedy presented a copy of Mr. Spence's work on the practical consideration of the Coal, Smoke, and Sewage questions.

Adjourned to March 17.

A WEEKLY COUNCIL was held on the 17th of March; present, Lord BERNERS (President) in the chair; Mr. Alcock, M.P., Mr. Fuller Baines, Mr. Raymond Barker, Mr. Body, Mr. Caird, M.P., Mr. Fisher Hobbs, Mr. Holland, M.P., Mr. Langston, M.P., Mr. Majendie, Mr. T. Scott, Mr. Vyner, Mr. Burch Western, and Mr. Sutton Western, M.P.

Communications were received—1. From Mr. Stallard, of Redmarley, Gloucestershire, suggesting a prize to be offered by the Society, for the best-constructed moveable shade for sheep during the hot months of the year, especially on the red warm sandy soils, for the purpose not only of comfort to the animals themselves, but of preventing their damaging the under part of fences, and their losing flesh during the period of hot weather. The President had found simple awnings constructed of four upright poles, open at the sides, but covered at the top with faggots or brushwood, answer the purpose very well. 2. From Mr. Alcock, M.P., suggesting that the Society should offer a prize of £100 for the largest amount in value of agricultural produce (serving as food for man or beast), in one year, from a single acre of land, provided a fair profit be shown by the cultivator; the application for the prize to be accompanied by a detailed account of the cost, value of the crop, and mode of cultivation, and notice given to the Secretary by any person intending to compete.—These communications were referred to the Journal Committee.

Adjourned to March 24.

NOVEL APPLICATION OF HORSE-POWER.—The *Montrose Standard* directs attention to the "performance of a new method of applying horse-power to drive machinery, which Major Rennie Tailyour, of Borrowfield, has introduced at his steading at Newmanswalls. The apparatus, which is very simple in its design, differs entirely from the mode hitherto in use. Instead of moving round in a circle, and drawing the end of a lever attached to an upright shaft, the horse remains stationary, fastened in a stall, and the flooring on which he stands passes backwards under him, as he appears to step forward. The flooring consists of a series of stout boards, lying across the stall, and resting on and made fast to two endless chains stretched round a couple of drums, one at the head and the other at the foot of the stall, thus forming, as it were, a firm but flexible belt, on the upper surface of which, as on a moveable floor, the horse stands. The drum at the head of the stall being somewhat more elevated than at the foot, this moveable floor is slightly inclined; and the weight of the horse causes it to descend towards the lower drum, carrying the horse backward along with it. As, however, the halter by which he is tied in the stall obliges the horse to maintain his position, he is compelled to step forward continuously as the floor recedes under him; and the revolution of the drums thus produced drives whatever machinery it is intended to propel. At Newmanswalls it is successfully applied to driving a thrashing machine, a chaff-cutter, and a machine for bruising oats. No driving or watching is required; and we were informed that a horse might work at this species of treadmill without distress or fatigue for eight hours." [The practice is common throughout the United States and Canada. In fact, the wood at every minor railway station is sawn in this manner.]

THE AGRICULTURE OF FRANCE.

At the height of what might have been so delicate a crisis, it becomes us to be especially careful as to what we say of our neighbours. With the notoriety of the Fleet-street Forum by way of a warning, we should be more than usually nice in our parts of speech. There should not be a phrase to quarrel with, or even a word to cavil at. It is difficult, then, to imagine an orator vehement in his denunciation of what is going on over the other side of the Channel—how the higher classes in France are bought and sold with honours—how the monied men are rotten to the core—how the improvements in Paris are made at an unfair expense to the country—how those who would do good have no power—and so on. And yet it has been our fate to hear lately a great deal in this strain; not, however, at a gin-and-water parliament in the City, nor from the over-excited aspirant of a debating club. On the contrary, no less august a body than the Society of Arts gave its countenance to the occasion. Further than this, the reader has only to associate the staid decorum of its discussion-room with the wild Irishman or headlong patriot who rejoiced in so unexpected an opportunity of having his "fling."

This would make the offence complete; but luckily the Society is saved the more serious part of the charge. It is no wild Irishman who talks like this; no ferocious Cuffey bound on re-organizing, not merely his own country, but all the world over. For the very reverse, take a plump, really contented-looking gentleman, who speaks with an accent so decidedly foreign that it is difficult to follow him—who announces himself as a landed proprieter in Normandy—and who, in fact, is a Frenchman, just giving his opinion on the political economy of his own country. The Society of Arts is inexpressibly relieved, and the "reading" proceeds with far more equanimity than had Brian Boru or some home-bred Hampden been in possession of the chair.

Strangely enough, the text-word of this address was Agriculture. Now if there is one thing more than another that we Englishmen should be inclined to regard with a feeling of satisfaction, it is the effort France has lately been making in this way. If there be any one cause that has induced more than another to kindly intercommunication between the two countries, it has assuredly been this desire to improve the cultivation of France. The international shows are still fresh upon our recollections. The manner in which the English were received, and the way in which they endeavoured to return the compliment—the individual courtesies of the Emperor to men distinguished amongst us in the pursuit—His evident sympathy with the art—the prices he gives for stock—the example he is setting in farming—when we come to reflect on all these recent manifestations, one might suppose a glance over the agriculture of France would surely by this time turn to the sunny side of the picture.

Stranger even still, perhaps, there was no one, who by his antecedents stood better recommended to read a paper on French farming than the introducer of this subject. One of the first points in his favour was that he was well known to English farmers; another, that he had a natural taste for the occupation; and, a third, that he is now pursuing it in France. Monsieur Trehonnais was just the man to have made a practical comparison between the cultivation of the two countries. With his intimate knowledge of either, it should have been his peculiar province to have directed the excellence of ours to the wants of his own system. Unfortunately he did not dwell enough upon this very essential matter. The first part of a long address was devoted to the agriculture of France, traced as far as three hundred years back, and of course dependent upon the authorities of those times. The second section, which touched more upon the present condition of the country, partook rather of an essay upon political economy than one directly referring to agriculure. In fact, the subject itself was little more than incidentally touched on, and what was said of it was tinged with something very like, utter despondency.

According to Monsieur Trehonnais, the farming of France is as bad as it possibly can be—worse than it was three hundred years ago. This would appear to be mainly attributable to two grand causes—want of labour, and want of capital. France, be it remembered, is essentially a military nation; and the continual drain of able-bodied men must of course tell upon the cultivation of the country. The two arts never yet flourished together. Monsieur Trehonnais further attributes this scarcity to what he considers the present injudicious centralization in towns. The embellishments of Paris, for example, are made at the expense of agriculture. The 300,000 additional inhabitants of a few years chiefly consist of mechanics and labourers removed from the country. The want of capital naturally follows. He speaks of the amount of treasure lavished on the city—the disproportionate expenditure for public works in Paris compared with the whole of France. The chief cause of this want of means for improving the land—at least, the one generally received as such amongst us—he will not admit. He believes the evil influence consequent on the division of property to be more apparent than real. At the same time he allows that share for share does take place: the daughters receiving an equivalent in money, and the land remaining with the son. Under such a system, it is almost impossible to imagine anything but the soil being continually mortgaged with these "equivalents," and left without a franc for its own improvement. In this country no man now does so badly as the one who just hangs on to his own bit of land. With the small occupier, either owner or tenant, no great progress can be attained; and France is overrun with these small holdings. Monsieur Trehonnais thinks it only right they should be thus limited in accordance with the means of the people. He must remember, however, that nothing can be done without capital, while the greatest bar to its use is the perpetuation of these little properties. Men in such a position can never command it. If we needed any illustration of this, we have only to look to Ireland as it was, and as it is. It is hard to suppose that the agriculture of France can be materially advanced without some more decided action of the law of primogeniture.

Monsieur Trehonnais himself unintentionally supports this view of the case. He will have everything depend upon individual exertion—a sound conclusion enough, although he rather over-impresses it. It strikes but harshly to hear the recent efforts of the Emperor characterized as worse than useless:—"But, I may be asked, has the French Government done nothing to revive agriculture? There is a Minister of Agriculture; there is a large and influential staff of agricultural inspectors; there are innumerable Government

model farms, agricultural colleges, breeding establishments, where the best English cattle are kept; there are shows, both local and general; there have even been some called universal and international. We have heard of a vote of £4,000,000 sterling for drainage; there is a bank of *crédit foncier;* very large sums of money are spent from the consolidated funds and from local resources, in liberal prizes and encouragement. Surely all these must have exerted a considerable influence upon French agriculture, and given an extraordinary impetus to its progress."

Surely, at any rate, say his hearers, the effort is a noble one; and if such encouragement does not effect something, it ought to. But what says Monsieur? He answers us with a very terrible simile:—

"We have all heard of—and some of my audience, perhaps, have seen—a strange and somewhat awful experiment performed by means of a galvanic pile upon a corpse. A wire is put in communication with the spinal marrow, and life, movement, and action are restored to the muscles; the corpse will stand erect, open its eyes, move its arms and legs; its livid lips will quiver as if they were going to speak, and to all appearances death has been conquered, and the corpse lives: but only interrupt the mysterious current from the pile, and the lustre of the eyes will vanish, the arm will fall inert, the jaw will hang, the eyelids will close, and the ghastly corpse will fall to the ground, once more a helpless mass, on the verge of decomposition. In like manner the action of the French Government props up a show of activity, a show of vitality, in the French agricultural interest; but it exists only on the surface. Who are those who exhibit at the shows? They are only a few amateur fancy farmers; and the specimens they exhibit very often constitute the totality of the stock they have on their farm, and are by no means a sample of the agriculture of their districts. The farmers, with very few exceptions, are not only not exhibitors, but not even visitors. The schools have been productive of very little good. As farms, they have been lamentable failures, and the peasants point to them as instances of the folly of modern ideas; in fact they do not pay, and as model farms they ought to pay."

And so on. But Monsieur Trehonnais should bear in mind that a whole people do not take to a business like this on the instant. It was some years, even, before our own great agricultural show came to be appreciated, and for many it had to bear up against all kinds of abuse and ridicule. We really believe that, whatever the Emperor may have done for France in other ways, his laudable attempts to advance the agriculture of the country have been both judicious and effective. We may—indeed we must, wait for such a result; but it will come nevertheless.

We could wish to have concurred more fully with the tone of this paper. Somehow or other, however, it was scarcely suited to an English taste, and there was not a speaker who followed Monsieur Trehonnais but that dissented from his deductions and opinions. As these were chiefly friends of his own, this expression of feeling is the more remarkable. The last few years have given many the opportunity of seeing something of French agriculture, as well as of what the Emperor is doing for it.

THE GAME LAWS.

INJURIOUS EFFECTS OF UNDUE PRESERVATION OF GAME ON OUR HOME SUPPLIES.

At a recent meeting of the Milborne St. Andrew Farmers' Club, Mr. Richards opened a discussion on this subject. Mr. H. Fookes in the chair.

Mr. Richards proceeded—Although the circumstance of my bringing before you the subject for our discussion this evening originated from a passing joke, yet permit me to say that I consider it a very grave and important subject, and one which deserves our most serious consideration. I say then, gentlemen, it is an important subject—and why? My answer is, because it involves the question of a most serious loss to the country at large, and a perfectly ruinous one to individuals. You who know what quantities of agricultural produce are annually destroyed by rabbits and hares, will not be surprised to hear me say that my opinion is, it would be possible to show that the preservation of game lessens our home produce to nearly the extent of our importations. I would not have you understand me to say that food to this amount is eaten by rabbits and hares, but that our produce is lessened in one way and another to this extent. I would now proceed to show in what way the preservation of rabbits, hares, and game generally may be said to lessen our produce; to consider the effect, direct and indirect, to individuals, and to the public; and to suggest a means by which an equal amount of sport would be afforded, without the objectionable consequences which now exist in many cases. First, then, in what way is agricultural produce so lessened by the preservation of game? And here I may be met with the objection that rabbits are not game, and therefore it is unfair to consider the damage done by them under this head. To this I would answer that, in preserving game, the increase of rabbits is almost a certain consequence; and although they may not, strictly speaking, constitute game, yet to kill them is an offence punishable under the game laws, and an act which, on the part of a tenant, would displease a game-preserving landlord. It may be said—"Why, it will only take so much to keep a rabbit, and so much a hare, and therefore the consumption cannot be so great." But you do not need to be told by me that it is a case which admits of no such rule of calculation. Could farmers by any means confine these animals, cause them to feed where they would choose, and make them eat their way clean as they go, then it may be possible to arrive at something like a correct estimate of the value of keep. But this you know to be impossible. What, then, are the facts? Take first the swede crop, which, as you are aware, is raised at a heavy outlay, and which, probably, the grower intends as a provision for his sheep in the spring, and on which he may be solely dependent for food at that period. What, then, are his disappointment, inconvenience, and loss, when he finds that instead of twenty tons per acre which he had on his land in November, he has, in the month of March, not more than ten? and, probably, of the ten tons lost, not more than two or three have been eaten, or even less than this, as you well know that when turnips are bitten they decay, and, for one ton actually consumed, five, or even more, may rot in the ground. And now, gentlemen, how shall we estimate the loss arising from such destruction? The answer of some may be, "Why, you lose so many tons of swedes, the market value of which is so much." That I admit is your first *direct* loss; but, where a flock of sheep is kept which have to be fed on that farm, who shall say what the loss may be on that flock? And this is only a mere beginning of injuries; for, if you have but one-half the amount of keep to feed on your land, you leave on that land only one-half the quantity of manure which would have been left had you fed your entire crop. I need scarcely ask you what will be the effect on your next crop? Where hares and rabbits have eaten swedes they will also visit barley; and, as by the loss of so large a portion of your turnip crop you have been unable to leave much manure, your corn crop grows sparingly, and the consequence is that it requires a large breadth to furnish food for these nightly visitors; and at harvest you may make up your mind to be content with, it may be, less than half the crop that you would have had but for the ravages of these vermin. I do not intend to attempt

to trace these effects to their end, but I cannot stop yet. I would next inquire, what are the results of a deficient corn crop? Not only are you deprived of your fair returns from this branch of your produce, but the amount of straw is also lessened; consequently you have not the quantity to convert into manure to return to your land again, which you ought to have, and your future crops must suffer. Some may say one good arises from a light crop of barley, which is, that your clover and grasses do better. In some measure this may be true; but, remember, before you reap much benefit from this crop you have to psss through a winter; and I would inquire what is your experience of the effect of incessant close feeding through a winter on a clover crop? I venture to assert that no crop, whether sainfoin, red clover, or any other description of clover, is proof against the continual feeding of a large stock of hares and rabbits, and that consequently the destruction of your clover crop is as certain as that of your corn crop. Your land, in its turn, comes to wheat, and this being an autumn-sown crop gives a long period, at a time when food is scarce, for game to feed on it. And here, too, as you well know, if too closely fed, its destruction is certain; and if not really killed, is so checked by repeated bleeding, that it will not grow until a late period in the spring; and the consequence is that you get scarcely any corn in your straw, and, what little you have, of most inferior quality. Rabbits, as you are aware, feed on and keep down a certain breadth, whereby the injury is perceptible at a glance; whereas hares cut roads in all directions through corn, leaving those roads completely covered with ears of corn; and therefore, unless a close inspection is made, it would a'most pass unobserved, but although the damage is less apparent, it is, I believe, greater in amount. You are aware, gentlemen, that all I undertook to do was merely to launch the subject for you, in order that the various members may have an opportunity to express their opinions, and I think what I have said is sufficient for that purpose, as well as to show that the actual destruction by hares and rabbits is very considerable. But it is not to this alone that I attribute the deficiency on our home produce. Consider the many thousands of acres of useful land at this time made available for nothing but for the preservation of game. Look, again, at the additional thousands which, although not actually incumbered and forming preserves, are but very imperfectly cultivated from their contiguity to game preserves. Consider, then, the increased amount which may be grown were all these lands well cultivated and none of the produce consumed, and say whether you do not think that England may be made to feed her own population? Next, then, as to the effects of this destruction. To the individual who suffers the direct loss it is most ruinous. No consideration of rent can compensate for it, and I believe it would not be difficult to trace to this cause the ruin of many a man of capital. There is a maxim, not unfrequently quoted, that "The man who makes two blades grow where only one grew heretofore, is a benefactor to his country." May it not with equal truth be said that he who imposes an obstacle to the full development of the resources of our soil is an enemy to his country? It appears to me that there can be no more genuine source of national wealth than the produce of our soil, particularly as it furnishes the chief necessaries of life; and whether the food for our population be raised on our own soil, or whether a large proportion be purchased in foreign countries, at a cost of many millions sterling per annum, is a question of no small amount to the country at large. I think the farmers of England may say—"Allow us fair scope for the application of our capital, our skill, and our energies, and you shall have little occasion to go to foreign shores for human food." Are we, then, to curtail the rights of our aristocracy to their sports? I would be the last man to make such a proposition, and I am quite sure there are none among you who would not be pleased to show your landlord and his friends a fair amount of sport; and I think this could be done without the present system of game preserving, and at a much less cost to the landlord. I should hope there is enough of principle among the agriculturists of the present day, to entitle them to a little confidence from the owners; and I would say, make every tenant keeper over his own farm; give him at least an unrestricted right to kill rabbits and hares, and you shall find an equal, if not an increased amount of legitimate and fair sport; for every farmer would feel a pride in showing his landlord and his friends good sport; he would take an interest in the preservation of game, whilst he would have it in his power to protect himself from the injuries of the rabbits and hares. He would overlook a little damage done by hares rather than not have enough of them to afford a fair amount of sport. We all know the difference between a voluntary and a compulsory loss; and whilst a man would bear cheerfully with the one, he would feel the other to be a gross injustice. Give a man an interest in the game, and he at once feels responsible for its preservation, and becomes as jealous over it as over his own stock. He would discountenance poaching, and thereby prevent breaches of the law, which sometimes lead to more serious crime. No man has the same influence with the labourer as the master, and no man so likely to know his habits and character; and who can doubt that when a man is suffering severe losses by game, and dares not defend himself against them, nor in any degree participate in the sport of destroying it, he will sometimes shut his eyes to acts of poaching, and that, too, without feeling that he is really countenancing a breach of the law? Gentlemen, I feel I have occupied a full share of your time, although I have but feebly and imperfectly discharged the duty I undertook. Having been bred a practical farmer, my education and early associations have not fitted me either for an author or an orator; but of this you may rest assured, that the little experience I have gained by my intercourse with the world is ever at your service, for I feel that we are linked together by bonds of no common order, our object being not our individual benefit, but the common good of all. When I have heard the remarks of the members present, and should I find their views accord with mine, I shall be prepared to submit a resolution to the meeting.

Mr. DOWDEN said, although he agreed with Mr. Richards' arguments, he was happy to say he did not suffer from an excess of the game nuisance at the present time. The evil had been put down to a great extent, as he was at liberty to kill hares, rabbits, &c., on his farm. He, however, remembered the time when he could have shot one hundred and fifty couple of rabbits in one day. This species of game he regarded as more destructive than any other; as, wherever they assembled in numbers, they poisoned the soil, and ruined everything that came after them.

The CHAIRMAN (Mr. H. Fookes) could not agree with Mr. Richards as to the loss inflicted by the preservation of game in England. No doubt, however, rabbits did a great deal of mischief to the crops and herbage. He considered that the farmer was a better preserver of game than the gamekeeper; for the privilege to shoot gave him as much interest in preserving it as any other man. He had not much confidence in gamekeepers generally, though there might be some respectable men amongst them.

A conversation took place respecting the means adopted to snare rabbits by traps, so as not to hazard the lives of other game. The Chairman expressed an opinion that this *sine qua non* was altogether delusive, and said that the same trap which caught rabbits could snare all other game.

Mr. RICHARDS, in reply, said he thought more members of the club would have expressed their opinions upon the subject. With regard to the Chairman's comment on his remark as to the quantity of produce consumed in England by game, he would reply that the damage done in this county was less than in any other. In other counties the damage was infinitely greater; the game being more strictly preserved. In many instances also it was deemed disrespectful for a tenant to make complaint to his landlord against a gamekeeper, and the consequence was that there were no greater poachers anywhere than gamekeepers. Mr. Richards then submitted the following resolution to the approval of the club: Resolved—"That it is the opinion of this club, that the manner in which game is preserved in some districts is most objectionable, inasmuch as it impedes the advancement of agriculture, subjects the tenant farmer to serious losses and inconvenience, and in many cases is the cause of disagreement and ill-feeling between landlord and tenant. And whilst we do not wish a repeal of the game laws, or in any way to infringe the rights of property, we consider that if tenants were allowed the right of sporting over their own farms, to the extent of killing hares and rabbits, they would insure to the landlord an equal amount of sport to that which he now enjoys, and in most cases the chief cause of complaint would be removed."

The CHAIRMAN said he fully coincided with the resolution, and on being put to the meeting, it was carried unanimously.

Mr. ROBT. FOOKES moved, and Mr. DALE seconded, a vote of thanks to Mr. Richards.

MEETING OF HOP-PLANTERS FOR THE ABOLITION OF THE DUTY.

On Friday, March 18, a large and highly influential meeting of hop-planters and others was held at the Sussex Hotel, Tunbridge Wells, for the purpose of promoting the repeal of the excise duty on hops. There were between 300 and 400 present.

On the motion of Mr. Moses Body, chairman of the committee, Mr. Rutley (Wrotham) was called to preside.

The CHAIRMAN said it would be his first duty to inform them that the meeting had been convened by bills drawn up by the committee appointed at the Robertsbridge meeting. As to the object the society had in view, he could only repeat the advice which he gave the planters at the Robertsbridge meeting, namely, that if they wished to secure the public attention and interest in their cause, they must proceed boldly upon a broad principle, and persevere consistently in one course. It was a matter of very great congratulation that so many persons had assembled. He took the circumstauce as unmistakable evidence of the wide-spread depression—he might say distress, which they saw around them, and which had aroused them to public action. If he understood the objects of the meeting aright, it was not, however, merely to assert their distress and proclaim their losses, but to state publicly that they believed themselves to be unjustly subjected to a heavy and burthensome duty, and to devise the best possible means to get rid of it—to assert that the hop duty in its apportionment was unjust and unequal as a tax. There was no other tax like it upon any industrious class whatever in the country. He was well aware, however, and he did not wish to ignore it, that there were even hop-growers who would prefer that the duty should remain as it was, rather than that it should be repealed. That desire arose from the circumstance that those growers had many peculiar advantages of soil and situation, and did not feel the pressure to the extent that the majority of growers now experienced. That was the reason why they found those persons were in a position to pay the duty. But he could not consider the mere fact of one particular set of planters in a certain district desiring to maintain the duty was any argument in its favour; indeed, he should rather say no further proof was necessary that the duty was unjust and unequal, because one set of men were anxious for its continuance, while the majority were oppressed by it, and wished for its repeal. The persons who were anxious that things should remain as they were, asserted that hop-growing always had been, and always would be, a lottery; that it was a great speculation, and that all who entered into its cultivation ought to be prepared to meet its contingencies. They had been told that if they were patient the market would rise again, and they would have more years of profit. He well knew that they had had such years, and that they might occur again, even under the present system. But upon what circumstances would that improvement arise? It would be the very consequence of their present ruin, and the evils which had been already inflicted by the duty. Planters had been driven to grub their hops, and cease from their cultivation altogether, and it was at such a cost and sacrifice that any temporary prosperity would be secured. The attendance around him persuaded him that they were no longer inclined to submit to this unjust imposition.

Mr. MOSES BODY then rose to propose the first resolution, which was, "That the excise duty on hops is most oppressive to the grower, unequal in its pressure, most uncertain in the amount of revenue derived from it, and most unjust, hops being the only agricultural produce subject to taxation in the hands of the grower, upon which the duty is levied irrespective both of the value of the article and the cost of production." He did not stand before them as an advocate of free trade in hops, for he did not know that they could grow hops under that principle. Some told them that the duty was a tax upon the consumer, and that it did not press much upon the grower; but they well knew that they had very recently been selling hops at 17s., 18s., and 20s. per cwt., and he should like to know who had paid the duty on those, if the grower had not. It was very clear it was not paid by the consumer (Hear, hear). It was also said that they could grub their hops if they found the cultivation of them did not pay, and thus relieve themselves of the burden. He had no doubt they all knew, being practical men, that there was some difficulty in that matter; they were aware that they had a large amount of labour upon their hands. He, for one, had lately, and perhaps most of the large planters had, grubbed a portion of their hops; but they could not get rid of the labouring population. That hung upon them in some way or other, and they must be maintained; and he had himself set on many extra hands, because many were literally starving. In fact, he had more hands than he knew how to employ; but in the country districts it was not so easy to be disengaged from them, and that was one reason why it was so difficult to get rid of their plantations. If a man took a farm of some 200 or 300 acres, of which 20 were planted with hops, a large proportion of the valuation was taken upon the hop ground, perhaps £20 or £30 an acre. Therefore a man's capital became locked up in that way; and if he grubbed his hops, he by that means destroyed his property. Another reason why they could not grub their hops so easily as was supposed was that it was always after a heavy crop that they wanted to grub, because there was a larger produce than they required; in fact, they could not regulate the supply. With malt it was just the reverse—they made as much as was wanted. But they could not manage the hops in that way, as they did not know what produce there would be; but, after all, so far as grubbing was concerned, the greatest drawback was the duty itself. A man had got perhaps ten or twenty acres, prices were very low, and the tax something like £20 per acre, if he grew a ton an acre. He grubbed his hops and covered the land with corn, and probably got a profit of £3 or £4 an acre, but the succeeding crop had to pay the tax upon the previous year's produce (Hear, hear); therefore, if a man had £300 or £400 duty to pay upon twenty acres of hops, it ruined him. He must not, therefore, grub. Those were strong reasons, he thought, why they should get rid of the duty; but he had no doubt they all knew the matter as well as himself. He had been a grower for the last twenty-five years, and during late years at a considerable expense. He had found it a most unprofitable speculation; and he was persuaded that, unless they got rid of the excise duty, they could not continue to grow hops in these counties. If that were so, he would ask, "What would become of the labouring population in the hop districts?" He was himself at a loss to know.

Mr. PARKER (Tunbridge) seconded the resolution, which was carried unanimously.

Mr. JOHN SIMES rose to propose the second resolution, which was as follows: "That it is the duty as well as the interest of all hop growers and others resident in or connected with the hop districts to take all the means in their power to procure the immediate abolition of this unjust tax." He was in the habit of making valuations, and he had been struck at the number of farms that had lately been stripped for payment of the hop duty. He was also in the habit of receiving rents, and had therefore had opportunities of noticing the difficulties with which those payments were met, and in many cases could not be met in consequence of the tenants having had to meet the hop duty. He was well aware that there was a difference of opinion upon the subject, and he was very sorry that it was so. It was only a few, however, who objected to the present movement, and they were only those who were seeking to retain a monopoly: they were trying to drive the industrious classes out of the market. If they made a fair calculation they would find that in the Weald of Kent and Sussex they had been paying something like 35 or 40 per cent. more than the Mid-Kent people. There lay the question. Let the Kent people, who were so bigotted in their opinions, and who tried all they could to drive others out of the market, have 40 per cent. put upon them. How would the question appear then, he should like to know; he was sure that they would soon be

rowing in one boat, and all would go hand and heart together in the endeavours to get the tax removed. All they wanted was a fair stand up fight. At present he was quite satisfied they were labouring under free-trade prices, and had at the same time a heavy duty hanging over them, and they need not expect to get anything during the next two years in the shape of new profit. The duty consumed them more than free trade. If any of them had anything to say on the subject he hoped they would do it manfully, and let the public know that they were unanimous. They must give a "long pull, a strong pull, and a pull altogether," until the tax was laid under their feet.

Mr. J. KENWARD (Uckfield) rose to second the resolution. It might not, he said, be deemed prudent on his part to do so, as he had been on the opposition side, but he now found that he had been travelling on the wrong road. He made it his business, however, to attend that day, and render his assistance in endeavouring to get rid of the tax.

Mr. J. WIBLEY (Sevenoaks) said he was a grower of high-priced hops, but he heartily agreed with the two resolutions that had been proposed. He was an old free-trader, and did not fear the importation of foreign hops in the least. He thought the high-priced men in Mid Kent and East Kent would benefit more from free-trade than any part of Sussex or the Weald of Kent; the consumption would increase according as hops were lowered in price. Why should they be ruined in their prosperity year after year, merely to be protected £1 6s. from foreign hops? it was a complete bugbear; it was all very well when hops were eight guineas a cwt.

Mr. BODY begged distinctly to state that the society they had formed was not established in any respect as a free-trade society, upon free-trade principles. They had nothing whatever to do with free-trade. He had made those few observations from fear that some wrong impression might go abroad upon the matter.

Mr. WHIBLEY said he did not think anyone would volunteer to go to Government for a repeal of the Customs' duty; they did not ask for the repeal of that duty, but the question was one of a free trade character.

Mr. THIRKELL said he was a large grower in the Weald of Kent. He trusted they would wake out of their sleep, and make vigorous exertions to obtain the repeal of so unjust a tax.

The resolution having been unanimously carried,

MR. NASH (Rochester) said he had been called upon to move—"That a society having been formed to promote the repeal of the duty upon hops, this meeting pledges itself to take the most active measures to support that society in the attainment of its object." He stood before them as a Kent planter of more than twenty years' experience; he had grown hops in the hill district as good as most men grow, at least they had fetched as good a price—and he must say that he did not wish to see any gentleman grub his hops. He had been to Somerset-house and made extracts from some of the books. He would have them clearly to understand that there were altogether three duties—the old duty, the new duty, and the 5 per cent., and he would tell them what had been the amount of each for every year. In 1711 the old duty of 1d. in the lb. was put on; 1778 the 1d. per lb. was continued, and the 5 per cent. was put on; in 1780, 10 per cent. was added; in 1783, 15 per cent. was added; and in 1786, 1½d. and 2-20ths was added; in 1801 it was 2½d.; in 1806, it was reduced to 2d.; in 1840, when all exciseable articles were taxed, 5 per cent. was laid on; nearly all the latter tax had been removed, the only articles on which it remained being paper, malt, and hops: he believed that was a fact. He had taken the three years 1855-6-7, and he would give them the returns for those years, as he had taken them from the House of Commons. The amount of the new duty and war tax in 1855 was £294,643 10s., and the additional 5 per cent. on that was £34,661 10s. 4¼d, making £329,305 0s. 4¼d. The planters had been called upon to pay that above the 1d. per lb. duty. Those were startling items, but correct ones. In 1856, the new duty amounted to £197,869 2s. 4¾d.; and the additional 5 per cent., £23,267 1s. 3½d.; making £221,136 3s. 8d. In 1857, the new duty was £168,999 13s. 10¾d., and the additional 5 per cent. being £19,879 15s. 6¼d, making £188,879 9s. 5d. The total of the last three years, of what he would say they were called upon to pay in excess of the 1d. per lb. was £739,320 13s. 5¼d. If such a statement as that, of which he vouched for the truth, would not make them active, he did not know what would. Allusion had been made to the customs duty, which he did not think they had any right to have; for what had they to be afraid of, when he told them that the customs duty upon hops sent into this country year before last, and charged at 45s. per cwt., only amounted to £22,546? It did not amount to £10,000 of their duty, and were they willing to pay £417,526 to keep that £10,000. He recommended they should call a meeting in every parish, and get up subscriptions in every possible way. He for one would pledge himself to get subscribers to the amount of £50. Many people he was aware agreed with Mr. Dodson, M.P., that members of parliament did not know very much about the subject of the hop duty; but he begged to assure them that from many interviews he had had with those gentlemen they did know something of the subject and were taking a lively interest in their welfare. He was happy to tell them that he had received many promises from members that they would vote for the repeal (renewed cheers). He hoped therefore the planters of Sussex would set a first-rate example, and they might depend upon it that others would follow them, for they were all beginning to feel the pressure and would be glad to work alike. He had gone the length and breadth of the three kingdoms; and knew the general feelings of the country. If the planters would help themselves, everybody else was ready to assist them.

MR. BARCLAY seconded the resolution. He observed that let him go where he might, and the subject of the hop duty was mentioned, people who knew nothing about it frequently said, "What did it signify to the planters? They got their prices for the hops, which included the duty, or they would not grow them." That was a point to which they should turn their particular attention. The growers knew and felt that they paid the duty, and that in many instances they never got back again any sum of money which at all represented it. There were too many of them held hops of 1855, and there was very little doubt that a large proportion of them would never be sold, and the growers would therefore not see the duty, to say nothing of the expense to which they had been put. What they had to do principally was to show, as nearly as they could, the situation in which they were with regard to the duty. They were called upon to pay it whether the hops were sold or not, and under any circumstances; if the hops were spoiled the duty must be paid out of their pockets. But the business in which they were at present engaged was as important a matter as any hop-grower could undertake, for they ought to get rid of the excise duty if they could by any possibility; for he was sure there were very few farmers who did not feel that heavier than any other payment. It was asked for in large sums, and at a time when they had sold the article for which it was claimed. If they did not care for the duty, and he believed there were a few in that situation, he would say, don't subscribe; but if they did, subscriptions would enable them to get rid of it.

The resolution having been carried unanimously,

MR. BARCLAY proposed a vote of thanks to the chairman.

The CHAIRMAN acknowledged the compliment, and the meeting separated.—(Abridged from the *Sussex Express*.)

LANGUAGE OF INSECTS.—I have frequently observed two ants, meeting on their path across a gravel walk, one going from and the other returning to the nest. They will stop, touch each other's antennæ, and appear to hold a conversation; and I could almost fancy that one was communicating to the other the best place for foraging. This Dr. Franklin thought they have the power of doing, from the following circumstances: Upon discovering a number of ants regaling themselves with some treacle in one of his cupboards, he put them to the rout, and then suspended the pot of treacle by a string from the ceiling. He imagined he had put the whole army to flight, but was surprised to see a single ant quit the pot, climb up the string, cross the ceiling, and regain its nest. In less than half an hour several of his companions sallied forth, traversed the ceiling, and reached the depository, which they constantly re-visited until the whole of its contents were consumed.—*Jesse's Gleanings in Natural History.*

COMPOSITION OF FISH MANURE AND SOME SORTS OF ANIMAL REFUSE.

Although the importance of all sorts of animal matter as a manure has long been familiar, and has been frequently insisted on, both by science and practice, the immense quantity of such refuse has hitherto become very partially available. The main difficulty which has stood in the way of their profitable application has been the want of a good process by which they can be converted into a portable form. The enormous quantities of fish refuse annually produced in Newfoundland, and even on some parts of our own coasts, has been frequently pointed out as a source from which agriculture might derive valuable assistance. Considerable interest was excited, some time since, by the proposal of various methods by which the desirable object of rendering fish offal portable might be attained, and very important results were anticipated from them. As yet, these anticipations have not been fulfilled, material difficulties having been encountered in carrying most of the processes into operation on the large scale, some of the plans proposed having proved too expensive in practice, while others are so obviously unpractical that no one has been found willing to invest capital in carrying them out. The error, in most cases, has lain in the employment of expensive machinery, which the conditions under which such a manufacture must be carried out may be said to preclude. It is probable that the quantity of fish offal to be obtained at any one spot will not generally be very large, and will be chiefly collected at one period of the year, so that the machinery would require to be sufficient to work up with rapidity the whole of the offal produced, and would lie idle during the rest of the year. It is in some such way that most of the plans have hitherto failed; but I have recently analyzed a sample made by a patent procees, which is said to be simple and inexpensive; and should the manufacture yield, on the large scale, a material of uniform quality, and equal to that I have examined, it will undoubtedly prove a very important addition to the list of ammoniacal manures. The manure was in the form of a yellowish powder, in grains about the size of fine oatmeal, remarkably uniform in appearance, very dry, and almost devoid of smell. Its composition was:—

Water, ...	8.00
Fatty matters, . . .	7.20
Nitrogenous organic matters,	71.46
Pnosphate of lime, . .	8.70
Alkaline salts, . . .	3.80
Silica, ...	0.84
	100.00
Nitrogen, ...	11.25
Equal to ammonia, . .	13.68
Phosphoric acid in the alkaline salts equal to 1.41 phosphate of lime	0.65

There can be no doubt that, if fish manure, of equally good quality, can be produced, a large demand for it will soon be created. It is, in fact, a very valuable manure, and its price may be estimated very readily, according to the mode employed for Peruvian guano, by taking the commercial value of each of its important manurial constituents as derived from other sources. The values usually adopted by chemists have been at the rate of ¾d. per lb. for phosphate, and 6d. per lb. for ammonia; or, expressed in tons, £6 for the former, and £56 per ton for the latter. Upon this plan, and taking all the phosphates under one category, we estimate the value of 100 tons of the fish manure as follows:—

13.68 of ammonia at £56 . . .	£766
10.11 of phosphate of lime at £6 . .	60
Value of 100 tons . . .	£826

or almost exactly £8 5s. per ton; and this will probably be its average value. At the present time, however, owing to the high price of bones and ammonia, its value would considerably exceed this. Sulphate of ammonia is now selling at £16 per ton, and at this price *ammonia* is worth £64, and phosphate of lime can scarcely be reckoned under £10 per ton, bones at present selling as high as £6, or even £6 10s. If these data be taken for calculation, the value of the fish manure comes to be—

13.68 of ammonia at £64 . . .	£875
10.11 of phosphate of lime at £10 .	100
Value of 100 tons . . .	£975

or £9 15s. per ton. In connexion with this subject, it may be well to observe, that there are many sources of animal matter which must, at the present moment, be entirely wasted, although they might, with a little management, be turned to good account. Of these, perhaps, the most prominent is the blood, and other offal of slaughter-houses, in our small towns and villages. In the larger towns, the blood is collected, although not very carefully, and finds its way to certain classes of manufactories in which it is employed; but in country places it is, for the most part, allowed to escape. It would be a matter of some interest to ascertain the annual value of the blood and offal thus lost, which is undoubtedly very large, and a great part of which might easily be saved by a very small expenditure of care. Such, however, is the carelessness of the workmen employed in slaughter-houses, that I have been informed, that, even in the large towns, it is with difficulty that they can be persuaded to save the blood, although its price is really considerable. Fresh blood contains nitrogen, equal to about 3 per cent. of ammonia, and is worth about 2d. per gallon, or nearly £2 per ton; and any far-

mer, living near a small town, might advantageously contract to take the whole of the blood at this price. There are many other sources of animal matters which will at once occur, available for manures. Of these, we may particularise the refuse of glue and oil-boiling works, which yield, annually, a considerable quantity of nitrogeous offal; and the two analyses of seal and glue refuse which follow will show that, even when they are prepared without much care, they may become useful manures:—

	Seal Refuse.	Glue Refuse.
Ash	36.81	53.18
Organic matter	41.85	38.60
Water	21.34	8.22
	100.00	100.00
Ammonia	2.24	2.00

The large quantity of ash in these cases is due to the admixture of earthy matters, for the purpose of drying up and rendering portable the animal matter; and, though this has not been done in the most suitable manner, the value of the manure is about five times as great as that of good farmyard manure.—PROFESSOR ANDERSON, in the Transactions of the Highland Society..

GRINDING FEED.

Experimental farmers have long urged the importance, and even necessity, of chopping or grinding hay, as well as other food, for cattle and horses. The lazy drones have had a hearty laugh over the idea, and called it "Book Farming."

Now the theory of chopping and grinding food is based on a principle which lies at the foundation of animal physiology. Rest is essential to the accumulation of muscle, as well as fat. If we wish to increase an animal in flesh or fat, we do not work him.

Now a cow wants one-thirtieth of her own weight in hay a day, to keep her in good order; and we may thus calculate the amount of labour required to masticate the food, and fit it for the stomach. The labour of chopping or grinding twenty-five pounds of dry hay a day, is no small item. This excessive labour is performed by one set of muscles—the jaws; but, by sympathy, affects all the other muscles; causes the blood to circulate quicker, the breath faster, the consumption of food greater; and still the growth of the animal is retarded.

If a machine was invented to *grind* hay, the ground article would approximate, in value, to *unground* oats, in producing fat and muscle. Chopping hay and stalks is valuable just in proportion as it approximates to grinding, and relieves the animal of the labour of grinding it. An animal fed on ground or minced food may perform an amount of labour equal to grinding it fit for digestion, and fat as fast as another which does not labour, but grinds its own food.

Prematurely grey whiskers and beard, while the hair is still black, show the relative amount of labour performed by the jaws and the head.

LIME, AND ITS CHEMICAL CHANGES.

Lime is not, as it was once supposed, an *element*, but consists of the metal calcium united with the gas oxygen, and is properly an oxide of calcium, just as potash, soda, and magnesia are oxides of potassium, sodium, magnesium. It is never found pure in nature, except occasionally in the craters of volcanoes, but is usually united with carbonic acid, for which it has a strong attraction. In thia state it is neutral, and insoluble in pure water. When limestone or any other form of carbonate of lime is exposed to a sufficiently high temperature with access of air or moisture, the carbonic acid gas is driven off, and the lime which remains is called *quick* or *caustic*, from its strong alkaline re-action. When such lime is plunged into water for a short time, or water is poured upon it, heat is evolved, the lime swells, cracks, gives off much watery vapour, and finally falls to a powder. This powder or slaked lime is a *hydrate* of lime, water being chemically combined with it. In this state it is still caustic, though somewhat milder than when fresh from the kiln.

The rise of temperature is so great when large heaps of good lime are suddenly slaked, as to enflame gunpowder and scorch wood; it certainly exceeds, according to Pelletier, 500°; and when the operation is performed in a dark place, light is also evolved. All sorts of imaginary causes have been assigned to account for these phenomena. They are referable, however, to a very simple and universal law. All substances during their change from a gaseous to a liquid, or from a liquid to a solid state, evolve heat, and *vice versa*. The intense cold produced by liquefying ice or snow by admixture with salt is a familiar instance of the latter; and the heat evolved in solidifying carbonic acid under intense cold and pressure is sometimes dangerous evidence of the former—the expansion of air consequent on the sudden liberation of heat from the carbonic acid in the moment of congelation not unfrequently shattering the vessel to atoms.

Lime in slaking will absorb one-fourth its weight of water; but the slaked lime is not more moist than before. The water unquestionably, therefore, is chemically combined with the lime, and becomes *solidified*; and it is simply owing to this solidification of the water that heat is evolved.

Caustic lime has a strong affinity for water and carbonic acid. When kept in a dry place it gradually slakes, cracking, splitting, and crumbling to powder with the evolution of heat —which, however, is not so perceptible on account of the length of time during which the process is extended—just as though it had been slaked by pouring on water. In this case the lime has obtained from the atmosphere the 25 per cent. of water it needs to slake it. There is this difference, however, between *air-slaked* lime and that which is water-slaked: the former is slaked precisely as the latter, by the absorption of water, but it also absorbs carbonic acid from the air, and instead of being simply a *hydrate* of lime as when water-slaked, it is a definite compound of hydrate and carbonate of lime, 42.6 per cent. of the former, and 57.4 of the latter. *Air-slaked* lime, therefore, is far from being so caustic as water-slaked, upwards of one-half of it being reconverted into the same chemical state as it was in before burning.

After the lime has absorbed sufficient water and is completely fallen to pieces, carbonic acid is absorbed much less rapidly, especially in damp situations. In fact, though there is a constant tendency in lime to return to the state of carbonate in which it existed previous to burning, yet, by mere exposure to the air, it does not attain this state in any assignable time.

In some walls 600 years old the lime has been found to have absorbed only one-fourth of the carbonic acid necessary to convert the whole into carbonate; in others, built by the Romans 1800 years ago, the proportion absorbed has not exceeded *three-fourths* of the quantity contained in natural limestone.

When slaked in the ordinary way, by the application of water, lime falls to pieces without the absorption of but little if any carbonic acid; but when slaked and exposed to the air, the absorption of carbonic acid is at first very rapid, but it gradually becomes very slow, and probably the same definite compound of hydrate and carbonate of lime is formed as in the case of air-slaked lime.

The original limestone, or any other form of carbonate of lime, then, is perfectly mild. By driving off the carbonic acid by heat we get lime which is very caustic: by slaking this with water we get a less caustic substance—hydrate of lime: by allowing it to air-slake we get a still less caustic compound —a definite compound of hydrate and carbonate of lime: and by exposing it to the air for a sufficient length of time we ultimately get the whole recouverted again into its original mild form—carbonate of lime.

THE OLD AND NEW SCHOOL.

The true criterion of farm-management will be found in the result; and when we see different systems producing nearly similar results, it is worth inquiry how they have been brought about. We generally have two classes of farmers in every district—the first, as he is called by his modern neighbours, "one of the old school"; the second, as he is termed by the other, "one of the new school"—both titles expressive of their modes of proceeding.

As regards the first of these, we have one who acts methodically: he adopts a system, and pursues it, without in any way diverging from it. His expenses are reduced to a certain standard, and from year to year are almost without variation in amount. His returns differ only as seasons or prices dictate, the proportions in acreable quantity being always the same; and whether he adopts the four, five, or six-course shifts of husbandry, his pursuing it for years together, without the slightest alteration, enables him annually to estimate the result, so far as external operating causes will permit him to do so; while the varying success or failure, in a single year, will necessarily depend upon circumstances which he cannot control. Upon a farm of 400 acres of arable we shall find regularly 100 acres in wheat, 100 in barley and oats, 100 peas, beans, or clover, and 100 acres green or fallow crops—such as rye, vetches, turnips, mangolds, or rape. By pursuing this uniform system the quantum of labour requisite for the cultivation of the farm is invariably the same; and, that being the case, all other proportions of expenditure necessarily follow; so that year by year the variation will scarcely be appreciated, excepting, as already stated, when it has arisen from circumstances altogether beyond his power. The prices may vary, but the measure will remain the same: thus rent, labour, and seed-corn continue in the same proportion; parochial charges, tradesmen's bills, and tithe rent-charge fluctuating only to a limited extent, but never materially affecting the general result; and housekeeping and personal expenses rarely vary more than from five to ten per cent. Thus each year has its fixed expenditure; the farm thus striking, as it were, its own annual balance of profit or loss as it proceeds.

On the other hand, we find the experimental farmer adopting every theory as it arises: he pursues no stated system. In some years his various descriptions of grain crops far exceed those of others; he has learnt to autumn-fallow, and his principal exertion, if it may be termed such, is to farm as little without it as he may be able. He produces roots rather as successional than principal crops, adopts autumnal fallowing as his system, purchases manures *ad libitum*, produces grain crops in successive seasons on the same land, abolishes every previous rule of rotation, and consequently in some seasons his acreable quantities of grain will far exceed those of others. His expenditure also in labour varies greatly, but is generally materially increasing in amount, both as regards horse and manual. His outlay in implements, cattle, oil cake, and cattle food is so large, he becomes subject, to a great extent, to the fluctuations that attend trade. His returns are doubtless increased; but his outlay is in like ratio; and what perhaps is worst of all, the current year does not exhibit its profit and loss sufficiently clear to demonstrate to himself what is the actual profit or loss, or how things are really progressing.

It is not our intention to deprecate improvements or high-farming; but our object is to exhibit to farmers that a methodical system, when carried out, is most advisable, and generally most conducive to success; for just so far as a farmer strikes out a new path, he becomes also subject to greater risks, and which, without corresponding talent and adequate capital, is not likely to lead to any beneficial results. Whatever is done well continuously carries its own reward; but an indiscriminate application of capital, without a corresponding increase of skill and perseverance, will be almost certain to lead to disasters; and we therefore caution experimental and ardent cultivators to pause as they proceed; for although we are quite aware that a large return of any particular description of produce can be sometimes obtained, still there are certain limitations, to which, upon an average, it must be reduced; and even then much will depend upon the skill used in arriving at such an end. We have lately read of a very large expenditure about to be made upon an estate, very far exceeding the value of the fee. We have before heard of this in other quarters; and whether it be as example or experimental farms that they come before our notice, it is not sufficient to inform us that the production has been doubled, if the investment and expenses have been doubled also. The clear profits, after all, must become the test by which the speculation has been carried on. It is an old adage, but a true one, that we see the ships only that arrive in port; those which have gone down are forgotten. The successful agriculturists have mostly been found amongst the class first named; and when we consider the operating causes producing such results, we feel we shall be only anticipating the conclusions of our readers that this must ever be so.

THE CLASS OF PLANTS MOST LIKELY TO ENRICH THE SOIL.

SIR,—There is too general an idea abroad among farmers, especially our moderns, that he who buys the most manure, artificial or otherwise, is, and must be, the best farmer. I happen to think differently, and consider that he who gets the greatest return for the capital expended displays the most wisdom. The sorts and varieties of plants grown have, I think, much to do with profit, with the same management. It is a well-received opinion that plants absorb a considerable amount of material from the air, as carbon, &c. Now, if the leaf of the plant, as philosophers tell us, be the medium of conveyance of matter existing in the air, what is the natural inference but that we ought to grow those plants which present the greatest surface to its influence? Take, for instance, the turnip plant—how is it that with the same appliances we get one quarter of barley more per acre (with a certainty) after a crop of globe turnips than where swedes have been grown? The thing is clear to our mind; and as matter cannot spring out of nothing, so no more can a good or more superior crop come without a cause. I have grown most varieties of the turnip for many years, and have always found that sort to give the best return which had the greatest top or most leaf. Some years ago there was, and with some even now is, great anxiety displayed to get that kind of turnip which had the largest bulb and the very small top. The after-corn returns disappointed that choice as a natural consequence, because the nitrogenous medium had been curtailed. We should aim at a bulb as large as possible, and a top as nearly resembling the cabbage as may be.

It does not follow, as some may suppose, that an increase of top tends to injure the quality of the bulb; far otherwise. The large leaf supplies the bulb with the flesh-forming material it could not otherwise obtain; and in winter affords to that bulb a natural protection pleasing to behold. What farmer at all observant, on a cold frosty morning, has not seen the providential adaptation of the leaf to the bulb when that leaf has succumbed to the cold? I am not recommending the globe variety, or the swede, but that in either case the leaf should be as large as possible.

As regards the manurial properties of the leaf, I consider them always worth as much, in the early winter, to plough in as to eat. The same reasoning holds good with other plants. A field of rape, because of its immense leaf, stands first as an improver. Last year the writer had a field sown with it, and at the same time seeded down with mixed grasses, and it kept and fatted ten sheep to the acre during the summer. The practical farmer will know what the high after-condition of that will be; and this spring it will afford, from the stems left, fine early food for sheep.

On all inferior worn-out lands nothing can equal the fertilizing power of the rape plant. Let the land intended be well autumn-cleaned, ploughed early in the winter, manured and limed in early spring (not ploughed after keeping both on the surface), and sown with rape, about 7lbs. to the acre; and at the same time seeded with mixed grass seeds for two years after grazing; and no soil, I think, will refuse the benefit. As regards the cereal crops, the same rule holds good; the more flaggy it is, as it is called, the less exhausting the crop.

The variety called Scotch oat stands pre-eminent in this respect: in itself quite a favourite with the miller, from the oily nature of the grain, and consequently high mealing qualities; and the straw so good, that it stands next to hay as fodder, full of flag, and easily consumed by cattle; while the American, Poland, Zealand, short white oats, and similar varieties with clean flinty straw, draw strongly on the soil, and the straw is but of little value.

Barley is appreciated because of the little injury it does to the soil, and is more flaggy than wheat. Wheat, when the crop has fine clear straw, is, to every observant farmer, more exhausting than the mildewed field. Beans, peas, and other leguminous plants, are considered fertilizers from the same cause—that the quantity of leaf-surface presented absorbs carbonaceous and nitrogenous matter from the air; and consequently they gain more than they lose. And if the principle be true, that in the process of combustion the same elements return to the air which had been absorbed from it by the plants or otherwise, the effort of the farmer (when confirmed by practice) should be to produce and cultivate those plants the agency of which would profit without the direct aid of manures, in many cases too costly.

The subject is one of importance to the farmer, and these few hints may lead abler hands to investigate it, and see whether science and practice in this respect agree; then, perhaps, we may not object to a drum-headed-cabbage turniptop, and kettle-bottom-sized. S. G.

Normanton, Alfreton, March 16, 1858.

FIARS' PRICES.

We give below a table of the fiara' prices of grain as struck up to Saturday, for purposes of comparison between counties. From the various methods taken in striking the fiars, it cannot be expected that a near approach to equality can be reached. Some counties take the purchasers and others take the sellers of grain, and one or two add to or deduct from the prices after the averages are ascertained. In looking over the various prices, the fiars of oats, beans, and meal appear to run nearly on a par and with no great difference in value, but the wheat and barley prices vary in a surprising degree. The general average of wheat appears to be £2 1s. 2d. per qr.; and while Dumfries is 7s. 4d. above this, Edinburgh is 4s. 3d. under it—in fact Edinburgh is within 8d. of being the lowest wheat fiars' price; and, in like manner, take the price struck for barley in Wigtown, 33s. 10d., and the Edinburgh averages of the three prices struck, 24s. 11d.—making Edinburgh for barley 8s. 11d. below Wigtown. The first class barley average in Edinburgh is stated at 27s. 3d.; the second, 25s.; the third, 22s. 6d.; while during same period the average of all kinds sold in Edinburgh stock market would reach 28s., or thereby, while first-class barley would certainly be above 29s. 6d. to 30s. of average:—

—*Scotsman.*

THE SPANISH OR MERINO BREED OF SHEEP.

[COMMUNICATED BY LORD WILLIAM LENNOX.]

Prejudice founded on system, devoid of experience, is the greatest and most insuperable bar to improvement in every art and science. It was through false impressions thus imbibed, that although the fine-woolled sheep of Spain had been long ago found to retain their valuable qualities in countries still more unfavourable to them than Great Britain; such as Sweden, Denmark, Saxony, Prussia, and Holland: yet it was not until seventy years ago that George III., guided by his own good sense and the most patriotic motives, gave orders for the importation of Merino sheep, for the improvement of British wool. In 1791 his Majesty received a small stock of four rams and thirty-six ewes from the Negrette flock, and about ten years after another importation of two thousand from the Paular flock, deemed the best in Spain, of which only fourteen hundred ewes and a hundred rams survived the voyage and the seasoning in this country. Prejudice for awhile opposed the improvement of fine-woolled sheep as an innovation. The breeders fancied that the quality of the fleece depended on the climate, soil, and pasturage of their native country, and that the Spanish sheep would not thrive in our island, or would decline, and only yield wool of an inferior quality; in fact, they maintained the erroneous opinion that the British sheep sent to Spain would, by the same advantages, become equal to those of the latter country; and that the Merinos imported to England would soon become similar to our own breeds, even without any crossing or intermixture. It required all the influence of the King, the late Duke of Bedford, Lord Somerville, Dr. Parry, Mr. Tollet, and various others of the most enlightened gentlemen and most scientific breeders, to combat this dangerous opposition; and it was only by proof the most irrefragable that it began to decline; and it is now admitted that Spanish sheep, with nothing more than the common care administered to our own flocks, will not only maintain their natural superiority, but will confer the same qualities to other breeds, if due precaution is taken to preserve the strain in its purity. The chief and only obstacle that remained, was the article of expense to the small farmer or grazier. The woolstaplers and the butchers also raised some objection to the newly-naturalized animals; but it having been ascertained that the wool of the Anglo-Merino is equal, if not superior, to that imported from Spain, and that the flesh, as an article of food, is also of a superior quality, their clamours have also subsided, and reason has taken the place of unfounded declamation.

The advantage of the Anglo-Merino strain being thus acknowledged, the only thing that remained was to consider the best method of bringing the improvement into general practice. It had been ascertained that not less than four removes from a pure Merino would ensure all that was required; and the breeder therefore, having purchased the best Merino ram, persevered in breeding in-and-in to the fourth remove, when he found himself the possessor of a pure breed, without any danger of retrograding, proper care being taken to prevent commixture with any less pure strain. The result was most satisfactory, for from actual experiments made by Dr. Parry the Merino-Ryeland carried more than three times the value of wool on the same living weight of carcase than its Ryeland ancestor did; almost four times as much as the Southdown and Lincoln, and nearly five times and a-half as much as the New Leicester. It appeared moreover, from Lord Somerville's trials on the Ryeland and Merino-Ryeland breeds, that the value of the wool on the latter is as five to two of the former—an increase which more than compensated for any additional expense or trouble. To those who are interested upon the subject of Spanish sheep, we recommend a perusal of a very clever treatise by Monsieur Lasteyrie, an intelligent Frenchman, which has been translated into English. He defended the system, which brought George III. under the lash of ridicule of Peter Pindar, viz., that of feeding sheep on horse chestnuts. Monsieur Lasteyrie thus writes: "In Saxony great care is taken to collect the horse chestnuts, which are regarded as a wholesome aliment, and a specific against the rot. These are given to the sheep in autumn, when the green food ceases. The chestnuts are cut into pieces, which it would be dangerous to omit, as they might otherwise stick in the throat of the animal, and cause its death. Sheep, as well as cattle, refuse at first to eat this food; but, when accustomed to it, they seek it with avidity, and even like to eat the prickly husk in which the nut is enveloped."

One of the first toasts at sheep-shearing feasts used to be—

> "The glorious memory of George the Third,
> Who first to Britain Spanish sheep transferred."

In the Consort of our Gracious Sovereign we have one who possesses the good sense, sound judgment, and patriotic spirit of her royal grandfather, and who, as a practical farmer, will exert his influence to improve the breed of cattle, pigs, and sheep, by never rejecting without a trial any rational hint of improvement.

ORDER UPON THE FARM.

It has been very correctly said that order or method is the secret of success of many wealthy men of the mercantile class. The above being true, the rule is equally applicable to the farming classes. What we mean by order is, "a place for everything, and everything in its place." By everything, we mean all that a farmer uses in his business. A farmer should see that every rail and board about his premises is in its proper place; that his fences are in condition to prevent the entrance or exit of his own or other people's cattle without his consent. Every one who neglects this neglects his peace of mind, as well as subjects himself to losses that must be repaired by means that could have been otherwise profitably employed.

I have known cultivators of the soil to succeed well in maturing crops, but by neglecting to keep their fences in order, lose the most valuable part of their labours. But I am glad to state that such cases are not frequent in these times. In the next place, the farmer should not allow his cattle that are used in the farm-work to be scattered indiscriminately over his fields, as much time is lost in getting them to their places, and as "time is money," it should be economised as much as possible. He should be careful to have his harness all in using trim, his working cattle near his harness house: then but a few minutes are required to prepare for his day's ploughing and hauling. His implements, of every description, should be kept near his dwelling, that no time be lost in repairing those things that are out of order. Many persons will say that they cannot find time to do all these things. Stop, dear reader; I know you can, because whenever you see a rail missing from your fence, go and put it back immediately, for then is the right time. In case the rail should be destroyed, appropriate the first idle one you come to; if you should have no idle ones, lose no time in procuring some; for if you do not, nine chances in ten you lose more by neglect than if you stop the plough long enough to make them. Whenever you have done using a plough, hoe, rake, hay fork, thresher, reaper, or anything else, take it immediately to the barn—make this an invariable rule, and let all your men know it: the result will be, that when anything is wanted, the person sent for it will know where to find it. I would have every farmer have some of the most necessary tools used in making and repairing his implements of husbandry, for I know every one who is able to own a farm is able to have such things. The rainy season, in which much could be done in the way of making and repairing, is always lost to most farmers, because they have not the implements of manufacture. During such times he might put all his farming utensils in excellent working order; whereas if it is neglected until fair weather, he has scarcely had it done before another rainy season overtakes him: thus, all fair weather, in which he might have ploughed, passes in repairing. To conclude—Farmers, preserve order in everything, and peace, prosperity, and health will accompany you through life.—*Watchman and Reflector.*

THE DIFFERENT BREEDS OF STOCK.

In the infinity of agricultural topics we are now continually discussing, it is curious to notice how rarely we touch on our different breeds of stock. We of course learn the individual excellence of animals from their positions in the show-yard, and occasionally test the merits of a herd by the prices it will bring at the hammer. There is many a man, too, ready and anxious enough to cry up the sort he himself is interested in; but what we want is, that these opinions should be brought into rather more direct comparison. At this very moment there are two or three beasts that make "the best butcher's meat"—the Scot, the Welsh runt, and the Devon. Then the Short-horn is good to feed, but bad to milk; or, on the other hand, he is as useful for one purpose as the other. The very essence of discussion is difference of opinion, and here we should be sure of it. Still we scarcely remember a single occasion on which the object of a meeting has been to consider which are the best kinds of stock. The Highland Society certainly gave an evening some two years ago to the assumed advantages of crossing; and the London Club has two subjects on its card this season on the management of stock. We repeat, however, that the great question itself is seldom or ever put:—Which is the best beast—a Hereford, a Short-horn, or a Devon? Which is the best sheep—a Southdown, a Leicester, or a Cotswold? And which the best horse—a Suffolk, a Clydesdale, or a Lincoln? We do not say it would be possible to pass any very definite resolution in answer to such queries; but nevertheless a great deal of interesting information might be obtained by such a means. At present we would almost seem to agree with Mr. Mechi in regarding our flocks and our beeves merely as necessary nuisances, and so saying little or nothing about them.

A comparatively young association in the North of Scotland has within these few weeks taken the bull by the horns. Mr. Home, the Chairman of the Stirling Farmers' Club, has opened a discussion "On the various Breeds of Cattle." In doing so, he naturally dwelt chiefly on such kinds as he himself and his brother-members were best acquainted with:—"I speak of our well-known black cattle, which, although reared in many parts of our country, are yet shown to greatest advantage and perfection in the county I have named, Argyle. It cannot fail to be observed that good specimens of our black cattle possess almost every point that the breeders of cattle of England and elsewhere are endeavouring to produce. We all know their fineness of hide, straightness of legs, length and breadth of hind-quarters, fine development of breast and chest; and we know that that breed which is most highly esteemed, so far as we can compare a large beast with a small one, is almost exactly the same. The quality of their flesh is considered wholly unsurpassed, there being a fine degree of marble mixture of fatty matter which cannot be surpassed. It is well known that the nobility and gentry of England get up our Scotch kyloes as their finest beef. They are in a half-wild state, and must be fed fat upon grass, for the Highland ox takes as long to get accustomed with a byre as another to be fed fully fat in it. As milkers they do not excel in quantity; but the quality is shown by the manner in which they suckle their calves."

This is more than commonly well put, and certainly so far our Northern friends have no fault to find with their champion. He proceeds to what he terms "a peculiar breed"; but a better known one amongst us, that reared in Galloway, Aberdeen, Kincardine, and Angus. "How that breed has come to be what it is, forms a difficult question—whether they be a species of the West Highlander somewhat changed, and having lost their horns, I don't know; but there is a peculiarity regarding them. Those in Galloway are larger and thinner from the hook to the tail, though not so broad as others; while those in Aberdeen are broader over the back. It may be mentioned that the latter county has at this time the honour and glory of supplying what in the London market is called pure Scots, and they carry the highest price for beef in the London market. In regard to their milking properties, I have the authority of Mr. M'Combie, of Tillyfour, that they are excellent milkers; and he scouted the idea of an Ayrshire being compared with them in Aberdeenshire. I may mention that his place is by no means a garden of Eden, being without shelter, on the top of a hill; and yet there are to be seen some of the most magnificent animals you can conceive. Long may the Aberdeen folks have the credit of producing the best Scots for the London market."

So that even in Scotland there are two or three varieties which make "the best London beef." We have, then, the Fife breed, "few in number," and according to another speaker, "coarse in quality, and not to be recommended." The discussion from this point assumed a more general tone, as it touched upon the merits of two sorts of which we have all more or less some experience. These were the Ayrshires and the Shorthorns—animals that would appear to be not only bred, but reared, and cultivated for diametrically opposite uses. The over-feeding of the Shorthorn, so that he shall do nothing but make flesh, is an old story. Mr. Home dwelt upon it at some length:—"I am far from thinking that if you keep them according to the present English rules you will be greatly benefited by them. Some of the means at present adopted go to deprive the animal of its milking powers, and render it unnatural in its inclination to take on fat; but if they are made to keep in a good, fair, growing, breeding state—in fact, in that state of exuberant health which makes them suitable for breeding—the country would greatly benefit by their introduction. Unfortunately, the great run has been upon shape only, to the neglect of milking and breeding qualities. I may mention, in confirmation of my remarks about the fattening of the Short-horn, that I was at the Newcastle show of the English Society some years ago, and was going round the yard with Mr. Booth of Killerby. He was reckoned the first breeder of fat stock in Yorkshire, and was only equalled by Mr. Bates, whom he never liked to meet, so close was the competition. Mr. Booth's cattle were very high fed; and one cow he had at that show (Necklace, I think, was her name) was as magnificent an animal as one could wish to behold. But then she had, as it were, pillows of fat sewed on to her hind quarters and along her back. I remarked that the calves of such an animal must be very valuable. He answered, 'I am sorry to say I have been rather unfortunate in that respect—the calf died.' After expressing my regret, I said, 'Do you not think she is rather fat?' He said that perhaps she was a little."

The Ayrshires are to be condemned for the very reverse of all this. "It is a breed generally allowed to be superior to all others for quantity of milk. The

Ayrshire breeders have, for many years, been driving at that point—namely, good milking qualities, and I regret to say that I fear they have done so to the neglect of the feeding qualities. A recent writer, speaking of Ayrshires, says, that one cause of the pleuro-pneumonia is that they are bred too fine, and I am of opinion that there is some truth in this. The same writer also said, that if a breeder has a first-rate bull, he was put to his nearest relations, to his own mother, daughters, or cousins, thus breeding too much in-and-in. Whatever causes operate to produce the effect, I do not pretend to say; but it is an acknowledged fact the Ayrshire breed are deficient in beef and growing qualities. They are, generally speaking, narrow in the chest, and cannot have a large development of lungs, so that they may be predisposed to take injury or catch cold."

The difference between the two is yet further demonstrated. If the Shorthorn is fed *up* the Ayrshire is as systematically fed *down*. Mr. Gray, of Bearside, was once leaving the house of a friend where he had been to buy a bull, when he saw an Ayrshire calf which could scarcely move about. He asked what was the matter? "Nothing," said his friend, "only we must starve the calves the first year to make them fine, or they would grow up large coarse animals."

The point of the debate was, nevertheless, all in favour of the Shorthorn. As a cross for almost any kind of Scotch cattle there is clearly nothing equal to them. "Mr. Bates, of Kirklevington, once told me (Mr. Home) he had got a lot of West Highland heifers, and put Shorthorn bulls to them; thus producing the most admirable animals he ever saw—pictures of many of which he had hung on his walls." Mr. Stobie, of Ballochneck, not only confirmed this, but went on to mention that he exhibited two cross-bred heifers at the recent show of fat cattle at Glasgow—one of which gained the first prize, and was out of a small Ayrshire cow, by a pure Shorthorn bull; it was a very fine animal, and admired by every one. "He had no hesitation in saying the Shorthorns, and first crosses were the easiest fattened breed, and in times like these, when the farmer must get his goods quickly to market, they were the best." Mr. M'Nellan had found the Shorthorn the easiest fed, and a cross between the Shorthorn and Ayrshire exceedingly useful—in fact, as easily fed as the Shorthorns; and, while he had reared this class to 50 stone, he could not rear an Ayrshire to more than 35. And Mr. Chrystal was of opinion that a Shorthorn bull with Angus cows would make an excellent animal; but, if such were done, he would stick to the first cross, and never cross again.

The Chairman, in his reply, even took up the cudgels for the Shorthorns on their weak point: "The milking qualities of the Shorthorns were fully equal to the Ayrshire. All the dairies in London were filled with Shorthorns, and the Londoners were pretty well up to the way of getting most value for their money. He had known one Shorthorn cow that gave 18 Scotch pints (36 quarts imperial) of milk per day, and the amount of butter he did not recollect, but it was something immense; while at Keir he believed there was a Shorthorn cow which was a most magnificent milker. All this went to show that the Shorthorn breed contains all the good milking properties, but they had been destroyed by endeavouring too much to get a monstrous fat beast." There is a great deal of truth and sound sense in all this. Indeed, we must especially compliment Mr. Home upon the manifest justice with which all his remarks were made, as well as upon the great attention he has clearly given to his subject. Cattle are not merely fed too highly for breeding purposes, but even it is said for that of consumption. A London surgeon has recently been alarming the town by a declaration—founded upon *post mortem* examination—that there was scarcely a beast exhibited at the Smithfield Club Show but was so grossly over-fattened as to be unfit for human food! Without going quite so far, the abuse at our summer stock shows is altogether indisputable. Scotland itself affords a very recent and striking example of this. The famous "John O'Groat," the first-prize bull this year at both the English and Scotch national meetings, and one of the grandest Shorthorns ever seen, has since died. Mr. Home, "for one, however, was not altogether unprepared to hear of such an event. If an animal is fed up to a state quite unlike healthy nature, as the rage is at present, what else can be expected?" This may not be very palatable to some of our friends, but a *home truth* may do them more good than they may at first be willing to admit.

We have followed out this discussion with much interest and satisfaction, and hope ere long to have to chronicle some such similar inquiry on this side of the Border. The new number of the Royal Agricultural Society's Journal has a very able paper on the Implement Show at Salisbury, but not one word as to the live stock. And yet our "different breeds of cattle" is no so unimportant a thesis, after all.

THE CONDUCT OF THE PARIS MEAT TRADE.

We recently referred to the price of cattle in France and England, showing that the British grazier had no reason to fear a competition with our French neighbours. We now publish, on page 292, of this number, a paper on the production and consumption of meat in France, and the effect of the present law upon the price of meat, in Paris particularly, and generally throughout France. We are sure that this paper will not only be perused with interest by the English grazier, but it will excite some surprise at the clumsy apparatus set to work for the regulation of the sale of meat by the French Government, to the destruction of all competition, and the encouragement of every species of fraud and peculation on the one hand, and unmerciful exaction of dues necessary to support the system on the other. Between the public taxes and the private plunder—the latter connived at by the functionaries specially employed to protect the public interests—both the producer and the consumer are robbed right and left; whilst the only persons benefited by the system are the butchers, who make enormous profits. In the mean while, the production and grazing of cattle decrease in France, and the quality of what is produced is deteriorated by the operation of the law, and the ruinous deductions between the grazier and the consumer; and the consumption is checked by reason of the high price of meat, the consequence of the prohibitory exactions, amounting to about 3½d. per kilo. on ox and cow beef, 4½d. on veal, and 6½d. on mutton; or on an average from 1¾d. to 3¼d. per lb.

The enhancement of price, however, is not the only evil of the system. By the law, the butchers are bound to make four kinds or classes of meat, and also to sell

cow beef, *as such*, at a lower rate than ox beef. But they have found a means of evading the law in both respects so effectually, that although it is notorious that a vast proportion of cows—generally old and past working and milking—are slaughtered in Paris, *no cow beef* is ever to be seen upon the stalls; and on the other hand, no beef of the fourth or most inferior class, and very little of the third class, is exhibited for sale. The just inference therefore is, that both the cow beef and that of the inferior classes of meat are transferred and merge into the first and second classes, to the extra profit of the butcher, and injury of the public.

To these evils of the present system must be added the enormous quantity of *dead* meat (la viande à la main), generally diseased, slaughtered clandestinely beyond the barrier, and brought into Paris. This in 1846 amounted to 4,560,000 kilos.; but in 1856 it rose to 17,151,000 kilos., or nearly 50,000 head of cattle. We admit that our London market is liable to the same species of imposition, and that large quantities of diseased meat are clandestinely brought thither for sale. The supervision, however, of the officers appointed by the City, to prevent its sale, have no temptation to forego their duty, on account of the free competition which exists, and that renders it dangerous and difficult, without detection, to offer such meat for public sale. The consequence is, that we continually read, in the public journals, of butchers being fined for this offence; and the proportion, therefore, sold to the public, is small compared with the general consumption.

The first and most palpable result of this system is, that the entire consumption of beef in Paris, which is but the type of all the large cities of France, is reduced to about 87 pounds per head per annum, whilst that of London amounts to about 104 pounds; the meat of the latter being almost wholly good wholesome ox beef, whilst that of the former consists of a large proportion of diseased and cow beef and veal, the cows being usually both milked and worked until they are past use for either. In the above statement, no account is taken of the sheep and pigs slaughtered in London, which would add at least from 38 to 40 pounds per head per annum to the general consumption.

But a more serious consequence of this system of the butchery of Paris is not generally appreciated, because it lies in the back-ground of the picture. This is the effect upon the general health and longevity of the population. By a comparative view of this question, as relating to Paris and London, it appears from official documents, that whilst in the latter city the mortality is gradually decreasing, in the former it is as steadily increasing. Thus, in London, the average proportion of deaths in ten years (from 1846 to 1855) has been 25 per thousand; and in 1856 it was only 22 per thousand. But in Paris, the average from 1831 to 1840 was 26; from 1841 to 1850, 28⅓; and from 1851 to 1855, 31½ per thousand! and this decrease in the duration of life is ascribed by the writer to the diminution in the consumption of animal food, the result of the present system.

Surely, if anything will open the eyes of the present astute ruler of France to the evils of the system pursued in Paris, it is a statement like the one we have given. We believe he has the welfare of the French nation at heart, and the cities of France, especially Paris, have engaged his anxious attention. How it is that he has adopted the present fatal system we cannot tell; but with the abundant evidence before him of its disastrous working, both upon the producers and the consumers of meat, we cannot believe that he will long suffer it to continue. The evils are too palpable to be overlooked, and the proofs of them too strong to be refuted. Both demand the immediate and serious attention of the French Government. The high price of meat alone, is enough to show that a change is necessary, both on account of the prosperity and the health of the population.

We have now before us a work devoted to the subject, * which estimates the general consumption of meat for all France at 7 kilos. (or 15½ lbs) per head. In Paris the proportion of neat cattle slaughtered is stated to be 78,000 oxen, 18,000 cows, and 74,000 calves. For all France, in 1840, the estimated numbers were 492,000 oxen, 718,000 cows, and 2,478,400 calves; the latter being nearly the double in number of the two former. The reason ascribed for this destruction of animal food at the very source, is the extreme poverty of the farmers, which compels them to convert their produce into money as quickly as possible. We learn that the same system is still pursued, and the consequence is that few calves are reared, and the production of meat is continually declining, whilst the price of meat advances, and the consumption proportionally diminishes. The author also accounts for the inferior quality of the cattle sent to Paris by referring to the state of the law. "Under the system of *a tax per head* the butcher purchased by preference the finest cattle, finding it to his interest to do so in spite of their high price relatively as live meat. Now, on the contrary, his interest compels him to purchase only animals of the second or third quality. He pays the *tax on the weight*, and receives no advantage from the form or strength of the animal he purchases. On the other hand, the tax being uniform, as he finds in an ox of 500 kilos. as many pieces of each class as in an ox of 300, and as he cannot sell the meat proceeding from the first at one single centime more than that of the second, he has an evident interest in purchasing only animals of inferior quality, which cost him less alive, and afford him a better profit. He neglects, therefore, beasts of superior quality, or does not offer a price for them adequate to what they cost; which tends to discourage the breeding of finer races, and lowers the quality of the meat consumed on the great market of Paris. Under this regulation the consumption of cows continually increases, to the decline of that of oxen; and the mean weight of the latter, as well as their mean value, as continually diminishes."

Such is the state of butcher's law in Paris; and its effects upon the most important branch of good husbandry in general, and upon the health of the inhabitants of Paris in particular. Efforts are making to induce the agriculturists to adopt a better system; but until the law is altered or abolished altogether, it is impossible that any beneficial change can take place.

In the meanwhile France will become an importer instead of an exporter of cattle; for it is impossible under the present system either to improve the breeds generally, or to prevent decline in the production of cattle. All writers on the agriculture of France agree on this subject, as well as that the farmers of France are more disposed to invest their savings in fresh purchases of land, or in railway and other public stock, than in the improvement either of the soil or of the breeds of cattle. There are undoubtedly exceptions to this, but it certainly applies to the large body of farmers in that country, and is the bane of its agricultural prosperity.

* "Question des Subsistances—solution, le pain à soixante centimes les deux kilogrammes;" &c.

ON THE PRODUCTION OF ANIMAL FOOD.*

[TRANSLATED FROM THE FRENCH OF "LE JOURNAL D'AGRICULTURE PRATIQUE."]

No one disputes the importance of the bovine race of animals, in connexion with the slaughter-house; nor, on the other hand, does anybody appear to doubt that we have taken a wrong course in that great question—the production of meat.

Both the consumption increases and the price advances continually. People are uneasy at this, and inquire the reason, which is very simple: Production remains stationary, and is not in accordance with consumption; and it has remained stationary because it is not sufficiently profitable to the agriculturist.

The remedy for so serious a state of things is not easy of application; for, in some degree, it requires the co-operation of every one, and, above all, the vigorous support of authority, which should have the sole power of effecting a reaction in the tendencies of the market.

The most liberal encouragements lavished upon the breeders of cattle would not be too much, at this time; and they should, undoubtedly, bring the consumption to modify itself to something like what it is in England, which is at once more profitable to agriculture and to the public health than what is taking place in France.

In France, the number of horned cattle amounts, in round numbers, to ten millions; that of cows being four millions, and of calves three millions. Of these latter they kill two-and-a-half millions per annum, which do not yield more than 30 kilogrammes of meat (about 66½lb.) per head. We slaughter, besides, 1,500,000 head of large cattle; and this total of four million head yields four hundred million kilogrammes (886,070,000lb.) of meat.

In England, with eight million head, they slaughter only two million; and that number yields five hundred million kilogrammes (or 1,107,587,500lb.) of meat.

Yes: in France, four million head yield four hundred million kilogrammes; and in England, two million yield five hundred million kilogrammes of meat. The cause is that, in England, they kill neither so many calves nor so many old oxen; and it is this correct and skilful proportion that gives them an economic position much superior to that of France in this respect.

The first and most important of the encouragements to be given for the production of cattle is, an entire change in the present customs of the slaughter-house. "Freedom," they say, is about to succeed monopoly in the great market of Paris, and to respond to the incessant and just complaints of the consumers; which is good news. The freedom of the slaughter-house is as useful to agriculture as to the consumer; for it will suppress a part of those intermediaries who absorb too large a share of the price, and cause the consumer to pay too dear for the meat, whilst the producer sells it too cheap, and is, consequently, disgusted with the market produce.

Let us judge of this by the following statement, which is taken from official documents, and which shows that the average price of an ox weighing 350 kilogrammes (775lb.) of net meat is 314f. (£13 1s. 8d.), or per kilogramme 89c. to 90c (or about 4d. per lb.) Certainly, there is a considerable distance between this price and the selling price of meat; and if, as ought in justice to be the case, the greatest part of it accrued to the grazier, his advantage would be a powerful encouragement to production. But, besides the indispensable intermediation of the butchers, there are others of all sorts. There is the Pay Office of Poissy, which charges, besides an interest of five per cent. upon the loan granted to the butcher, a municipal right of 3c.; which led M. Chale to say, in his deposition before the Parliamentary Inquiry made in 1851: "The Pay Office of Poissy is an instrument with which the city of Paris takes 1,400,000f. from the pockets of the agriculturists, under the pretext of ensuring their payments, which they do not ensure at all." Next, there is the town due of 2c. per kilogramme, and the abattoir tax of rather more than 7c., making in all 15c. 3½ milles.

But still this is not all. There is, in consequence of the law which makes it imperative to bring all the animals to the markets of Sceaux and Poissy, intended for the supply of Paris, at least one purchaser at first hand, who forms the groups of cattle, and conducts them to the privileged market; but there are more frequently two, three, and even four intermediate dealers, whose exactions are not less than from 10c. to 15c. per kilogramme each. There are also the commissioners near the same marketa; the guides, to show the way from Sceaux to Poissy, and from Poissy to Sceaux; the hay-merchant; and the lodging-house-keeper: and all these people have their share of the benefit that the consumer ought to pay to the producer. It also raises the price of meat from 6c. to 8c. per kilogramme, on the average.

I am aware that all these middle-men cannot be suppressed, but they may be considerably reduced in number; and they ought to be placed on a well-understood footing. Nor can the production of cattle make any important advance whatever until the agriculturist shall be fully satisfied and secured in this respect.

Light breaks in on every side, and the most interesting publications are applying the torch to those questions which the interest of the Paris butchers hold in voluntary obscurity. Documents abound; and we can obtain from them a knowledge of abuses of all kinds, which ignorance alone of the facts has suffered to exist to the present time.

It is to the parliamentary inquiry commenced in 1851—which the political events of that period prevented from being completed—to which is due the merit of the deep investigation of this question. The documents collected at that period are the basis and starting-point of all the publications which have since been issued. They display such a character of honesty and truth, that we have felt secure in quoting them; and they are found continually under the pen of every writer. One of these, amongst others, M. E. Blanc, in his "Mysteries of the Butchery," supports by that authority the result of his personal works. M. Blanc does not draw conclusions in favour of freedom; he would substitute one monopoly for another. But his statements are, nevertheless, interesting and instructive; and I shall borrow from him some of great importance.

The price of beef at Paris, in 1820, was from 55 to 60 cents. per pound; in 1841, according to the report of M. Boulay de la Meurthe to the Municipal Council, 70 cents.; and it has successively risen from that time to 100 and 104 cents. (or 10d. to 10d. 1-25th per pound)—an increase of 90 per cent. in thirty-six years, and that in spite of all the efforts of the Administration to reduce the price of meat, and a multitude of opposite measures contradictory and incessantly reviving, with the view of remedying the evil. "He has been assured that the butchers of Paris could sell meat retail at 10 cents. less per kilogramme than they purchase it, on account of the skin and other proceeds."—[Parliamentary Enquiry (French) of 1851, vol. i. p. 32). Now, the mean course of the averages of the markets this year (1857) quotes meat at 1 franc 40 cents. (1s. 2d.), and this price is imaginary—"because the butchers have an interest in raising fictitiously the price of live cattle, in order to justify them in selling dearer by retail."—[Report of M. Boulay de la Meurthe, 1841.]

Let us, however, accept the quotation of 1 franc 40 cents.; the average retail selling price has been 1 franc 98 cents., or 58 cents. (5¾d.) *more* than the cost price, instead of 10 cents. less.

The following is, under another form, the butcher's amount:—

		F.	C.	F.	C.
Cost price of meat				1	40
Selling price..	Retail price....	1	98	2	32
	Skin and other proceeds....	0	34		
Profit.....				0	92 cts.

* Taken from the second edition of "The Principal Bovine Races of France, England, and Switzerland," by the Marquis of Dampierre.

But this is not all: we must now state the less palpable profits which accrue to this return of 2 francs 32 cents., namely—

1st. The coarse meat imposed upon the purchaser, *in spite of the regulations of the Prefecture of Police*, amounting to *one-fourth*, and more frequently to *one-third* of the weight; say 40 cents. per kilogramme.

2nd. The substitutions of one class for another, or the deviation of the general amount from the classes, 40 cents. per kilogramme.

3rd. The sale to the tallow-melter of the fat from the carcase (about 15 kilogrammes per beast); of the loose fat and skin, charged according to custom, at the price of the meat (1 franc 98 cents. per kilogramme), and thrown into the basket, then sold a second time (about 10 kilogrammes, at 1 franc 20 cents. per kilogramme). Total, 25 kilogrammes. Making a profit, on an average, of 49 francs 80 cents. per beast, or 1 franc 45 cents. per kilogramme.

4th. The sale of 20 kilogrammes of bone allowed to the butcher upon each bullock, and reckoned by the Prefecture of Police at 20 cents. per kilogramme, and which they sell at the price of meat (1 franc 98 cents).

5th. The kidneys and false-chines, the normal weight of which is 20 kilogrammes; to which must be added 20 other kilogrammes, taken from the first, second, and third classes.* The whole sold at 3 francs per kilogramme.

6th, and above all, we must reckon the skill with which the meat is managed, so that there never remains a morsel for the fourth class, and but little in the third; by which it is estimated that they gain 1 franc per kilogramme on the fourth class.

Now, there is still the substitution of cow beef for that of ox; the difference in the price being from 48 to 50 cents. All the butchers kill cows, of which, on an average, 25,000 per annum are killed in Paris; and they are right in doing so, for that meat, although we say it, is as good, and often as fine, as that of ox beef, depending on the quality and health of the animal. We never, however, find any cow beef amongst the butchers; they scout, as an insult, the inquiry for it. The reason is, that cow beef is transformed into ox beef as soon as it appears upon the stall, and this fraudulent substitution constitutes an average net profit of 149 francs 54 cents per cow (or £6 4s. 2d.) on all that are killed.

With all these enormous profits, what are the expenses to be deducted? They are as follows:—

	fr.	c.	m.
The cost price	1	40	0
The municipal duties	0	12	34
The expenses of the stall	0	8	50
	1	60	84

These results are so important, that the skill of the butchers has been exercised successfully to conceal them up to the present time. It is high time to give a complete statement of them; for the profits accruing from them ought to be shared by the graziers, who, up to the present time, have been simple enough not to lay any claim to this fifth quarter (*cinquieme quartier*), which nevertheless amounts to 126 fr. 90 c. per head, or 36 c. 78 m. per kilo., upon 345 kilos. of ox beef; 75 fr. 90 c. per cow, or 3 c. 45 m. per kilo., on 220 kilos. of net meat; 29 fr. 30 c. per calf, or 45 c. per kilo., on 68 kilos. net meat; and 11 fr. 60 c. per sheep, or 64 c. per kilo., on 18 kilos. of net meat.

This mysterious fifth quarter does not amount to less than from 18 to 20 millions of francs profit per annum to the Parisian butchers alone. Judge then of its importance to the grazier!

The calculations which attribute an average profit of 34 cents. per kilo. (3¼d. nearly) as the result of this fifth quarter, are based upon the average of 1856. Those of 1857 are higher, and exhibit an increase of 22 fr. 10 c. per ox, 14 fr. 95 c. per cow, 6 fr. 33 c. per calf, and 2 fr. 22 c. per sheep. They consequently increase proportionally the profit, estimated too low at 34 c. per kilo, raising it 36 c. 78 m. for ox beef, 34 c. 5 m. for cow beef, 45 c. for veal, and 64 c. for mutton.

In order to complete this useful information for the graziers, we give the prices in the actual returns of the several parts of this calculation.

	fr.	c.
Ox Beef—The skin, average weight 47½ kilos.	53	90
Tallow and fat „ „ 50 kilos.	56	0
Offal (lights, liver, spleen, brain, tongue, gall, and paunch)	12	0
Total	126	90
Cow Beef.—Skin, average weight 35 kilos.	45	50
Tallow „ „ 20 kilos.	22	40
Offal (as before)	8	0
Total	75	90
Calf.—Skin, average weight 7½ kilos.	16	50
Tallow „ „ 4 kilos.	4	80
Offal (head, tongue, brain, sweetbread, pluck, and stomach)	8	0
Total	29	30
Sheep.—Skin in the wool, mean value	6	0
Tallow, average weight 3 kilos.	3	60
Offal (head, tongue, brains, feet, kidneys, and stomach)	2	0
Total	11	60

All these figures are taken from authentic sources. Let us consider what an enormous bearing they have upon production. We would wish that in this point of view it may attract serious attention; and that, when once delivered from the monopoly, means may be found to make the butchers pay for all those parts which have a value as high and real as the meat sold to them.

Let us now see what influence the price of meat has upon consumption, and especially on the qualities consumed. An English work, "*The Night Side of London*," has published some very interesting statistical documents on the consumption of London. There are eaten in that city annually 277,000 oxen, 30,000 calves, 1,800,000 sheep, 35,000 pigs, &c. On this statement M. E. Blanc makes the following reflections:—

"If we refer to the consumption of Paris, we find that that annual average consumption, for a population which amounts to only half that of London, is 88,000 oxen (only one-third of the consumption of London), 77,000 to 80,000 calves (nearly two-thirds more than are consumed in London), and from 20,000 to 25,000 cows, &c.

"Now, reducing these classes to kilogrammes, we find the following differences between the alimentary conditions of the two capitals:—

"The 277,000 oxen of London, superior in weight to those of the French oxen, and weighing in net meat a minimum of 400 kilos., allow for the 2,360,000 inhabitants of that city 47 kilos. per head; and the 30,000 calves, a food destitute of all nutritive qualities, 86 grammes only.

"The 88,000 oxen of Paris, on the contrary, weighing on an average 345 kilos., allow to the 1,200,000 inhabitants of that city only 25 kilos. 300 gr. per head; and the 77,000 calves 5 kilos.; which makes a difference in favour of the population of London of 24 kilos. 70 gr. of beef per head, and a difference in favour of the population of Paris of 4 kilos. 14 gr. of veal—the former being *substantial*, and the latter *unsubstantial* food.

"These statements explain why the work of which we speak thinks itself authorized to say, that '*London is the city in the world where they live the longest. In ten years the average of deaths has been 25 per thousand; and in 1856 that proportion was reduced to 22 per thousand.*'

"If, in order to complete the comparison, we consult the mortuary statistics of Paris, we find in them, by the statements of the English work, a sad contrast in the constant progression in the deaths, the average of which was, in 1831 to 1840, 26 per thousand; in 1841 to 1850, 28½ per thousand; and in 1851 to 1855, 31½ per thousand.

"Perhaps the price of meat at these different periods will explain to us the cause of this deplorable mortuary progression."

"From 1831 to 1840 meat sold at the stall from 60 to 65

* By the law in France, the butchers are bound to divide their meat into four classes, and sell it, according to the quality, at a certain price, fixed by the Prefecture of Police.—[Translator.]

cents. (6d. to 6½d.) per lb. It rose from 1841 to 1850, to from 70 to 75 cents.; and we have seen, from 1851 to 1855, and afterwards, it has attained a rate assuming from day to day more of a prohibitory character.

"Is it not expedient here to recall that fearful declaration made before the Commission of Inquiry of 1851, and quoted in page 101 of this work, that *when the consumption of meat decreases*, THE MORTALITY INCREASES IN AN ANALOGOUS PROPORTION?"

We have here certainly matter for serious reflection, and motives for endeavouring to bring back the production and consumption of cattle, that source of public health, to conditions equitable for all.

Could agriculture produce meat in a profitable manner, by producing more, and at the same time considerably diminishing the price to the consumer? Certainly yes; but, in my opinion, three conditions are necessary, in what relates to the butchery of Paris, and these measures would have an immediate and decided influence upon the butchery of the rest of France, which, without reaching the impositions of the Paris butchery, tends to copy its proceedings in its own. These three conditions are as follow:

1st. Free-trade for the butchery—that is, competition. A vigilant authority may, by measures more efficacious than those which now exist, survey more closely the quality of the meat. It could not make the matter worse, in any case, however evidently disposed to do so; for fraud has been introduced everywhere, and the existing monopoly lives only by the violation of the laws and regulations which govern the matter.

2ndly. The suppression of all the middle-men and all the duties which are placed between the producer and the consumer. Let there be only the butcher, and the municipal and abattoir charges, reduced to 5 or 6 centimes.

3rdly. The creation of one market only, within reach of Paris, and thereby the suppression of the 8 or 10 centimes which tax the meat of animals usually driven from Sceaux to Poissy, from Poissy to Sceaux, or from Sceaux or Poissy to Paris, to the great injury of their health, their weight, and the quality of their meat. By this arrangement, again, we might look for a more strict and real attention than that which a director of Abattoir intimated in the following terms in the Legislative inquiry of 1851:—"It is certain that the inspection of the markets is completely illusory; for the inspectors inspect nothing at all. They do on the market just as they please, and the public find in it no guarantee. There come animals in the most deplorable condition; the inspectors never see them; and then even if they did see them, it is a question whether they would prevent the sale of them."

The establishment of a single market, and within reach of Paris, might involve other desirable measures; for instance, the verification of meat, which every one declares to be of a quality frequently wretched; and by this means the prevention of the entry into Paris of *dead meat*, or that of animals killed beyond the Barriers, most frequently diseased, and killed clandestinely. The consumption of meat under such circumstances assumes a frightful proportion; for in 1856 it reached the amount of 17,150,000 kilos., being a third of the consumption of meat proceeding from the Abattoirs; whereas in 1818 it was only 366,000 and in 1846 4,653,000 kilos.

All meat which has not passed under inspection alive ought to be proscribed: it is the only means of insuring a healthful alimentation.

Such is the state of this great question of the butchery, so important in all points of view for agriculture, and so worthy of engaging the attention of all reflecting men.

E. DE DAMPIERRE.

PRESENTATION OF PLATE.

TESTIMONIAL TO MR. R. T. BECKETT, OF TARPORLEY.

On the occasion of the rent-day in December last, in connection with the estates of Sir Philip de Malpas Grey Egerton, Bart., M.P., a general feeling was expressed by the tenantry that some mark of their appreciation of the honest, courteous, and exemplary conduct of Mr. R. T. Beckett, the agent, was called for; and no sooner was the sentiment expressed, than arrangements were made for bringing such good wishes into a tangible shape. A committee to obtain subscriptions and arrange details was formed, consisting of Mr. J. Vernon, of Willington (chairman), and Messrs. Warburton and Barnes, of Eaton; Messrs. J. Barker, Finchett, and H. Siddon, of Rushton; and Mr. Rigby, of Fenna Wood. Mr. William Vernon was appointed secretary. The intentions of the committee were at once announced, and tenants on the Oulton, Broxton, Astbury, and Upton and Chester estates, all came forward with their contributions from £2 to 1s., to pay a tribute of respect to the man who for 23 years had discharged the onerous duties of land-agent with fidelity to his employer, and at the same time with benefit to the tenantry. So unanimous was the feeling, that in a week or two £140 was subscribed; and to add to the general gratification, Sir P. Egerton expressed his hearty approval of the whole proceedings. After some little consideration, the committee determined that the testimonial should consist of a handsome, but useful collection of silver-plate. The articles comprised a dozen silver table forks, a dozen dessert ditto, a case containing a dozen dessert knives and forks, four silver tablespoons, two gravy ditto, massive soup ladle, salt cellars, knife rests, cruet stand, liqueur frame, bread basket, cake basket, a richly chased flower-bordered salver, an elegantly embossed kettle and stand, a dozen Queen's pattern teaspoons, and a splendid gold watch and chain. A purse containing 30 guineas was also added to the above-mentioned articles. Accompanying the present was a beautifully emblazoned and engrossed list of the articles, and also the names of the various subscribers to the testimonial. On the kettle, salver, and watch, the following inscription was engraved—"Presented, with other pieces of plate, by the tenantry of Sir Philip De Malpas Grey Egerton, Bart, M.P., to Mr. Richard Trim Beckett, as a token of their admiration of his courteous conduct, and of their high regard as an honest and efficient agent for the last twenty-three years. 10th February, 1858." The ladle, spoons, &c., each bore some part of the inscription, denoting that they formed portions of the testimonial.

In order that the tenantry generally and the friends of Mr. Beckett might have an opportunity of paying their personal respects on the occasion of presenting the plate, it was decided that a dinner should be held at the Red Lion Inn, Eaton, near Tarporley, on Wednesday last. Early in the day, the indefatigable secretary, Mr. Wm. Vernon, had tastefully set out the articles of plate in a small room at the Red Lion, where they were inspected by nearly 300 of the ladies, gentlemen, and labourers living in the neighbourhood. At two o'clock

THE DINNER

took place in the large room of the inn, when about 90 of the tenantry sat down. Amongst the company present we noticed Mr. John Vernon (chairman), Mr. R. T. Beckett, Mr. Beckett, and Mr. W. Beckett, Northwich; Mr. Moss, Shaw Farm; Mr. Hicklin, Chester; Mr. Brown, Broxton; Messrs. Baddeley, Leadbeater, Robinson, and Bivy, Astbury; Messrs. Bithell and Beecroft, Upton; Messrs. R. Taylor, Rigby, and Hyne, Little Budworth; Messrs. W. C. Warburton, Barnes, Law, Ruscoe, Finchett, and Barker, Eaton; Messrs. Bebbington and Siddon, Broxton; Mr. Shrigley; Mr. Johnson, Egerton Hall; Messrs. Hitchens and Bretley, Rushton; Messrs. Ellwood and Rowe, Kelsall; Mr. Davies, Egerton; &c., &c.

After the dinner had been disposed of, the Chairman proposed the usual loyal and complimentary toasts; after which the health of Sir P. Egerton (the landlord) was drunk with three times three.

The testimonial was then placed by Mr. Butt in front of

The CHAIRMAN, who rose and said—Mr. Beckett, the committee formed for the purpose of providing some substan-

tial memorial to mark the high estimation in which you are held by the tenantry of Sir Philip Egerton, have done me the honour to appoint me their chairman, in which capacity I now stand. Proud I am of the duties entrusted to me, though very far from being able to discharge them in a manner that I would wish; but I am quite sure you will excuse me when I say you must take the feeling of the heart for the will of the mind. During the time you have been amongst us, which now extends over the long period of twenty-three years, we have had very many opportunities of witnessing the unremitting care and attention with which you have discharged your important duties as agent to our worthy landlord. I can say from experience, when you have seen it needful you have not been backward, with the kind consent of your benevolent master, to render us every assistance in your power; and now, sir, on behalf of my brother-tenants, whose names are herein written, I beg your acceptance of the accompanying testimonial as a mark of the esteem we bear towards you, and also as a small return for the many acts of kindness you have done us, and for the uniform good feeling and gentlemanly manner with which you have treated us; and we hope and trust that your valuable life may yet be spared many years to us and to your esteemed wife and family, and that you may be permitted by a gracious Providence to pursue your career of usefulness in the enjoyment of every blessing this world can bestow. And when declining years come on, may you view that tribute of respect with delight, and say "I have won those for an example to a rising progeny and ages yet unborn;" and when it pleases God in his infinite mercy to call you hence, "may you die the death of the righteous, and may your last end be like his." And now, gentlemen, I call upon you to show your further wishes to our worthy guest by filling a bumper to his good health, with the honours due to a hearty good fellow.

The toast having been drunk amid enthusiastic cheering and musical honours,

Mr. BECKETT rose and said: Mr. Chairman and Gentlemen, I rise with no ordinary feelings of gratitude and pleasure to receive from your hands this valuable testimonial, as a mark of the estimation in which you hold my conduct and services as land-agent to Sir Philip Grey Egerton. More than 23 years ago I entered upon that appointment with the highest gratification, and I soon found that I had to work with an intelligent and improving class of farmers, who only required confidence and encouragement, not dictation. I also found, as I expected, the nobleman whom it was my duty to serve and represent, to be a most liberal-minded landlord, whose greatest desire and happiness was to improve the condition of his tenantry, to make their homes comfortable and condition prosperous. I further found in Sir Philip Egerton's professional agent, Mr. Humberston, the present Mayor of Chester, a most gentlemanly and agreeable adviser, easy of access, and always at my right hand whenever I required advice. Under such circumstances, and with such advantages, it was no difficult duty for me to sail smoothly with you in all matters connected with a land-agency. My course has been as smooth as an unruffled sea. I am proud to say that I have never had to encounter a head-wind or a stiff gale; nor do I yet see any breakers ahead, except the chance of a break-down in my attempt to acknowledge your great kindness on this occasion. While the brilliancy of your magnificent testimonial dazzles my eyes, my heart throbs with gratitude which I cannot fully express. I value it for its intrinsic worth, but still more because it comes from a respectable disinterested tenantry, with whom I have had the honour to act for so many years. I little thought when I entered upon my stewardship, that the 1st October, 1834, would be the harbinger of such a day as this. I thank you all most sincerely. I thank also my absent friends, the tenantry, who have contributed to this testimonial, which I shall endeavour to hand down to my children as unsullied as I receive it at your hands. May health and happiness attend you and your families, and may the tenantry of the House of Oulton always be as united and prosperous as their warmest friends can desire; and believe me that amongst those friends you have none more sincere than Sir Philip Egerton your landlord, and your humble servant his land-agent. Mr. Chairman, I beg leave to thank you individually for the kind and flattering manner in which you have been pleased to present this testimonial; also to you, gentlemen, for the patient hearing you have given me, to enable me most inefficiently but most sincerely to acknowledge the high compliment which you have paid me.

The health of Captain Egerton was next drunk.

Mr. HICKLIN, in a speech expressive of the pleasure he experienced in seeing so good a feeling existing between landlord, agent, and tenantry, proposed "Success to the Flail and the Plough."

The healths of Mrs. Beckett, the Vice-Presidents, the Committee, the Secretary, the Press, of Mr. Butt, and thanks to him for his exertions to obtain so handsome a testimonial, with other toasts, were proposed and duly responded to, the entire company enjoying the occasion in a happy, convivial manner.

THE GUANO TRADE A MONOPOLY.

As a convention of the Peruvian Legislature is now sitting at Lima, as to the future disposal of guano, whether it is to be continued as a monopoly in the hands of the present consignees, Messrs. Baneda Brothers for the United States, Anthony Gibbs and Son for Great Britain, and the agent for France and the continent, or opened for free sale at the islands, it may be interesting to know a little of the trade and of the immense profits made by the consignees. The shipments to this country and England for 1854, being in round numbers 163,000 and 200,000 tons (those to the continent not included), will show the great interest the consignees have in continuing things as they are, and the necessity of our citizens and the English exerting themselves to open the trade to the public:—

SOLD IN THE STATES IN 1854.

	dolls.
163,000 tons at 55 d., 8,965,000 d.; com. 5 per cent.	448,250
„ freight 20 d., 3,260,000 d.; com. 2½ „	81,500
The consignees get this on all charters, no matter how many ship-brokers are interested in the other half.	
Estimating 163 vessels as loaded, and that 3,000 ds. were drawn for disbursement, the profits on advances of Peruvian dollars, worth about 75 c.	125,000
	654,750
Messrs. A. Gibbs and Son, in proportion, would amount to.....	813,000
There are other commissions on advances, storage, &c.	

Memorials had been presented by the British landowners, farmers, shipowners, and merchants to the government, to use their influence to have the monopoly so injurious to the public good done away with; but hitherto their exertions with the Peruvian government have been unsuccessful. However, there is now a hope, as the Peruvians think a change ought to be made. The ministers of both countries should render their assistance for so desirable an object.

Though freights have fallen considerably since 1854, the price of guano has been raised from 55 dols. to 62 dols.

When at the Chincha Islands a few years ago, Mr. Elias had the contract for shipping, at nearly a dollar over the tender of Mr. Lloyd, though backed with good security. This would be a charge extra of 400,000 dols. a-year to the farmers, estimating the annual shipments at that amount. The vessels were then delayed a month, by having to enter and clear at Callao.

In 1851 the price of guano, with higher freights than at present, was 45 dols. This year the English agents attempted to raise the price to 70 dols., being 8 dols. over the rates here, though the charges were the same; but it failed, owing to the *Mark Lane Express* calling the attention of the farmers and the trade to its injustice. 500,000 tons could be annually shipped from the islands, which at 20 dols. would give a revenue to Peru of 10,000 000 dols. (less the shipping charges), and with 20 dols. freight would make guano stand 40 dols. afloat, instead of 60 dols., as under present management.

This is a question of importance to the farmers of the world. —Hunt's (American) Merchants' Magazine.

THE CULTURE OF SHEEP.

A LECTURE BY MR. ROBT. SMITH, OF EMMETT'S GRANGE, SOUTH MOLTON, DEVON.

On Monday evening, Feb. 22, a lecture was delivered by Mr. Robert Smith, of Emmett's Grange, South Molton, Devon, in the new lecture-theatre of the South Kensington Museum, on "The Culture of Sheep," being the last of a series of six addresses to working-men, and intended to explain the collections of the animal kingdom in the museum. The attendance was very large, there being at least 500 persons present. The lecturer produced a great number of pictorial sketches of the various breeds of sheep, English and foreign, which added materially to the interest of the lecture; they being frequently referred to in elucidation of the subject.

After some introductory observations—in which Mr. Smith spoke of the advantages offered to working men in that institution, and observed incidentally that in going over the museum he had found that the collection of specimens relative to the culture of sheep was incomplete, and that he would do what he could to supply the deficiencies—the lecturer proceeded to bring before the audience the subject of his lecture. The culture of sheep was, he said, a branch of their rural and national economy which had not as yet received that degree of public attention which was due to it. As a rural occupation it was the foundation of all good husbandry, and in a national point of view they looked to it as a means of employment for thousands of their artisans, and as an important source of food and raiment for an increasing population. They found from history that sheep had existed at the earliest periods in every quarter of the globe, from Iceland to the regions of the torrid zone; but they had been most cultivated in Europe—especially in Germany, Spain, and Great Britain; and not only had the cultivation of sheep in this country recently outstripped that of every other country, but they were daily witnessing a new and important auxiliary in the culture of sheep in the British colonies. As he had already intimated, sheep were found in every quarter of the globe. Thus they were to be met with in every variety of climate, adapting themselves to the vicissitudes of heat and cold. In each country they were cultivated according to the wants and tastes of the people, whether for food, clothing, or the uses of commerce; but when left to themselves, under the operation of Nature's laws, they represented every form of carcase and clothing which corresponded to or fitted them for the particular climate and country in which they existed. Sheep when in a wild state preferred to range at large on open plains, and displayed considerable sagacity in the selection of their food. They herded together in small flocks, and were in general active, swift of foot, and easily frightened by dogs or men. When completely domesticated, the sheep appeared as stupid as it was harmless; but when left to depend upon itself for food and protection, it exhibited a more decided character. Under such circumstances a ram had been seen to attack and beat-off a formidable dog. On the approach of storms they retired for shelter to the spot which they knew from experience to be most adapted to afford it. Of all the domesticated animals of Great Britain, the sheep was of the greatest consequence both to the farmer and to the nation—to the farmer, because it was raised with ease and in situations where other animals could not exist, and generally made a better return for the quantity and quality of the food consumed than any other animal; to the nation, because it supplied a staple article of food and raiment, and at the same time afforded employment to an immense number of artisans. The culture of first-rate sheep was a "science blended with practice;" and consequently a proper knowledge of Nature's laws, more especially as regarded the effect of climate and situation on their character, had led to important improvements in their form, quality of flesh, and general management. It must not be forgotten that the sheep of the present day were, in fact, the production of man's skill and enterprise in their propagation from their original wild state. From this it might be inferred that were the breeders to relax their exertions, leaving the animal again to Nature's course, the various flocks would soon degenerate. Let them fancy for a moment such a state of things. Where then would be the advance of commerce or the increasing production of meat for an increasing population? Happily for the English nation, however, there was no cause to fear that this picture would ever become a reality. In every point of view "the culture of sheep" deserved to be esteemed one of the principal branches of rural economy, and claimed the attention of the artisan, the manufacturer, and the State. Now he must confess at the outset that he was not so familiar with foreign breeds of sheep as he was with English breeds; and therefore on that part of the subject he must call in the assistance of a very able work by Mr. Youatt. He should afterwards speak of what he himself was familiar with. The sheep which was handed down to us from time immemorial was a horned sheep. [The lecturer here referred to a picture of the original breed.] As he had before intimated, sheep were transformed in the process of propagation, by means of certain rules which were known to the breeders, and that the original breed should have been transformed into the sheep of the present day [pointing to specimens of the latter], showed how great an art was the culture of sheep. He was indebted to Mr. Davis, the Queen's artist, of Church-street, Chelsea, for the paintings and pictorial specimens before them; and when he told them that gentleman had executed the whole of the sketches since 11 o'clock that morning, they must feel he had lost no time. After referring to a representation of the Russian sheep, the Wallachian sheep, and the fat-rumped sheep, as affording illustrations of the original breed, and also to a picture of a black-faced Scotch sheep for the same purpose, he alluded to the fat-tailed sheep of the Cape, and remarked, in passing, that the tail of this sheep was esteemed so great a luxury in its native country, that it often sold for more than all the rest of the carcass. He then mentioned the Cyprus sheep, known by its spiral horns, and the Moufflon sheep, which inhabited Iceland, and resembled our deer. There were also the Asiatic argalia, the American argali, and more particularly the Merino sheep, of which he would speak at a future period of the lecture. Before he proceeded any further, he said, he ought to remark that the fine-woolled sheep were produced in dry warm countries, while strong-coated sheep were produced in wet cold countries; the coat being, in fact, adapted to the climate. From this it followed, that if the finest-woolled animals were introduced into this country, they would die away; while sheep of the opposite description might be expected to thrive. After illustrating and explaining the foreign

breeds, their localities and habits (which was an interesting part of the lecture), he would not trouble the audience with any further remarks on foreign sheep, but would proceed to speak of their own sheep. Of course England in the earliest periods of her history resembled all other countries under similar circumstances. There was nothing but bleak hills undrained plains, and wild commons; and over these uncultivated lands were found no animals but such as were in a corresponding condition. But in the course of time desolation gave way to improvement; the hills and plains were cultivated, drainage was to a certain extent effected, and with the improvement of agriculture there was a corresponding improvement in the breeds of sheep. He would first speak of the native horned sheep as originally known in this country. That picture [pointing to one] represented the old black-faced mountain sheep of Yorkshire. That animal had disappeared before the plough, and the farmers of that part of England had placed on their lands a much better kind of animals. There, again [pointing to another specimen], was the Dorset long-woolled horned sheep. Generally speaking, all the inferior breeds had given way to the better breeds; but here was an exception—the Dorset sheep remained, and the reason of this was that the lambs were produced two or three months earlier by that breed of sheep than by any other. The inferior Dorset sheep were preserved in order that the luxurious might have lamb out of season (laughter). They had no doubt all heard a great deal about the Welsh sheep [pointing to a sketch of this breed]; those sheep were fed on the waste hills of the Principality. If the hills could be cultivated, there would be a proportionate improvement in the breed of sheep; but as there appeared little prospect of that, the animal would no doubt continue in its present condition, and he need scarcely say that the Welsh sheep were altogether a naked lot (laughter). He now came to the Old Norfolks, the sheep improved by the late Lord Leicester, better known in those days as Mr. Coke. When Lord Leicester first began his career as an agriculturist, in Norfolk, he found nothing but sandy downs and a race of hardy and inferior sheep; but now the sandy downs had become fertile fields, and there was no part of the country which exhibited greater improvement, whether as regarded the cultivation of the land or the breeding of sheep. The sheep of which he had spoken had now disappeared, having been supplanted by the improved South Down of Sussex. Then as to the horned sheep. These were peculiar to the dry lands of England, it being on the moist pasture of the country that that description of animal did best. If the cultivator could get enough within five or six years from the wool and the price which he ultimately obtained for the carcase of his "old mountain wether," he was generally satisfied. He had now to refer to what were once the marshy districts of England, but which were now reckoned among the most fertile agricultural and grazing districts of the country: he referred especially to the Lincolnshire marshes. That county might be regarded as one of the best pasture districts in the kingdom. The sheep there were exposed to the eastern winds, as they fed on the low grass lands; and consequently the animals which were most adapted for that district were robust animals—animals which had a large amount of bone and fleece. He was able to speak on this subject with the greater confidence, because Lincolnshire happened to be his native county, and he resided there for a considerable portion of his life. The old Tees-Water sheep was almost a fac-simile of the Lincolnshire sheep. [The pictures of both were referred to in support of this statement.] There [pointing to a picture of a group of sheep] was a representation of the Merino. It was a sketch made by Mr. Davis, of some Merino sheep which were introduced into England by George the Third, with a view to their propagation. Notwithstanding the king's patronage, the farmers of the day would not have these foreign sheep thrust upon them; the carcase not being one that would pay, and almost the sole use of the animal being the production of fine wool, to be mixed with the coarser wools. There was a fac-simile of this breed of sheep on Exmoor Forest; and this suggested to him that though the Spaniard had propagated this animal chiefly for his wool, it might have come originally from the mountain. The Merino was a very hardy animal, its wool was remarkably thick and fine, and it was altogether a very respectable sheep (laughter). It had occurred to him that the Exmoor sheep might be mixed with the Merino to advantage; not that English farmers would consent to admit the Merino in order to improve their own sheep; but he thought their sheep would improve the Merino, by giving them more lean meat and length of wool. There [pointing to a picture] was a brown animal called "the Syrian sheep," which was a sort of Cape sheep with a long tail. This reminded him of a very interesting fact, namely, that the sheep of the earliest ages, besides being horned, were in many cases coloured. In tracing the records of history, relating to this subject, he found mention made of black sheep, brown sheep, speckled sheep, mottled sheep, and so on. So also in the present day, agriculturists sometimes saw among their flocks black sheep, grey-faced sheep, grey-legged sheep; while there was also an occasional appearance of horns. Now he felt that he had not said enough about the Merino sheep. The Spaniards and the Germans had propagated the Merino on account of the fineness of its wool. It is this kind of sheep that has been found to be most suitable for our Australian colonies. The Southdown sheep had been tried there, but had not been found to answer so well, because it was, in fact, a wild mountain sheep. In Australia, land being for the most part of little value, and rents merely nominal, an immense quantity of sheep were kept ranging over vast tracts of country; and up to a recent period, if the shearing from time to time fulfilled the expectations of the grower, he was amply repaid. Since the discovery of the gold diggings, however, and the vast increase of population, there had, of course, been people to feed as well as fine wools to be produced. In fact the people of Australia had already found themselves rather in a dilemma for want of mutton; and it might be worthy of consideration whether it would not pay some Australian agriculturists to come over here, and pay him (the lecturer) a good price for specimens of his mountain Exmoor sheep (laughter.) Now among the old English breeds that remain, there was the Dorset sheep, which was preserved, as he had stated, on account of the early lamb; the Welsh sheep, which did not appear at all likely to be improved; and the Scotch black-faced Sheep. This last sheep resembled the Russian sheep, and belonged, no doubt, to the same family. It was a very useful animal, chiefly for this reason that it lived and throve where no other breed of sheep could do so. Then there was the Exmoor sheep, which he begged to say had not disappeared (laughter), but, on the contrary, was as thriving as ever. Next there was the old Scotch white-faced horn, which, in consequence of the improvement of the black-faced sheep, and the very rapid march of the Cheviot sheep, was altogether out of date. Then there were the old Ryelands, natives of Worcestershire, Herefordshire, &c. On this subject he remarked, that it was not unlikely that the late Mr. Bakewell received considerable aid from the Ryeland sheep. Mr. Bakewell never explained to Eng-

lish breeders the course which he pursued, as they could have wished him to do, by leaving as a legacy to future generations the descriptive art of producing such a newly established breed as *his* Leicesters. He thought he obtained them originally from the Ryelands sheep. In fact [pointing to pictorial sketches of Ryeland and Leicester sheep] there we have the portrait of a Ryeland ewe, and another of a Leicester, as first improved by Mr. Bakewell. I must say, I think them so alike, that I was about to say I see no difference. A representation of one of Mr. Bakewell's sort of sheep was given in the *Farmers' Magazine*, published by Messrs. Rogerson and Tuxford, of the Strand. Many breeders thought that animal—a ram bred by Mr. Inskip—an exceedingly good one, and many ventured to assert that there never was so good an animal before, and never would be so good a one again. Mr. Bakewell produced a particular kind of animal—an animal suited to his own particular taste. At the outset he bred his sheep for form and symmetry, quality of flesh, fineness of wool, but regardless of weight. After a few years, when he had arrived at a certain state of cultivation, however much he might be admired by his friends the Leicester breeders, there were others who did not view the matter in the same light. These persons did not feel that the head required to be made smart, or the wool fine, or the bone less; they therefore resisted the new theories, and, as is stated by Mr. Youatt in his book, Mr. Bakewell was at first unsuccessful in the letting his sheep; but in after years it happened that men's minds began to change: lest the whole cultivation should be monopolised by that gentleman, a society consisting of eight breeders was formed to obtain the first pick of his flock. In the fall of the year each of these gentlemen selected a male animal, so that Mr. Bakewell's sheep were distributed as it were over the country. There was another breed of sheep which he had not mentioned, namely, the Romney Marsh sheep. This was a wild, bony, coarse animal, and he believed it had disappeared. There was another sheep, of an intermediate character, called the Devonshire Nots, a variety between the Exmoor horned sheep and the Leicester, and a very hardy animal. This was found among the high hills of North Devon and West Somerset: it was an animal which was about half way between the highly-cultivated sheep and the mountain races, and, occupying an intermediate position, was exceedingly useful in certain districts of the country. He now came to the short-woolled sheep. A black-faced short-woolled sheep was found scattered over a great many of the southern counties. Here, for example [pointing to a specimen], was a black Norfolk sheep. This afforded an illustration of what he had said before with regard to the influence of climate. Here they had changed the Old Norfolk for the Southdown sheep in the dry eastern counties of England. Then they had the Southdown on the dry southern soils, and distributed over many intermediate spaces of dry and healthy sheep-lands—which the lecturer explained, grounding every argument upon climate and improved cultivation. The Leicesters inhabit the midland counties and intermediate lands between the extreme dry and extreme moist climates of our island, the long-woolled sheep being exposed to the colder aspects, where the short-wool or pure Leicester could not exist. The localities and habits of the several breeds were then enumerated by reference to a map of England and Wales, which had been prepared by the authorities of the Institution for the purpose of illustrating the lecture. In turning to Scotland, he would remark that such was the effect of altitude that he would illustrate it in this way, by reference to a hilly district: for instance, at the foot of the hill was to be found the cultivated Leicesters, then the mixed Leicester and Cheviot, a stage further up they found the Cheviot sheep, then the mixed black-faced and Cheviot cross, and next we find the black-faced ewe, and lastly the black-faced wethers, which it was said no weather could destroy, unless blown over by a tempestuous gale (laughter). Tracing the course of the different breeds on the map, he observed that they had here long-wools, middle-wools, and short-wools. The long-wools were to be found in Lincolnshire, Yorkshire, Kent, the Cotswold-hills, and some parts of the midland counties; the middle-wools were to be found in Dorsetshire, Devonshire, Leicester, Rutland, Nottingham, &c.; while among the short-wools were the very popular Southdowns, West Country-downs, Norfolk-downs, Hampshire-downs, and Shropshires. The latter breed, he might observe, had come very rapidly into public favour, and he must confess that as an old breeder he was astonished to find them cultivated to so high a pitch, and carrying off, as they had done, prizes at our national shows. In like manner (and this is extremely interesting) there was now a new breed of sheep, called the Oxford Downs. Thus, it would be observed, were agriculturists in various districts endeavouring to propagate sheep which were peculiarly adapted to the climate and situations of their several districts. This was very important as bearing on the state of the sheep culture at the present day. The truth was that there had been eminent breeders of sheep as well as eminent men in other departments of industry; we have had our Ellman, Grantham, Bakewell, Collings, Culley, the late Duke of Bedford, Lord Spencer, Lord Leicester, &c., of the past age, who did their duty in thus handing down to us our present established breeds—breeds that have been cultivated from these indigenuous and mountain races here [pointing to the pictorial sketches]. This stage of improvement was received by men of the present generation, who have succeeded to admiration in carrying on this great work of art by propagation. Our country stands indebted to such men as Jonas Webb, the Duke of Richmond, Overman, Sainsbury, Rigden, Grantham, &c., for cultivating the South Down; to Sandy, Pawlett, Creswell, Turner, Spencer, and others for the Leicesters; while the long-wools have been remodelled by the Clarkes, Kirkhams, Casswells, Richardsons, Brices, &c., in Lincolnshire; and by Large, Hewer, Garne, Wells, Handy, Brown, and Ruck, on the Cotswold and neighbouring hills. There are many other breeders who had long directed special attention to the improvement of their breeds of sheep; and, looking at the transformations which had been effected, [here the lecturer pointed to the original and the improved breeds represented in the pictures], he must say, that if credit was due to improvers in other departments of art and of industry, equal credit was due to the breeders of sheep for the ingenuity and talent which they had displayed in their vocation (cheers). Much of the improvement was due to the Royal Agricultural Society, which had offered prizes for the best specimens of sheep. But let it be remembered, that Mr. Ellman took in hand the improvement of the South Downs about a hundred years ago; and Lord Leicester, Mr. Bakewell, and some few others, achieved immense success before numbers were at all aware what they were doing. This, of course, had a close bearing on the production of the established breeds of the present day, early corrections being thus early stamped by their males. It must not be supposed that the race of attempted improvement was all sunshine. He could give the names of a dozen or perhaps twenty breeders who had not succeeded, especially in the breeding of rams. It was no easy matter to blend science with practice. He had already mentioned the failure of the attempt made by George the Third to introduce merino sheep into this country; and he had recently learned, from the published report of an

Australian agricultural body, that its sheep-breeding operations had proved by no means satisfactory. He then proceeded to speak more particularly of the *breeding* of sheep. Adverting to what he had said about the early lambing of the Dorset sheep, he remarked that lambs were dropped according to the uses and requirements of the several counties, as regards climate, food, and after-management to be pursued for realizing in the markets, and at what age they were to be sold. The mountain races, of course, did not drop their lambs until the cold season was gone by, so that the lambs could eat the early grasses as they first sprang up. He had not yet referred to the Cotswold sheep, which was a magnificent animal [Pointing to a portrait, he said, That is a draught of a Cotswold ram, belonging to Mr. Lane, which took the first prize at the Lewes Meeting]. After giving some local details of this breed, he stated that the lambing of this sheep occurred about March; so also did that of the Leicester sheep; but he might say again that the period generally depends on situation, climate, and the supply of food. One important fact was, that at the present time sheep were, in some of the best districts, sen to market at the early age of twelve, fifteen, or eighteen months. Formerly, scarcely any sheep were sent under three or four years of age; and therefore the public had to wait for their mutton (laughter). The truth was that in many grazing counties it was formerly, and even now, difficult to provide food for fattening them in the winter season: hence, the farmer fed his sheep on the richest pastures he could give them during the summer months, in order that he might be able to send them early to market in the autumn. Another very important matter in relation to the culture of sheep was warmth. He had before referred to this, in effect, in speaking of climate; but the subject of warmth was so important as to require special mention. On this point, he would read an extract from a lecture which was delivered by Dr. Lyon Playfair before the members of the Royal Agricultural Society, in the year 1842, the subject of the lecture being, "The application of physiology to the rearing and breeding of cattle." He must confess that, as a farmer and breeder, he listened to that lecture at the time, as no doubt many others did, with a predisposition to set down everything as mere theory; but subsequent experience had convinced him that what the doctor said was true. Dr. Playfair set out by saying, "It would be presumptuous in any scientific man, however exalted his rank in science, to endeavour to instruct an assemblage such as this, or to recommend illustrations in the practice of an art which he has learned in the closet and not in the field." He must say that that was his feeling at the moment. "But it may be permitted," added the doctor, "even to the most humble cultivator of science, to examine the practice which you yourselves have perfected, and to point out the laws of nature upon which that practice depends." Dr. Playfair afterwards went on to tell them, in regard to warmth, that it was up to a certain point an equivalent for food. He said, "The average temperature of the bodies of our cattle is about 100 degrees, or more than 40 degrees higher than the ordinary temperature of this climate. Hence there must be some provision in the animal body to sustain the heat which is absolutely necessary for the performance of the organic functions. The air, being so much colder than the body, must constantly withdraw from it heat, and tend to lower its temperature. Whence, then, comes the fuel for the production of the heat?" What the doctor said was, in other words, that the heat required by the animal's body being 100 degrees, when the temperature was below that the exchanges were against the animal. If the bodily heat was only 60, it must be made up to 100 by fuel. What fuel? Why food. Surely, then, breeders ought, for the sake of economy, to keep up the animal heat. The doctor quoted Liebig in confirmation of his views. "Were we," said Liebig, "to go naked like certain savage tribes, or if in hunting and fishing we were exposed to the same degree of cold as the Samoyedes, we should be able with ease to consume ten pounds of flesh, and perhaps a dozen of tallow candles into the bargain, as warmly clad travellers have related with astonishment of these people. We should then also be able to take the same quantity of brandy or train-oil without bad effects, because the carbon and hydrogen of these substances would only suffice to keep up the equilibrium between the temperature of the external air and that of our bodies." Dr. Playfair himself afterwards said: "The only use of clothes, in the abstract, is to economize food. They assist in retaining the heat of the body, and render less food or fuel necessary for this purpose." To this he (the lecturer) would add another illustration. If a man who had led an active life, and had been accustomed to exposure to cold, retired from business, and confined himself almost entirely to a warm room, he would get fat, simply because there would be nothing to lower the animal heat. After the publication of Dr. Playfair's lecture, in 1842, a prize was offered by the Royal Agricultural Society for the best essay on the management of sheep. He was himself fortunate enough to be the successful competitor; and at the end of the essay, which was published in the eighth volume of the Society's Transactions, would be found the results of twenty experiments which he tried in animal-feeding, which confirmed Dr. Playfair's views in reference to warmth. He would not trouble them by entering into any of the details of the experiments, but he would observe that the experiments all hinged upon the relative value of the different kinds of food which were given to animals. For instance, there was a comparison between the common white turnip and the swede turnip. They all knew that the common white turnip contained a very large quantity of water. In September, while the sun was still powerful, he found that the sheep would thrive very well on a given quantity of that vegetable; but when the sun's rays had become more oblique, and the temperature of the atmosphere was considerably lower, so that as the animal inhaled the surrounding air the exchanges were against it, he found that the animals fed on the white turnip made no progress; the fact being that such food did nothing but just suffice to keep up the animal heat. At this period, however, that was about Christmas, came in the swede, which contained a smaller proportion of water. Less of this was required to keep up the bodily temperature, and with care on the part of the farmer, the animal went on pretty well till the spring, when there was no longer any difficulty. He might further observe, that he put eight sheep in summer into two pens, four in each pen, and besides giving them all clover, he supplied one pen with a pint of beans per day, and the other with a pint of peas. It might be supposed that there would be little difference between the two as the result of this variation of diet; whereas in fact, the sheep supplied with the peas did very well; while those that had the beans, like horses that were overfed with the same kind of food, soon exhibited symptoms of inflammation, the beans being too hot for the body at that period of the year. At the conclusion of his essay he said, "Thus, after many anxious reflections upon the '*principle*' which 'science' has dictated, "practice" has shown it to be one of great magnitude, and to develop the mysteries of past ages by pointing out those elements of the vegetable creation best adapted to Nature's laws under the varied temperature of the seasons."

While he advocated warmth, he was very far from saying that animals should be shut up in places where the atmosphere was at 100 degrees, or where there was no adequate provision for ventilation. What he wished to point out was, that warmth had an important and necessary connection with the food which was given to animals. Having now said enough with regard to the breeding of sheep, he would say a few words with regard to sheep required as food for man. There was no other animal so important in this point of view as the sheep. Mutton constituted the grand staple food of this country; and hence, as he had before remarked, the improvement of the breeds had a close connection with the increase of population. The Royal Agricultural Society and the Smithfield Club had both exerted themselves in the field of improvement, by offering prizes and holding exhibitions periodically; and great success had attended their efforts. Similar exhibitions had recently taken place in France; but the result thus far was that the English breeders and graziers who exhibited sheep swept away the prizes, and, pocketing the money, walked away with it (laughter). As regarded the distribution of the meat, some preferred early lamb, and others preferred saddle of mutton with a black foot, and had to pay for the luxury; while others, again, having less money to spare, made a different choice. The whole thing was beautifully arranged, and the culture harmonized well with the variety in the public demands. Having been at Smithfield market early on Monday morning, he had observed that the butchers from the West End had the first choice of the market; then came the purveyors for the mass of the middle classes; and, last of all, came those whose business lay chiefly with the working-classes, and who said they must have a great lot of meat for their money (laughter). A very remarkable alteration had taken place of late years with regard to the conveyance of sheep to market, and the return to the seller. When he was a lad, living in Lincolnshire, his father's sheep and capital were a fortnight walking to the metropolis, and they each lost eight or ten pounds' weight of meat on the way. Of course no one got the meat that was expended on the route—it was so much absolute waste. Now, sheep were conveyed from Lincolnshire to London in a few hours, and within thirty hours after they left the farm the animals were not only sold, but the farmer or dealer had his money for them, and could thus employ it at once. This was a very great improvement; in fact, one of the great facilities afforded by the railways. It was not necessary that he should say anything with regard to the dead meat markets, as they were all familiar with them. Here, again, however, was a comparatively new state of things. Meat was now brought from Scotland and other distant parts of the kingdom, which did not come formerly; and rapidly as people from various districts had located themselves in the metropolis, the supply of meat had followed them in the same ratio. The use of artificial manures had a close and interesting connection with this subject. By using such articles the farmer was enabled greatly to increase his growth of turnips, and before it was necessary for him to pay for the manures, he had an ample return in the extra quantity of sheep which he was thus enabled to keep and send to market. He must now conclude. He had told the commissioners that it was quite impossible for him, within a single lecture, to exhaust the whole question of the culture of sheep. The wool production he had not yet touched, and he believed it was to be entered upon by a gentleman from the North of England familiar with manufactures, who would take up the subject where he (Mr. Smith) had left it. The wool collection in the museum was by no means complete; and as he had before intimated, he should, after his return home, do everything that might be in his power to supply the defects. The great importance of sheep, in relation to their wool-bearing properties, was daily increasing. Beyond our own growth the imports of wool from Australia, in 1807, amounted to only 245lbs.; whereas in 1855, the latest period up to which the returns extended, the importation was 40,810,137lbs. In 1833 we received from India 3,721lbs., in 1855 4,594,520lbs. The total imports of wool from all places, in 1855, amounted to 99,300,446lbs.

The lecture occupied one hour and three-quarters, the whole of which being given from notes, made it the more interesting to the audience. The lecturer concluded by thanking the audience for the patience with which they had listened to him, and on retiring he was loudly cheered.

ON PIGGERIES.

Swine are filthy animals in the cleanest condition in which they can be kept, and emit an offensive smell that is very disagreeable to other animals, as to cattle, with which the nearest association is placed in the arrangement of being reared and fattened. The manufactory of pigs is best located in a separate position from the farmery, but closely adjoining it, as the purposes are combined, and require a juxtaposition of utensils with which to work in unison. The site of the farmery, and the elevation of ground, will very much dispose the arrangements. The piggery may stand in the front range of either wing, in a small distance removed, and with an open front to the most benign aspect. The walls of the erection being low, the position in front of the farmery will not much exclude the sun from shining on the farm-yard behind, and a space of twenty or thirty yards being intervened between the piggery and the front of the farmery, no inconvenience will happen from the respective situations. As in all cases of the kind, circumstances will direct the arrangements.

The exterior shape of the piggery is best in a long square, differing in a third or fourth from the true equality of sides. The shortest sides are placed to form the back part and open front, the former being divided into a cooking-house, and sheds for the boar and brood sows; the extent being always proportioned to the size of the farm, and the number of swine that can be kept. An end door in the food-house affords a passage along the front of the breeding sties, and a ready access with food and litter. A front door in the centre of the house leads along a paved road between two rows of feeding sties, in which the bacon hogs are confined, in two together, and provided with sty and shelter-shed of the area of about 100 square feet. A light four-wheeled waggon of thin iron carries the food along the passage, and the swine are fed on the right and left with much convenience and facility. The two rows of sties, and a centre passage in width, occupy the length of the food-house on large farms; on less extents, one row of sties will be placed, and an end-door will serve the feeding and breeding departments. The front of the breeding sties in width, the short side of the piggery, minus the length

of the cooking house, extends to the open front of the whole erection, and forms a yard for store pigs, from the age of being weaned, till drawn into the feeding sties, according to the forward condition. Shelter sheds are placed along the side-wall of the store-yard, and low in the roof, in order to preserve warmth, that is so essential to the welfare of swine. The young pigs are placed in this yard immediately on being weaned, are fed for a time with wheys and milks, mixed with meals, and gradually entered into the food of vetches and clovers during summer, and raw potatoes and turnips during the winter. Ample litter of straws and chaffs is supplied to this yard, and the best is the strawy litter from the stables, which being warm in the dung of the horse, supplies warmth to the pigs; and being mixed with their saponaceous excrement, a manure of great value is formed. The refuse of the green vetches and clovers adds to the mixture in the varied composition. In this yard is shown the great value of swine, as manufacturers of manure. The green food of summer, in clovers and vetches, induces a large discharge of urine, which impregnates and renders soluble the woody fibre of the refused stems, and the straws that are used as litter; the cold saponaceous excrement is mixed with the warm fæces of the horse; while the noses of the animals being constantly employed in searching for food among the litter, turn over and mix the whole mass of substances in a very beneficial manner for the purpose of a vegetable compost. The yard must be frequently covered with litter, and thinly and evenly spread: the different substances must be mixed in the layers, in order to produce a similarity of composition and condition in the mass when it is carried to the manure heap in the fields, and placed in the layers of alternate qualities. This attention is necessary to every preparation of manure in the farm-yards—a level surface, frequent coverings with litter, thinly and evenly spread, and a thorough impregnation of every part with the urinary moisture of the animals. If any part is seen to be too dry, it must be laid level, and covered with moist substances; if too wet, the dry litter of the stable must be strewed over the place, and each part of every yard must be thoroughly treated with moisture in the proper quantity. A regular attention will prevent any deviations from this essential rule.

The season of curing bacon extends from October to the end of March, and during that time there may be preserved two fattenings of hogs in succession. The pigs in the store-yard, that are of the proper age and most forward in condition, are placed in the feeding-sties, in two together, by the first of October, and will be ready in the beginning of January: a second lot is drawn into the sties from the store-yard, and will be ready in March, which concludes the season of curing. The management after that time is wholly in the breeding-sties and store-yards. Brood sows are best restricted to two litters of pigs in a year, and an average of eight in a brood will afford a full supply of animals to be manufactured. More litters may be got in a year, but the vigour of the pigs becomes puny, and the sow is much exhausted by the severe employment of suckling. A less frequent propagation produces a more vigorous progeny; and not only in swine, but in every animal whatever; and if the system were adopted pursued, the result might wholly reproduce the animal organization.

It has been very satisfactorily ascertained that swine are benefited by cooked food in a very large degree; while other animals, as horses and cattle, show a promotion that does not compensate the labour of preparation. The physical constitution of the pig, and its delicate intestines, may account for this differential benefit. Bacon pigs are fed twice a-day, by break of morning, and in the early evening before sunset, with cooked food, in steamed potatoes mixed with meals of any kind, moderately thickened, and given in a milk-warm condition. This preparation is done in the food-house before-mentioned, which contains the steaming apparatus and the meals in readiness. It is two storeys high, and the second floor is dry for the meals, which are kept there for use. The daily allowance to the pigs is ample to the full satisfaction, but none to remain in the troughs to become cold, and produce a nauseating effect. The quantity the animals can daily consume is soon ascertained, and regulated accordingly. During the last month of fattening, one daily meal is given of uncrushed grains, as oats and barley, and especially of beans, which contain the tannin principle, and impart a muscular firmness to the flesh, and the whiteness that so much recommends the quality of the bacon. This firmness is a chief point by which the flesh is judged.

Brood sows are constantly fed with liquid substances, as milks and wheys mixed with meals, which promote the secretion of milk for the hard task of suckling. Dry food for a time, after the pigs are withdrawn, much encourages the salacity. Weaned pigs are treated for a time with warm gruels of meals and milk—thin and warm at first, then gradually thickened and used lukewarm into a cold condition, when the animal becomes a gradual consumer of clovers and vetches, and raw food.

It is very advantageous that a few small pigs from weaning have the liberty of wandering over the feeding-yards at pleasure, and to sleep and nestle in some chosen corner. A hole in the lower part of the gates lets the animals in and out the yards, in which they eat the crumbles of the turnips, and search for pickles of grain among the straws of litter. The surface of the yards is turned and tossed about by search with the noses, and a beneficial mixture is effected of the different substances. Pigs, in a limited number, are brought forward in this way in a very fresh condition for the feeding sties, and when assisted with light grains laid on dry ground, the full fattening is done as well as in fattening cribs. The meat may not be so large in quantity, but the quality is superior both in texture and firmness.

The mode of rearing and feeding swine now detailed may be done on any farm according to the extent, from one brood-sow to four, which will afford fifteen to sixty pigs yearly. The intervening numbers will fill the different extents of occupation. Every method must be systematic—large or small, the performance must be regular and orderly, with a constant adhesion to the rules that are adopted. The buildings must be provided, and the food allotted; the care must be bestowed, and the attention unceasing. From want of systematic regulations, there constantly happens desultory and languid performances, which fail to produce any valuable results, and sink into weak and unprofitable establishments. Swine yield more flesh from the food consumed than any other fattened beast: the quality is very nutritious: it takes the salt more readily than any other flesh, and, from the smaller quantity required on that account, the cured article is not so salt in the use as other flesh from animals. It enters very largely into the consumption of naval stores, and for domestic use the flesh is very extensively entertained both in a fresh and cured condition. No other animal food enters so largely into general consumption; yet in some few cases only has the manufactory of the flesh been reduced into system, as with sheep and cattle—food is grudged, and attention withheld, and the animals wander about the farmery despised and unvalued. No farm is established without an arrangement for swine, than which no animal will yield so much flesh for the food consumed, or is fattened with so little cost. J. D.

THE USES OF A DEAD HORSE.

The first, or introductory lecture on the Commercial Products of the Animal kingdom, in course of delivery at the South Kensington Museum, was delivered by Professor R. Owen, who gave a *resumé* of the economic uses of animals generally to man, interspersed with much interesting information on anatomy and physiology, in that pleasant and popular style for which he is characteristic.

The second lecture was delivered on the 25th Feb., by Dr. Lyon Playfair, C.B., on the use of refuse animal matter; and it is this address to which we would chiefly call attention, as affording much curious detail. Taking as his text, the uses and value of a dead horse, the lecturer went over the whole range of seemingly waste products, detailing their processes of re-conversion, comparative value, and resulting products; thus proving that if we but follow the example of Nature, all substances, however apparently noxious and useless, are re-convertible into other and very important commercial products.

We shall confine ourselves, in the present instance however, to his main illustration—the carcase of a dead horse.

What the mortality may be of the equine race in the United Kingdom we have no means of ascertaining. Indeed, we have no correct data for estimating very precisely even the total number of horses in the United Kingdom. We have returns for Ireland and Scotland, and the agricultural statistics for these countries for 1856, gives the number at 753,170. Those in England and Wales must be guessed at. Sixteen or seventeen years ago Mr. M'Culloch estimated the number of horses in Great Britain at 1,400,000 to 1,500,000. Now this guess must have been somewhat wide of the mark, for there are scarcely more than this in the whole kingdom at the present time, at least judging from the most careful calculations.

Three or four years ago Mr. Braithwaite Poole, in his "Statistics of British Commerce," took some pains to arrive at the true figures; and his estimate, based upon parliamentary returns and carefully-conducted enquiries, brought out the numbers at about one million and a-half, classified as follows:—

Paying duty (of which 1,530 were race-horses)	320,982
Exempt from duty	413,028
Partly exempt from duty	77,827
Horses in Ireland	488,908
Young horses, ponies, &c., &c.—Scotland and Wales	200,000
	1,500,745

Now this is much below the number at the present time; for in 1847 the number of adult horses in the United Kingdom was given at 805,458, of brood-mares 4,246, and of horses used in husbandry 900,000; and a parliamentary return of 1854 showed that there were 432,746 horses paying duty. We have also, of late years been importing largely from the continent—especially from France and Belgium. For the four years, ending with 1856, we received 18,293 horses from the Continent.

With the large traffic carried on in the metropolis by omnibuses, cabs, pleasure horses, brewers, carriers, travellers, and other draught animals, the numbers in London must be very considerable. There are at least 7,000 public conveyances plying for hire, and the omnibuses alone employ about 13,000 horses. The number of vehicles passing along the principal thoroughfares in an ordinary day of twelve hours, is about 126,000.

Having dealt with the statistics of living animals, let us now look to the commercial products of the dead horse. From 250 to 300 horses die weekly within a radius of five miles from Charing Cross, and the flesh of these is chiefly consumed by dogs and cats within that area.

Firstly, then, we have the hair, which may weigh about 1½lb., and which sells for 8d. to 1s. Horse-hair we know is applied to many purposes; it is made into hair-cloth for seatings, coloured hair damasks, bags for crushing seed for the use of the oil-crusher, cider-makers, and others. A consumption of 800 tons of horse-hair a-year, of home and foreign production, valued at about £80,000, shows the value of this one item.

Next we have the hide, weighing—say 30lbs., and worth possibly 8s., for converting, when split, into the finest Cordova leather; or, in its full thickness, for covering the large board-room tables of offices, &c.

The tendons weigh probably 6lbs., and are converted, like other animal tissues, into fine glue, or gelatine.

The flesh will weigh about 224lbs. boiled, and may be used as meat for men, dogs, poultry, &c.

Smile not, gentle reader, at the banquet offered—of viands which are just now in high repute on the continent. A society of economists, naturalists, and hardy gourmands in Paris, aim at the introduction of horse-flesh in the category of butcher's meat. They set the example themselves, and this example is spreading. It is argued that the horse ought to contribute to the nourishment of the human race, as well as the ox, the sheep, and the pig. That it does so already in our own metropolis to a great extent, in the shape of nominal smoked "ox-tongues" from Russia, and chopped so-called "beef" sausage-meat in Westminster, Whitechapel, and other suburban localities. But the penchant for roast and boiled horse-flesh has found adherents even here, and our esteemed contemporary, the "Journal of Agriculture," of Edinburgh, has come out strong in a recent number in its favour.

M. St. Hilaire, the champion of this new addition to our food resources, reasons in this fashion—

"Horseflesh has long been regarded as of a sweetish disagreeable taste, very tough, and not to be eaten without difficulty. So many different facts are opposed to this prejudice, that it is impossible not to recognize its slight foundation. The free or wild horse is hunted as game in all parts of the world where it exists—Asia, Africa, and America—and formerly, and perhaps even now, in Europe. The domestic horse itself is made use of as alimentary as well as auxiliary—in some cases altogether alimentary—in Africa, America, Asia, and in some parts of Europe.

"Its flesh is relished by people the most different in their manner of life, and of races the most diverse—negro, Mongol, Malay, American, Caucasian. It was much esteemed up to the eighth century among the ancestors of some of the greatest nations of western Europe, who had it in general use, and gave it up with regret. Soldiers to whom it has been served out, and people in towns who have bought it in markets, have frequently taken it for beef. Still more often, and indeed habitually, it has been sold in restaurants, even in the best, as venison, and without the customers ever suspecting the fraud or complaining of it.

"And, further, if horseflesh has been often accepted as good

under a false name, it has also been pronounced good by those who, to judge of its qualities, have submitted it to careful experiment, and by all who have tasted it in proper condition—that is, when taken from a sound and rested horse, and kept sufficiently long. It is then excellent roasted; and if it be not so acceptable as *bouilli*, it is precisely because it furnishes one of the best soups—*perhaps the best* that is known. It is good also, as experiments prove, made by myself as well as others, when taken from old horses, not fattened, whose age was sixteen, nineteen, twenty, and even twenty-three years—animals thought worth no more than a few francs beyond the value of their skin. This is a capital fact, since it shows the possibility of utilizing a second time, for their flesh, horses which have already been utilized up to old age for their strength; and, consequently, of obtaining a further and almost gratuitous profit at the end of their life, after they had well-nigh paid the cost of their rearing and keep by their labour."

So much for the great champion of horseflesh.

Having disposed of the flesh, we come next to the blood, heart, and tongue, weighing about 60lbs. The former is used, like the blood of other animals, as a decolorizer, for manure, and for making, with other animal substances, the well-known salt, prussiate of potash. The disposal of the heart and tongue we will say nothing about, as there is somewhat of mystery resting upon their appropriation.

The intestines of the horse, weighing about 80lbs., are converted to several uses. When cleaned, they serve for covering polonies and sausages; or they are twisted into bands or strings for bowing cotton, or for other purposes.

There is seldom much fat to be got from the horse: probably about 20lbs. may be obtained; and this is used, after being distilled, for burning in lamps. We import horse grease largely from the River Plate, but we get better at home. The grease is also worked up by the soap and candle makers in common with other fats, while the entrails and remnants are given to hogs, to make food for home consumption—at least this is so in the United States, where the porcine race are less daintily fed than our own store-fed pigs.

The bones come next; and these weigh, say about 160lbs., and are sold at the rate of 4s. 6d. per cwt., either to convert into knife-handles, or for making phosphorus, and superphosphate of lime. They will not do for animal charcoal, because horses being usually killed when aged, the bones contain too great a proportion of phosphate of lime, and too little animal matter. Ground into dust, or crushed into half-inch bone, they make excellent manure; while other special manures for turnips, &c., are made from the blood, flesh, and bones combined.

The Kensington Museum catalogue, compiled by Mr. P. L. Simmonds, lets us into the secret of a ready way of cleaning the bones and divesting them of putrid flesh, &c., so as to fit them for use in manufactures. To take off the flesh by hand is a tedious and difficult operation. An ingenious Frenchman solved the difficulty. He noticed that rats were very fond of horseflesh; so are fowls—other arguments in favour of M. St. Hilaire's reasoning of the wholesomeness of the food. Our Frenchman advised the authorities to colonize the dead horse-pound with rats. This common pound is an enclosed area of about ten acres, surrounded by a stone wall, to which all carcases, &c. are taken, and among the rest the 400 horses which die or are killed in a week in Paris. The catacombs furnished rats by thousands; and now a dead horse put in over night is picked beautifully clean by the morning, and the bones are ready for the bone-dealer. A grand battue is also periodically made, to keep under the rats, and they are utilized by making their skins into gloves, and possibly their flesh into pies or ragouts. We have nearly done with the economic uses of our worn-out hack; there remain but his pedal extremities to deal with. The hoofs, weighing about 6 lbs., are worth 8s. to 10s. per cwt. for gelatine, or for making prussiates. They are not adapted to pressing into the, so-called horn buttons, which are made from ox-hoofs, but possibly may turn up polished in the shape of a snuff-box, capped with silver. The shoes will work up into shoes again, or sell for old iron; and the nails are much esteemed for making gun barrels.

We have now used up our "old horse," and this is merely the example of many other animals whose carcases are turned or might be turned to various useful purposes. Such a history points a moral that nothing should be despised, for out of many waste substances money is to be made; and the large profits of scavengers, knackers, and dust-contractors are evidences of the utilization of offal and sweepings.

FURZE AS FOOD FOR HORSES.

Sir,—As you now and then receive some little matters written by me, and are so courteous as to give them a place in the *Farmers' Gazette*, I now send another, in the hope it may promote your object in being of benefit to those who read your paper. It has been too much the practice of horticulturists to introduce and recommend new plants and flowers, and to let the old pass into oblivion. Thus the beautiful moss-rose, the cabbage-rose, the York and Lancaster, the double white-rocket, with others, which fifty years since were the delight of the cultivators, some are now never seen, and others, like poor relations, are left to take the lowest room, and new or scarce plants and flowers, which bear no comparison in fragrance or beauty, are the ornaments of the garden. In the same way, in improved agriculture—though there are few who join more in heart and hand in the introduction of new plants and new practices to this land—though there are many of the old I long to see exploded, such as poorly-paid, badly-fed, and, as a certain consequence, badly executed labour, small, weak, badly-fed horses, and consequently light and inefficient ploughing, and therefore scanty produce—still there are others of the old school I regret to see neglected—

"'Tis right to be off with the old love,
Before we are on with the new."

I shall now make some remarks on the most valuable of those old practices which are too much neglected—feeding cows and horses on furze (whins), the fiorin grass, and irrigation. I have been for fifty years and more feeding my cows and horses on furze; and I can say, from that long experience, that it is the cheapest and the best food for the autumn and winter months. I saw it in constant use at the residence of the late Rev. Horatio Townsend, the author of the statistical survey of this county, who strongly recommended it. I followed his example, and never have regretted doing so. I have had my horses, getting neither hay or oats, in more beautiful condition (sleek as mice) than any of my neighbours, though they had costly grooms, the horses fed with best hay, oats, and beans, and warmly clad. Mine were, perhaps, not as fit for the race-course or the hunting-fields; but for road-riding, carriage-work, or the work of the land, they were most fit, although fed only on chopped furze and steamed swede turnips; and I rejoice to see that this valuable food has been brought under the notice of the agriculturists.

On arranging some papers lately, I found a letter, dated June, 1840, from one of the best practical agriculturists I know. He states, "The most profitable crop I have planted is furze. With an acre and-a-half I fed five horses up to the

first of June. I have twelve tons of hay for sale, which I never had before. It would be much easier to induce the farmer to cultivate furze than to grow turnip; and I believe it is more profitable. Land inaccessible to the plough, of which we see so great a proportion, would yield great crops of furze; and land remote from manure could not be better disposed of. We are in the infancy of knowledge as to what ground is capable of, or what plants are best suited to the varieties of soils. The florin is a plant that never got a fair trial in the south of Ireland. I think the time will come when all the bog and low lands will be covered with it. If you look out about the latter end of June you will meet it at every step." The old practice of preparing furze was tedious, and comparatively expensive—by a block with transverse knives, sometimes with a long handle, and better with a chain, hooked on what is known by the name of a turner wattle, or by a straight spade, sometimes by thrashing. The great desideratum has been hit upon by Messrs. Richmond and Chandler, in their powerful straw-cutters, varying in price from £7 to £10.

I have just now attended my machine bought from Mr. Thomas M'Kenzie, Cork, for £7, a man cutting, and a boy feeding it, the furze ready, and in 17 minutes they cut 17 buckets full. The bushel contains 3½ gallons. This is fully sufficient for four horses for 24 hours instead of hay; hay is spread on the top of the furze, and cut with it; it improves the cutting, saves the boy's hands from the prickles, and is an advantage in the feeding. When ready it is wetted with water, which makes the mastication easier. The expense of the man and boy is 1s. 5d. a day—say 10 working hours, and working little once a quarter-hour or [the one-fortieth of 17 pence for the labour of preparing food for four horses, or about three-eighths of a penny a-head. A tenant of mine who lives in Carberry told me he feeds his horses entirely, and his cows mostly, on it all autumn and winter; he mows it every second year, and has abundance for them from a piece of land which cannot be ploughed, and which would produce nothing else; he cuts it with the straight spade, and it takes a man for the entire day to prepare sufficient for six horses. Now that Richmond and Chandler have brought out such a machine, there is no excuse for it not being in general use; and though furze will grow well on stony and rocky land (I have seen the roots several feet down in the chinks of a quarry), the best arable dry land will produce a far better and more abundant crop, and a more succulent shoot. Three acres of such land appropriated to the growing of a plant which is perennial, and requires no further culture (though, I doubt not, it would be still better for annually opening the ground and digging or forking in manure), still an everlasting winter meadow, of no comparison better food than hay, is no slight benefit now that the difficulty of its preparation—the great obstacle—has been overcome. Cattle will not hove with it. They are always sleek, an indication of health. It is in a fit state from October to May, inclusive. It improves the wind; a thick-winded horse becomes a free breather; broken-winded have no appearance of their being so; and I have seen horses cured of cough by feeding with it. I dare say many who know not its value, and who are of those who deprecate any innovation or change, will say all this is hyperbole; this was often said of florin and of turnip culture; but when the failure of the potato compelled turnip culture, they then saw that the new was better; and I pledge myself that any who henceforth use furze, as directed, will fully agree in every word I say. Directions for sowing the seed in fields would be very desirable.

Yours, &c., WILLIAM R. TOWNSEND,
Aghadda Rectory, Rostellan,
Co. Cork, Feb. 12, 1858.

ON THE ACTION OF NODULES OF PHOSPHATE OF LIME ON VEGETATION IN GRANITIC AND SCHISTOSE SOILS.

[TRANSLATED FROM THE FRENCH OF THE "JOURNAL D'AGRICULTURE PRATIQUE."]

In according its kind approbation to my last researches on the solubility of fossil phosphates of lime, and in deigning to encourage me, through the organ of its reporter, M. Payen, to follow them up, the Academy of Sciences has marked out for me a course in which I have proceeded with the anxious desire of noticing in it some facts interesting both to physiology and to agriculture. I propose to detail the first results to which my experiments have conducted me.

I was desirous, in the first instance, in spite of the unfavourable season, to make in May some preliminary essays on the culture of wheat. For that purpose I commenced operations upon a piece of land cleared only a few days previous to the experiment, and on which I have comparatively employed nodules of pulverized phosphates at the rate of 55 per cent., and animal charcoal (black) in small grains, 72 per cent. of richness. The earth, rich in humus and acid principles, possessed the best conditions for dissolving the phosphates. The dressing was employed at the rate of 6 hectolitres to the hectare, and the results observed were as follow:—

In the pieces which were planted with wheat there was no appreciable difference between the produce of the animal charcoal, the fossil phosphates slightly animalized, and the same phosphate mixed with very porous charcoal. There was a very marked superiority, which I was far from expecting, in another piece in which the nodules, simply reduced to very fine powder, had been employed comparatively with animal charcoal in small grains. In all these essays in other respects the produce was moderate, whatever was the dressing adopted, in consequence of the very recent clearing of the land.

Two pieces of land were sown with oats, and dressed, one with powdered nodule, the other with animal charcoal. In both cases the produce was fine, but there was still no appreciable difference observable, either in quantity or in the appearance of the crops.

In spite of the unfavourable conditions in which these preliminary essays took place, I must confess I was struck with surprise on seeing my anticipations at fault in regard to the action of the fossil phosphates *employed alone, and in the state of fine powder.* My researches in the laboratory on some coefficients of solubility in carbonic acids, the laws of analogy, and, I must also add, the ignorance of actual science as to the modifications the nodules undergo in presence of the air contained in the arable soil—all this led me to regard these manures as slowly assimilable, deserving on this account to be classed far enough from bone charcoal. Nevertheless the agricultural experiments seemed to contradict my preconceived ideas. We shall see, as we proceed, that this contradiction manifested itself afresh in more conclusive essays.

My second series of experiments were made on the culture of buckwheat, which in the west absorbs enormous masses of animal charcoal. The surplus of the quantities assimilated by this plant remain in the soil, in which its action is subsequently felt upon the winter wheats.

In order to place myself as much as possible beyond the influences, multiplied and unequal, of experiments on a large scale, I resolved to make my experiments in pots, on substances exactly weighed, and in presence of elements of irrigation and exposure perfectly identical.

Eleven pots were filled with earth extremely poor, and derived from the disintegration of schistose rocks. The earth was minutely mixed in each pot with 10 grammes of manure and two seeds of buckwheat, which were sown from the 25th of June to the 22nd of September, when the experiment was completed. The watering of the pots was performed twice a-day with rain water. Vegetation proceeded well, except in the cases in which earth was used without manure, and with nodules treated with 20 per cent. of sulphuric acid. In these two instances the plants were poor and weak, and the produce insignificant. We must not forget that the poverty of the earth employed was extreme. Humus existed in it only in very minute proportion. Its aptitude to retain water and condense the gases was as feeble as possible.

At the end of three weeks, it was easy to perceive the favourable effect of the phosphoric acid upon the buckwheat. Where the superphosphate of lime, of animalized phosphates, and of the mixture of blood and powdered nodules were used, the vegetation was both luxuriant and precocious. The animal charcoal was distanced, and owing to the poverty of the earth the pure phosphate of lime gave wretched results. The following, however, is the complete summary of the observations, made with the greatest care:—

RESULTS OF THE CULTURE OF BUCKWHEAT IN A SCHISTOSE EARTH, DESTITUTE OF HUMUS, AND IN PRESENCE OF A QUANTITY OF PHOSPHORIC ACID EXCEEDING THE REQUIREMENTS OF THE CROPS.

THE KIND OF MANURE USED.	DRY GRAIN HARVESTED.	DRY STRAW HARVESTED.	TOTAL RESULT.	HEIGHT OF THE PLANT.	NUMBER OF GRAINS.	OBSERVATIONS.
	Grammes.	Grammes.	Grammes.	M.		
Fossil phosphate in large grains, containing 54 per cent. of phosphate of lime	0.363	1.280	1.648	0.30	18	—
Phosphate in fine powder	0.462	1.458	1.920	0.56	34	—
Phosphate mixed with vegetable charcoal and very weakly animalized	1.282	1.810	3.090	0.50	111	—
Phosphate mixed with dried blood and containing 5 per cent. of azote	1.693	2.190	3.883	0.44	137	—
Phosphate treated with 20 per cent. of sulphuric acid neutralized with chalk	0.020	0.870	0.890	0.27	2	abortive
Phosphate treated with hydrochloric acid	0.547	0.790	1.337	0.30	33	—
Pure regenerated phosphates of the nodules	0.630	0.700	1.330	0.30	40	—
Charcoal from the sugar refiners, 67 per cent. of phosphate, and 1 per cent. of azote	0.970	0.893	1.863	0.23	64	—
Charcoal from the gelatine factories, 83 per cent. of phosphate, and 5 per cent. of carbon	0.212	0.375	0.587	0.29	18	shrivelled
Guano from the Caribbees, 74 per cent. of phosphate, and four-thousandths of azote	0.703	0.843	1.548	0.35	45	—
Poor earth without manure	0.040	0.724	0.764	0.27	4	abortive

In examining these figures it is important to state that they clear up a particular point of the question, without constituting on that account a scale of return applicable to the condition of an extensive cultivation. Indeed it is very evident that the impulsive action produced by the azote was not applied here to the phosphate of the animal charcoal as to that of the nodules mixed with blood. I would, however, remark that the experiment No. 3, the results of which are very fine, were produced under the influence of weak doses of animal substances. Had the porous vegetable charcoal in this case a condensing action immediately utilized? It appears very probable.

Let it therefore be well understood that the figures expressed in this table are applicable only to the special circumstances of the experiment, and it is requisite, in order to study more completely the action of the nodules, to make new essays in which the organic matter of the soil determined will perform a part which is wanting here. Under these reserves I think I am able to establish the following facts:—

1. The nodules of phosphate of lime of the Ardennes, reduced to fine powder, and exposed some months to the air, are assimilable by vegetables.

2. Their favourable action on granitic and schistose soils, in the clearings of lands and heaths, may be variable according as we employ them alone or associated with organic substances.

3. As this is also remarked in the employment of the phosphates of charcoal of clarification, and charcoal powder of the filters, there is agreement sometimes in associating organic substances with the nodules in fertilizing poor soils by dissolvent agents, and sometimes, on the contrary, in employing them alone on clearings in which vegetable substances abound.

4. The addition of blood to the powdered nodules gave excellent results in the triple point of view, of return in grain, of vigour of the straw, and of precocity.

5. The employment of the action of acids, in order to promote the assimilation of phosphates, will only take place *in lands and cultures in which the superphosphate is actually found useful by the agriculturists.* In all cases, on the contrary, in which bone-black in grains is rapidly dissolved, the nodules finely powdered will themselves be assimilated.*

6. Lastly, and as a consequence useful to point out, it is once more established that from the search for co-efficients of solubility in the laboratory, to the agricultural verification, there is all the distance that separates an extremely simple effect from one extremely complex.

ADOLPHE BOBIERRE.

BATH AND WEST OF ENGLAND SOCIETY.

A Monthly Council was held on Saturday, Feb. 27, at Waghorn's Hotel, Taunton, John Sillifant, Esq., in the chair.

THE CARDIFF MEETING.—Mr. Widdicombe (Director), brought up a report on the subject of the tenders received from the various contractors for the erection of the hoarding, for the show-yard, offices, and works for the meeting at Cardiff in June next. The tender of Mr. George Pollard, builder, of Taunton, was accepted. The report of the committee (under the guidance of Mr. Gooch, the consulting engineer of the society), on the terms upon which steam-engines would be permitted to exhibit in the show-yard, was introduced and discussed. The report was adopted, and ordered to be printed and circulated among intending exhibitors in this department.

THE MEETING IN 1859.—The deputation appointed to visit Barnstaple reported that they went to that town on Thursday last, and inspected three sites offered for the exhibition next year. They now recommended a piece of land about a mile from the Barnstaple Station, on the North Devon Railway, in every way suitable, provided the requirements of the society were complied with. It was also reported that eligible fields for the trial of implements would be offered to the council on advantageous terms.

NEW MEMBERS.—The following new members were elected:—

Mr. R. F. Jenner, Winvoe Castle, Cardiff
Mr. Blackburrow, Tower Head, Banwell
Mr. N. Cook, Ayshford Court, Somerset
Mr. F. T. Allen, West Kington, near Chippenham
Mr. J. Spurway, Spring Grove, Milverton
Mr. J. P. Spurway, Spring Grove, Milverton
Capt. F. Spurway, 2nd Somerset Militia.

---

* This is, on the whole, what practice has already demonstrated in the last harvest with the greatest clearness.

MR. POPPY OF WITNESHAM.

RESPECTED FRIEND,—Herewith I send thee an extract from the *Suffolk Chronicle*, giving a brief outline of the life and labours of our valued old friend and father of farmers' clubs, Charles Poppy—thinking it probable it would be interesting to the readers of the *Mark Lane Express*, some few of whom, who were readers of the agricultural periodicals sixty years since, will probably recollect his early efforts to promote the practical interests of agriculture. To him we owe in this district the earliest introduction of swede turnips, as of a crop of mangel wurzel, and of Belgian white carrots; the most successful prevention of the ravages of the turnip fly; the invention of the scarifier, which was the original type of those now in use; and the introduction of the system of farmers' clubs. Well do I recollect visiting, in company with my highly-esteemed friend, John Morton, one of the monthly meetings of the primitive club, held in the long low-room of the village inn at Ashbocking, when, seated as president at the end of a long table, covered with gigantic roots, interspersed with glasses of steaming mixture, and pipes with well-waxed ends, he gave us, in his own genial and unobtrusive manner, interesting anecdotes of his successes and his failures, of his temporary discouragements and his ultimate rejoicing in the triumph of successful attainment. At a shortly subsequent period, two or three of those warmly interested in agriculture in the neighbourhood of Yoxford visited the Ashbocking Club, and the rapid establishment of similar clubs in Yoxford, Halesworth, Beccles, Wrentham, Harleston, Framlingham, and Wickham Market, was the result. Through the kindness of the editors of the *Mark Lane Express* the reports of the proceedings of these various little societies were published, and the practical usefulness of their discussions thus obtaining wide circulation, institutions of a similar character were speedily formed throughout the length and breadth of the land.

About this time, the late William Shaw with two or three of his friends, conceived the idea of centralizing these by the establishment of a club in London, and hence the commencement of the Central Farmers' Club.

Surely amongst the thousands who have through so long a period benefited by the disinterested labours and researches in which he has spent his long and useful life, there must be many who will rejoice in the opportunity to contribute to the promotion of his comforts and that of his aged partner for the few remaining years that may yet be allotted to him, now that the day of his working for others —at the age of 85—is well nigh passed.

His old friend and co-worker for nearly 50 years, Arthur Biddell, of Playford, has organized the plan of obtaining sufficient funds for the purchase of an annuity on the joint lives of the worthy pair; and if thou couldst suggest that subscriptions should be received at the office of the Central Farmers' Club, there is little doubt the object would be speedily accomplished.

With kind regards and pleasant memories of other days,
I remain, my dear friend, sincerely thine,

Ipswich, 2nd Month 22. J. ALLEN RANSOME.

SUFFOLK WORTHIES AND PERSONS OF NOTE IN EAST ANGLIA.

CHARLES POPPY, THE AGRICULTURIST.

Among the many men in Suffolk who have achieved a name and reputation by the practice of agriculture, few could be mentioned who have so deservedly won a claim for distinction among Suffolk farmers as Charles Poppy, of Witnesham. This venerable agriculturist, the correspondent and contemporary of Arthur Young, Sir John Sinclair, George Webb Hall, and others—a man whose numerous experiments and lengthened experience on the crops and soils of this district render him pre-eminent among the occupiers of land in Suffolk—is justly entitled to a niche in the temple of agricultural fame.

Charles Poppy was born in the parish of Withersfield, in the year 1773. At eight years of age he was sent to be educated at Tilney School, Harleston, Norfolk, where he remained seven years. Thomas Pallant, the meteorologist, was a schoolfellow of his. When he left school he was placed with Mr. Candler, of Linstead, near Halesworth, for instruction in farming. There he profited but little, for his master was not a strict one, and, as many of Charles's schoolfellows lived in the neighbourhood, he had the run of many farms; and this suited a mettled lad of his age better than work. It was a dairy farm, and he remained there two or three years. Candler was a regular old-fashioned farmer, but hearing that a new-fangled system of draining had been tried on a farm at Cookley, he took his agricultural pupil with him to look at it out of curiosity, and here it was that our future experimentalist saw, for the first time, an arable field of six or eight acres subjected to the system of *thorough* drainage.

From Mr. Candler's he went to "Frendze Hall Farm," Scole, Norfolk, an arable and grazing farm of upwards of four hundred acres. There he remained four years, and there he learnt to work. There it was that he made the acquaintance of Mr. Kent, who was steward to George the Third, which led to an interchange of correspondence upon agricultural subjects. There it was that he first saw Swede turnips grown. Thomas Avis, Esq., steward to the Duke of Norfolk, occupied the farm adjoining "Frendze Hall," and he was at that time trying to grow swedes, the root being then unknown in the East Anglian district. Mr. Avis raised them in his garden and then planted them out, and he continued this practice for several years.

As the fourth year drew to a close our young farmer began to feel himself able to practise the art of agriculture, and he therefore engaged himself as assistant to Mr. Wythe, a land valuer and agent at Eye, who occupied the "Park Farm," and two others in the immediate neighbourhood. Having procured some seed from his old neighbour in Norfolk, Mr. Avis, he proceeded to try the experiment of growing swedes. There was a bailiff at the farm, but such scarce and valuable seed he could not trust in other hands than his own, and he therefore sowed it himself. This was the first known instance of Swede turnips being sown for a crop in Suffolk. The seed, however, was put in too late, and the crop proved very poor, too small to feed cattle, lest they should choke themselves; in fact, they were like Bloomfield's description of the rinds of Suffolk cheese:

"Too big to swallow, and too hard to bite."

After remaining four years with Mr. Wythe, he resolved upon farming on his own account. He took a farm at Occold; but at the end of three years the owner wanted it, and Mr. Poppy had to quit. He then entered into the seed business, and travelled over Suffolk, Norfolk, and part of Cambridgeshire. Being a keen observer, his travelling gave him a good opportunity of making himself acquainted with the soil, culture, and vegetable productions of the districts he visited, and this he did not lose sight of. The line of life, however, did not please him, and before the end of twelvemonths he was again engaged by Mr. Wythe to undertake the sole management of his farms, that gentleman having removed to West Norfolk.

Mr. Poppy, desirous of being on his own footing, next took a farm at Wetherden. Here a new phase of life opened to him. He married Frances, the youngest daughter of the Rev. John Gibbs, rector of Occold, and vicar of Yaxley, by whom he has had five children; three of them are now living in the United States, one, a daughter, is living at West Ham, and one is deceased. When he began married life he thought he was comfortably settled: prices were good; his farm of 160 acres was, to all appearance, one of average quality; his house was sub-

stantial, and moated round in the old style; and he had a partner to share his joys and his sorrows. But barberry bushes were dotted here and there in the hedges all over the farm, and to this he attributed the fact of his corn having suffered greatly from mildew. At the end of four years he had to quit, in consequence of the sale of the farm, and Thomas French, Esq., of Cranley Hall, Eye, gave him the offer of a farm at Witnesham, of 180 acres, at £40 a year less rent than what he was then paying, and, in addition, an offer of a lease for 21 years. This offer he embraced; he took stock and crops at valuation, and in 1807 took possession of the land, which he continued to cultivate for nearly forty-five years. When he came to the farm, although 160 acres of arable land, there were but two acres of white turnips grown: they were very small, and this was about the average proportion grown by the farmers in the parish. The mode of cultivating swedes was then unknown in this neighbourhood. Mr. Poppy found the white turnips almost useless on his heavy-land farm; the roads were so bad that carting them home was difficult, so that in sharp winters they sometimes rotted in the field, and in mild ones ran away so early that there was no feed left for the spring. This led him to turn his attention again to the cultivation of swedes, for which, and his experiments with the turnip fly, he afterwards became celebrated. The importance of these experiments may be judged of from the fact that one of the best agricultural authorities, Mr. Macro, has estimated the loss by the fly to amount to one year's crop out of five or six.

When, in 1827, the gold medal was presented to Mr Poppy by the Duke of Sussex, in the Haymarket Theatre, for his endeavours to prevent the ravages of the turnip fly, Sir John Sinclair introduced himself to the Suffolk farmer, and did all he could to make known the nature of Mr. Poppy's experiments.

Unfortunately for him, the promised twenty-one years' lease of the Witnesham farm was never executed. Mr. Poppy kept on farming and improving, prices were increasing almost every year, and in a few years he paid a heavy penalty for neglecting the affair of the lease. The owner of the farm and a friend visited him, and the next rent day the alternative was to Mr. Poppy either to pay an advanced rent or to quit. It was in vain that he pleaded his agreement: there was no written contract. He had himself become a family man, had expended a considerable sum in improvements, and it was not likely that another farm could then be obtained, and he had therefore to submit to the demand. His case is one among many of the folly of making improvements without security.

About this period he entered into a correspondence with Arthur Young about the "scarifier," and he sent a model of the instrument he had invented to the Board of Agriculture, at the time Sir John Sinclair was President; both Arthur Young and Sir John highly approved of the model implement, and felt sure of its getting ultimately into general use. Young, however, advised Mr. Poppy not to take out a patent, and the result is, that at the present day, scarifiers, of which his was the original type, may be seen on almost every farm in this district.

White carrots were introduced into this district by Mr. Poppy. He brought the seeds from France in 1828. Sauntering about Calais prior to embarkation, he saw some strange roots lying on the stalls of the market-place, that "looked like a hybrid between a parsnip and a carrot," and he at once bought some seed to try their growth in East Anglia. He was incessant in his labours to introduce mangold wurzel, but he for a long time met with great difficulties in persuading farmers to grow this valuable root, and he distributed seed, published pamphlets, and wrote letters to the public journals, with the hope of getting the root into general use; and there cannot be a doubt but that his exertions were of great value. Mr. Collett, of Clopton, had succeeded in growing the root, but his want of knowledge in storing them caused his crop to spoil. A labourer from that parish brought one to Mr. Poppy as a curiosity, saying, he "din't know what that was; if 'twas a carrot 'twas a stamming great un." Mr. Poppy has also been zealous in promoting the cultivation of "millett" as a useful stall-feeding plant for storing, and as a substitute for clover.

Mr. Poppy, in connection with a few friends in his neighbourhood, established the first organised Farmers' Club (the Ashbocking) for the exchange and record of the results of their practice. Of this club he was appropriately chosen chairman, and he was especially the guiding spirit of the club. His great natural abilities, extensive experience, and generous disposition eminently fitted him for the duties he undertook. By these meetings he connected himself personally and by correspondence with men of intelligence, activity, and industry—that portion at least of the agricultural body whose general knowledge and energy were far in advance of the great majority of farmers of that day, and thus, directly and indirectly, he greatly aided in propelling onward the art of agriculture in this county. After the establishment of this club, the system of Farmers' Clubs became rapidly established throughout the kingdom. Mr. Poppy is not what is generally termed an educated man, but his mind is one of no common calibre, and its strength and rugged energy have to a great extent supplied the want of educational tact. His practical suggestions have ever been deservedly esteemed by those who did not fear to travel out of the beaten tracks. He adhered to his plans with a degree of steadiness which some called obstinacy, but he was always determined that his experiments should have a fair trial, and all parties admit that his observations are acute, correct, and judicious.

In 1850, our experimentalist, being nearly eighty years of age, left the farm, and retired with his aged partner to a small cottage that overlooks every field on the farm, the cultivation of which he had so long superintended. The time at which he quitted his occupation was a bad one, stock and crops sold at very low prices, thereby greatly reducing even the limited means which this aged couple had to depend on for subsistence during the remainder of their days.

Charles Poppy is not like Tull, a gentleman of ancient family; nor like Stillingfleet, the grandson of a bishop; nor like Arthur Young, a Fellow of the Royal Society; but he is a practical agriculturist, who, in proportion to his means, has done more, by experiment and correspondence, to advance the agricultural art in this county than any other man living, and as such is worthy of all honour.

THE PROPOSED ESSEX AGRICULTURAL ASSOCIATION.—The adjourned meeting of the committee appointed to promote the establishment of an agricultural society in the county of Essex, took place on Friday, March 26, at the Shirehall, Chelmsford; Mr. C. Du Cane, M.P., in the chair, Mr. Bramston, M.P., one of the other county members, and a considerable number of gentlemen connected with the agriculture of the district, were present. The hon. chairman stated that 34 vice-presidents at £5 5s. each, 39 members at £2s. 2s. each, 151 members at £1 1s. each, 24 members at £1 each, and 269 members at 10s. 6d. each, had been enrolled, in all 517 gentlemen. The surplus arising from the local fund raised for the Chelmsford Meeting of the Royal Agricultural Society was about £315, and there was, therefore, a sum of £850 available for the inauguration and establishment of the association. With regard to the rules, the chairman further stated that he had prepared them, having previously received copies of those governing the Suffolk and the Bath and West of England Societies. The hon. gentleman's code, which he read, was adopted, with a few slight alterations. It provides for the management of the association by a committee of 24 members, chosen equally from the northern and southern divisions of the county, and that no political discussions shall be introduced into the society, which is to be devoted exclusively to agricultural objects. The meeting resolved on the appointment of a secretary at a salary of £50 per annum, and Mr. W. Tuffnell undertook to act as treasurer. It was also determined, after some discussion, that the first exhibition of the association should be held at Chelmsford, on Tuesday, June 15, and the meeting adjourned to March 26, for the reception of a schedule of prizes to be prepared in the interim, and to be then submitted for approval.

MANURES FOR GREEN CROPS.

At a numerously attended meeting of the Western District of Mid-lothian Agricultural Association, held at Mid-Calder, on Tuesday, the 1st December last, Peter M'Lagan, junior, Esq. of Pumpherston, in the chair, the following able paper on the "Manures best suited for the Turnip Crop" was read by Mr Rowat, Currievale:

The results of a few experiments with different kinds of manures are all I have to lay before you. I have no historical account of the various manures now in use; nor have I anything to say of their chemical properties. There will doubtless be a difference in the opinions of many here as to the comparative merits of different manures; but I think you will agree with me as to the necessity of applying manure of some kind if we expect to raise a prolific green crop. We all know that in carrying away from the land a crop of any kind, whether cereals or root crops, we are robbing the soil of chemical properties which must be returned to it again in one shape or other, if we would maintain the land in high condition; and perhaps one of the most difficult problems for an agriculturist to solve is the one now before us—What is the kind of manure which, at the least cost, will raise the largest green crop, and at the same time leave the land in the best condition for the succeeding rotation? A thrifty housewife, on one occasion, presented a friend who had called with skim milk cheese, bread and butter, by way of refreshment. He deliberately spread a slice of cheese with the butter, saying, "I restore unto thee what was feloniously taken away;" and if we wish to raise luxuriant crops of potatoes and turnip, we must restore to the land the chemical properties which previous crops had carried off. Manuring land is no modern practice. It is quite true some agriculturists in the present day profess to grow a succession of crops for a series of years on the same land without applying manure of any kind—and the evidence that this has been successfully done seems so complete that we cannot dispute it. Still, I think you will agree with me when I say that even in the Lothians, which has been styled "the garden of Scotland," we must apply manure, and that, too, with no niggard hand, if we expect to raise a crop that will cover seed, labour, and rent. In the wheat-growing districts of Canada, where the soil is so rich that the farmers for years did not require to give it manure, now, instead of carting their manure to the river side as the easiest mode of getting quit of it, they collect it carefully and apply it to the land. Chemical science has done much for agriculture in analyzing soils, testing the manurial qualities of various substances, and thus guiding the practical farmer to the kind of manure best adapted for the respective soil and crops to which they are applied; and yet, withal, agricultural chemistry may be said to be yet in its infancy, although it has attained to the ordinary span of human life. Yet it seems to have received no attention from practical agriculturists until Liebig published his work on the "Application of Chemistry to Agriculture." This work produced a considerable impression at the time amongst farmers, some of the more sanguine imagining that a new era had dawned upon agriculture. Greatly increased crops were to be raised by new manures, adapted to each description of grain and root crop, at one-half the former price. But alas! we all know to our cost that ever since, notwithstanding all the aid of chemistry, manures of all kinds have been gradually rising, till last season we paid a higher price for them than we ever did at any former period. Let me not be understood as speaking lightly of the aid which chemistry renders to agriculturists in judging of manures. So far from it, I believe that we may on good grounds cherish the hope that this abstruse science will yet discover for us more plentiful and consequently cheaper supplies of artificial manures. Years of patient analyses and experiments may be necessary. Let us be patient.

Let us remember what chemistry has done in supplying us with manures in time past. Thirty or forty years ago, when turnips began to be more extensively cultivated, all the farm-yard manure that could be collected was found quite inadequate. Bones were introduced, and with marked success, especially in sharp soils. Then by the aid of chemistry these bones were dissolved, and the quantity formerly reckoned necessary for an acre was found amply sufficient for four. But even with all this multiplication of the power of manure, it was found insufficient for the land under green crop. Then some sixteen or seventeen years ago guano was introduced, which met the desideratum for the time; and now, when farm-yard manure, bones, dissolved bones, guano, &c., &c., are all found unequal to manure the vast extent of land under green crops, I doubt not some substitute will be forthcoming in the time of need. To chemistry all eyes are at present directed, and I trust they will not look in vain. It is but a few months since that wonder-working science resolved the gas contained in our Torbanehill coal into a liquid, which I know some of you are pouring into your lamps, and obtaining a good light for a half-penny a night; while a wick the length of your finger will last you a twelvemonth. If that eagle-eyed science which detected the liquid gas in the dark coal-beds of Torbanehill, and made it equal if not to the light of day, at least, to a gas light more brilliant than any light these dark December days can boast, is it too much to expect that she will unlock the vast storehouses of Nature's laboratory, and bring forth the many rich fertilizers lying dormant, whether it be from the enormous beds of nitrate of soda in South America, or the deposits of fossil remains of whales, sharks, and other gigantic monsters of the deep that in some remote period of the earth's history seem to have sported their short-lived day in our seas, and had their bones deposited in the south of

England for the use of the British agriculturists of the 19th century?

To make use of a Yankee expression, I believe in chemistry, and it its power to guide us in the choice of manures. But I have still stonger faith in experiments, although these are not always safe guides. There are so many circumstances to be taken into consideration—the character of the soil, climate, period of sowing, the season, &c., &c., that implicit confidence cannot be placed in any one experiment; but if year after year we make trials of manures on different kinds of soils, and carefully ascertain the results, we shall be able to arrive at general conclusions on which we may depend as safely as any chemical theory, however beautiful.

Farm-yard manure, guano, ground bones, charcoal manure, and dissolved bones, are the manures I have made the experiments with, the results of which I now beg to lay before you. In the season of 1856 I tried six different lots of three drills each. The

First was manured with 5 cwt. Peruvian guano per Imperial acre, and yielded—21 tons 1 cwt.

Second, with 5 cwt. dissolved bones—17 tons 1 cwt.

Third, with 5 cwt. charcoal manure—12 tons 9 cwt.

Fourth, with 2½ cwt. each guano and dissolved bones—18 tons 15 cwt.

Fifth, with 2½ cwt. each guano and charcoal manure—21 tons 1 cwt.

Sixth, with 1½ cwt. each guano, charcoal, and dissolved bones—20 tons 2 qrs.

I ought to explain that the turnips were not sown till the 19th of June, quite too late to sow green top yellow, especially in such a season as 1856, and hence the crop was a very small one. I also weighed the same lengths of 3 drills of the same variety of turnips sown on the 24th of May, and manured with about 30 tons of farmyard dung, ploughed in December, and 1½ cwt. each dissolved bones and guano, applied in the drills, which yielded 27 tons per imperial acre.

This season I had a trial of seven different lots, manured as follows:—

First, manured with 6 cwts. of Peruvian guano, weighing 26 tons 19 cwts.

Second, manured with 6 cwts. Patagonian guano, cost about 10s.—26 tons 13 cwts.

Third, manured with 9 cwts. dissolved bones—22 tons 18 cwts.

Fourth, manured with 6 cwts. do. from the same manufacturer, but much drier—25 tons 11 cwts.

Fifth, manured with 6 cwts. dissolved bones, from another manufacturer—22 tons 19 cwts.

Sixth, manured with 10 cwts. do.—22 tons 10 cwts.

Seventh, manured with 3 cwts. Peruvian guano and 3 cwts. charcoal manure—25 tons 18 cwts.

These weights are all per imperial acre. I may state that Mr. Davidson and Mr. Cunningham were kind enough to assist me in measuring the land and weighing the turnip.

I tried another lot, manured with about 30 tons farmyard dung and 1 cwt. each guano, charcoal manure, and dissolved bones, which yielded 33 tons. The turnips in this last were Swedish variety: the others were all green top yellow.

I have been in the habit of making a few experiments with different kinds of manures every year. Up till last season I always found dissolved bones to yield as large a crop, or nearly so, weight for weight, as guano, and certainly the largest crop for the money value of the manure, while its effects on the land were more lasting. Whether the deficiency the last two years arose from the wetness of the season or the quality of the manure, I know not. I dissolved the bones myself previously, but I had them from a highly respectable party, and do not believe they were in any way adulterated. I was in the habit of using bone meal, or the riddlings from the bones, to assist in drying them The addition of a portion of dry bone may perhaps account for the different result. Dissolved bones, I have observed, give a great stimulus to the young turnip plant, and by sending it rapidly on, it is sooner beyond the reach of that horrid enemy of the turnip plant—the fly. In this respect it excels all other manures except guano. You will observe one remarkable result in the lot with 10 cwt. of dissolved bones; the yield is no greater than with 6 cwt. This would not have surprised me had guano been the manure, but with bones it is to me altogether inexplicable. In making a calculation of the cost of various manures used in these experiments, Patagonian produced the largest weight of turnips for the money cost, but inferior guanos are not to be depended on, with this exception. Half charcoal and half guano produce the next greatest weight of turnips for the money, reckoning the charcoal manure at 5s. 3d. per cwt. and the guano at 14s. Dissolved bones are the next cheapest.

Perhaps it may be expected I should say something of the manures best adapted for potatoes. I am not a large potato grower, seldom having more than eight or ten acres, and therefore leave that subject to another. I may state that I this year used 1 cwt. each of charcoal, guano, and dissolved bones, with farmyard dung ploughed in in autumn. A small portion of the field had 3 cwt. of guano, without charcoal or bones, and I could observe no difference in the produce. One word as to the Edinburgh Police Manure. I have found it suit well on stiff soil, but on lighter land I would decidedly prefer the one-half quantity of farmyard dung. I know this does not correspond with the experience of some of the most intelligent farmers of the district, who compare it with other manure in the proportion of three or two. One serious drawback to it is, you have even on this calculation three tons to load, cart, and spread, for two of the other, and it will take nearly double the time to fill and spread it. If liquid manure could be applied to turnips, I believe it would surpass every other manure for that crop. Some time ago, in transplanting some Swedes, I took urine from the tanks, and applied it after the turnip was transplanted, and its effects were very powerful.

The CHAIRMAN expressed the great satisfaction he had had in listening to the very able and suggestive paper of Mr. Rowat. It had brought out prominently a most important point, which was well worthy of our best consideration, viz., *the most*

profitable quantity of manure to apply to our crops. Every one present acknowledges the principles of high farming—we must be liberal to the soil if we expect it to be liberal to us. But within the last two or three years there are many instances in the best-farmed districts of Scotland in which these principles have not been judiciously carried out. Owing to the high price of farm produce, and the facilities afforded of obtaining manures, the error with the best farmers has been rather over-manuring, producing an over-luxuriance of the cereals, very much to the loss of the farmer. By all means let as much manure be applied as will give the most profitable return to the farmer; but having ascertained the quantity that will produce that effect, let care be taken that it be not exceeded. Were the cost of a ton of turnips to be counted up on some farms of particular kinds of soil, and where large doses of manure had been applied, considerable astonishment would be felt at the expense. In some cases which came under our observation this season, we found that the cost of raising a ton of Swedes was 12s. Now, turnips seldom pay more than 6s. or 7s. per ton when used for feeding, and this year there are not many feeders that will make more than half that sum. These remarks have been suggested by an experiment of Mr Rowat's, where 6 cwts. of dissolved bones per acre gave as large a crop as 10 cwts. of the same substance. It will be said that the 10 cwts. will tell upon the succeeding crop. True; but why apply the extra 4 cwts. to the turnip crop. The money paid for it would have been much better lying at interest in the bank, or applied in some other way for a year till the next crop was sown. But we maintain besides that there is considerable loss in the manurial value of the superphosphate by applying it to the soil a year before it is required. Another important fact stated by Mr. Rowat is that charcoal manure, which possesses by itself a comparatively inferior manurial value, is found to produce as great an effect when mixed with Peruvian guano as an equal weight of guano. We can account for this in no other way than by attributing the effect to the property which the charcoal has of fixing the ammonia of the guano. But though we have tried before now other substances which had the same property, we have never obtained such favourable results. The success attending Mr. Rowat's experiments certainly warrants a trial of the same substance used by him. The following are two experiments performed by me, the one in 1856, and the other in 1857. In the first experiment, the whole field was manured with good farmyard dung at the rate of 20 tons per imperial acre, and all the substances were applied at the rate of 26s. 6d. per imperial acre. As there was considerable variety in the condition of the soil in the field, I thought it better to make a series of experiments over the field instead of one equal portion of land being taken in each experiment, and the produce of adjoining ridges weighed—

First Experiment.

	Tons.	cwts.
Dissolved bones and Peruvian guano gave	6	2
Steamed bones do. ..	6	3
Second Experiment.		
Steamed bones and Peruvian guano ..	6	1
Dissolved bones alone	6	7
Third Experiment		
Dissolved bones alone	5	$17\frac{3}{4}$
Steamed bones alone	5	$19\frac{1}{4}$
Fourth Experiment		
Leone guano alone	4	$7\frac{1}{2}$
Leone and Peruvian	5	$12\frac{1}{4}$

Last summer a small quantity of guano from the West India islands was sent in for experiment by the Messrs. Cunningham. Turnip sowing was nearly over when it reached me; but still I determined to try the experiment on a portion of a clay field in not first-rate condition.

	Tons.	cwts.
4 cwt. of Peruvian guano per imp. acre, gave	4	0 of tops.
	13	11 of roots.
8 cwt. of West India guano per imp. acre, gave	2	15 of tops.
	11	10 of roots.
2 cwt. of Peruvian and 4 of W. Indian per imp. acre gave	3	7 of tops.
	15	1 of roots.

Messrs. Glendinning, Hatton Mains; Allan, Clifton; Walker, Kilpunt; Black, Newyearfield, also took part in the discussion, detailing the experience of the application of different kinds of manure. Two experiments mentioned by Mr. Rowat gave rise to considerable discussion, viz, those in which it was found that 8 cwt. of dissolved bones produced as large a crop as 12 cwt. of the same substance, and where 4 cwt. of guano, mixed with 4 cwt. of charcoal, at a cost of £3 16s. produced as large a crop as 8 cwt. of guano alone, at a cost of £5 12s. The opinion of the meeting appeared to be that every farmer should ascertain for himself, by experiment, the proper and most profitable quantity of manure to apply per acre on his farm according to the condition of each field, so as to raise the fullest crop; and that having ascertained that quantity, it would be injudicious to apply more, as a larger crop of turnips would not be raised, while there was a risk of injuring the succeeding grain crop.

The Chairman concluded by moving a vote of thanks to Mr Rowat for his excellent paper.

HOLLY (Ilex aquæfolia)—Common holly—is one of the very best shrubs or trees we possess, displaying either character, according to situation, age, and application of art; it is found (according to Loudon) in most parts of Europe, in North America, Japan, and in Cochin China. In Britain it is found congregated in natural woods and forests: but for the purposes of this article (viz., in hedges) the holly stands pre-eminent. It will not be necessary here to describe the somewhat tedious practice of raising the plants by seed; we will suppose that a hedge is intended. It is always necessary to well-trench the soil, and prepare a space sufficiently wide to receive the plants. That their roots ramify by adding to the original a portion of well-decomposed manure, or rich compost would be aswell. Then say in September or October, or in April or May, select from some respectable nurseryman plants that have been repeatedly removed (this point is of great importance to insure success), of such size as suits the taste or means

of the purchaser; but we will start with a plant one foot high, which should, when well established, receive proper pruning by cutting in, to the required breadth, such irregular or luxuriant shoots that project beyond the limit allotted to them: this concentrates all the energies of the plant to the purposes intended—the forming a good hedge. After two or three years, it may be found necessary, perhaps, to stop a few of the most naked and strongest leaders, should they start beyond an ordinary growth; otherwise there might be hollow places found, which would spoil the general effect of an even outline. It would, under every circumstance, be advisable to use a knife, and not the shears, as they rather mutilate the plants; in fact, it is a barbarous practice at all times, to apply the shears to good evergreen hedges. Beyond an occasional top-dresssing or a little mulching, the work is done, and the extra pains taken in the early growth of hollies will amply repay the planter for his trouble, and he may in after-years look with pride on his handy work.

THE GROWTH AND MANAGEMENT OF WOOL.

At a late monthly meeting of the Haddington Agricultural Club, Mr. Gaukroger, wool merchant, of Haddington, said he had been called upon so unexpectedly to preside at that meeting, and had latterly been so much engaged in buying and packing wool, that he had no time to prepare a few remarks anent the growth and management of that staple commodity. It might be assumed, however, that any one practically acquainted with that branch of commerce could not be at a loss for a few words on the subject. The first step incumbent upon those aspiring to become growers of first-class wool, is to be particular in obtaining a clean, healthy, and pure stock. Take for instance the sort of wool most in demand at the present moment—half-bred hogs—in order to obtain the extreme prices now going, there must be no infusion of blackfaced blood. Let it be as remote as you like, it will show itself in a greater or less degree, and, wherever prevalent, seriously deteriorates the value of this class of wool. They shall be crossed for years, and crossed again, till not the slightest symptoms can be discovered in the head or legs of the sheep; but to a judge the tinge of blood is at once detected in the wool; it is heavily britched, and hardly ever free from kemps—a vile, thick, dead white hair, that all staplers and manufacturers have a great repugnance to. In a pure stock this objectionable hair is sometimes found, but generally in aged sheep; old ewes, for instance, that are draughted from breeding stocks, and sold to low country farmers, who make them and that year's lambs fit for the butcher. To produce a sound-stapled wool, it is necessary that the sheep be regularly fed; what I mean is, that they be not allowed to go back in condition, for where this is permitted, it shows itself no less in the wool than the mutton; moreover, the wool can never afterwards recover its strength, and at that point where they have been pinched of meat, the wool will be tender, and break, and will not comb, but only fit for weft or carding, and is consequently not so valuable as sound combing wool. The stronger you feed, the wool will be the longer and heavier, but not the finer haired—medium feeding is best for combining quality with a fair sound staple. The *North British Agriculturist* of May 20th, in speaking of salve or laid wool, strongly approves of not clipping the sheep till the wool is again greasy with its natural secretion. I believe this to be a good plan for laid wools, but for white wools it is not; the sooner the sheep are clipped after the wool is thoroughly dry the better—buyers don't like to see greasy, "yolky" wool, and wont give a top price for it. Provided the weather is favourable for drying, 4 to 6 or 8 days is long enough, and not 14 or 20, as some people might think. Another important feature, although a very simple one, is the winding up, or what is termed in Yorkshire the "lapping." This is too often neglected; the servant, in many instances, is careless, and does not clean the fleece of all dung, dirt, tar, straw, &c. I believe this is never done with the knowledge of the master, but they cannot be too particular in cautioning their servants in this respect. There is a law passed for the protection of manufacturers and wool-staplers, making this a serious offence, and punishable by a fine upon every fleece so falsely wound, as well as the entire forfeiture of such fleeces, and the case to be disposed of in a summary way before a magistrate. It is, perhaps, not out of place my alluding to this. I don't think it has ever been acted upon in this country. I am sure no one would like to take abvantage of the servant's mistake, as the farmers would not be cognizant of it, and are a courteous, gentlemanly, and hospitable class, which of itself even would debar any one from going to such "straits." Some districts have deservedly a better character than others for the growth of the wool. East Lothian cannot and never could compete with the border—Roxburgh and Berwickshire. These districts are famed in Yorkshire and France for what is termed Northumberland wool (which includes the wool of Northumberland, Roxburgh, Berwick, East and Mid-Lothian), and always brings higher prices. This is to be attributed to the soil and climate of those districts being better adapted to the growth of wool, and being more what is termed a wool-growing country, greater attention is paid to it. In this county there is the greatest difference possible—some places grow much better wool than others; go down to the low country and near to the sea, and then to the parishes of Salton, Gifford, and Bolton, and you will find a startling superiority in favour of the latter;—the former wants that bright rich colour and full wholesome appearance of the latter, and has a dull, "reeky", unkind aspect, and is wastier. I must state, however, that in spite of soil and climate, and the keeping of "flying stocks", there are some praiseworthy exceptions in the northern division of the county. It does not follow that the richest and best corn land produces the best wool. I can understand a

farmer supposing that; but such is not the case. The best Cheviot laid is grown in Sutherland, and some beautiful half-bred wool in Caithness, whilst the best Cheviot white is grown on the Cheviot hills and district. Again, East-Lothian wool is, I believe, preferred to West-Lothian, Fife, and other places. In this age of competition, and when wool is so very high in price, it is the interest of those who wish good prices to give this matter their consideration. Wool is not "penny pies" now: prices will vary considerably for the same description, as it is the best wool that is wanted, and buyers prefer paying at all times a good rattling price for a superior article, to a shabby price for a slovenly got up one. A good lot, when bought, is half sold to the consumer, but a bad lot sticks long, and it is up-hill work to quit it, and frequently spoils one for a future transaction. I have been taken so much at unawares that nothing else occurs to me at present, but shall be glad to hear any member's opinion on the subject.

Mr. Dowell (of Dowells & Lyon) wool broker, Edinburgh, having been introduced to the meeting by the chairman, said—From the exceedingly courteous invitation of Mr Harper to appear here, I considered it would have been most unbecoming if I did not cheerfully respond to his wish by giving a few remarks in extension of our circular, the more particularly as it touches the most important product of our island; and in following this up, I might justly be accused of arrogance, if I did not at the outset declare it was not from personal practical experience that these remarks were founded on, but what is more valuable—from the experiences of many who have enthusiastically devoted their energies in the furtherance of our native manufactures. In conversing with practical men, both producers and consumers, more particularly the latter, one feels thoroughly convinced there is still a vast field open for improvement in the getting up of the wool; and let it not be considered I am running away with the harrows too fast, when I assert that in wool there is as much room for improvement as there was in days not long gone by, when guano and artificial manures were unknown in agriculture; nevertheless, it must excite a pleasing sensation in the breast of every well-wisher of his country to observe the gradual, but marked attention, which has of late years been bestowed on rural affairs. To men of all ranks of society, agriculture seems now to be the favourite study, not only of the landed proprietor and practical farmer, who are more immediately interested in its improvements, but also of the philosopher or man of science, who, instead of wasting his time and talents in useless metaphysical disquisitions, now devotes them to agricultural researches, which, redound to the benefit, not of a few individuals only, but to the community at large. When we consider the wool of this country alone warms almost every class of society, gives employment to thousands in its manufacture, and engages whole fleets in its exportation, it should excite within every one of us a lively interest in its progress; and in a national point of view, it must be gratifying to know that the tartan and the tweed are eagerly competed for in every clime; and it affords us no ordinary pleasure to notice that the managers of some of the largest charitable educational institutions of our country have at length seen the propriety of clothing their youngsters with the becoming garb of Scotch tweed. Little does a careless farmer know of the trouble occasioned to a manufacturer from ill got up wool; and if he would but for a moment reflect on the vast amount of capital involved in machinery, it should prompt him to be more careful; and when we read of, and daily hear of, hill farms increasing in rent from 12 to 45 per cent., surely it is but hopeful that every improvement should be attempted to increase the value of the crop, whatever it may be. This I humbly submit, can only be done by care in selecting the stock; and as we are particularly on wool, the careful washing is of the highest importance to the manufacturer, inasmuch as it yields more weight of yarn, enables him to put a greater quantity through the carding process, as it does not clog up the cards speedily. Its freeness not only makes it spin more sweetly, but makes a better thread; hence it is more valuable to the manufacturer in many respects, and he well knowing the qualifications of well washed wool, is ever desirous of acquiring it even at a considerable advance. Bright-haired wool is much desired and eagerly sought after by the manufacturer, being far more valuable to him than wool tinged with the yellow hue; the production of a pure white wool free from all tendency to clamminess is what woolgrowers cannot be too ambitious to attend to, and the attainment of this object depends very much on prompt attention being paid to early clipping after the sheep has been thoroughly washed and dried. Wet or unsettled weather may interfere with such an arrangement; but, generally speaking, the delay is attributable to the idea that farmers entertain, that they gain by weight when shearing is postponed. In this they are greatly mistaken, for they sacrifice the beautiful white appearance of the fleece, a quality which cannot be too highly estimated, and which the manufacturer invariably keeps in view in the advance of price. Considerable loss is often experienced in the deterioration of wool, by allowing a flock after washing to be turned into a place where sand or moss rubs are prevalent; great care ought to be exercised in avoiding such, and in procuring the best place till the clip is finished. Of late years complaints have been on the increase from the French buyers, who have been large competitors, that kemp hair is far too often found in flocks; this should be particularly studied, and every experiment adopted to devise the means of eradication. Allow me now in a few words to draw attention to the advantage of disposing of the wool by auction, and let it not be considered I am too one-sided in this opinion, but believe me it is from an honest conscientious conviction that I am advising for the best: established usage, old connections, and an indifference to change, makes the task to prove the fact all the more difficult; but can the enlightened farmer of the 19th century not see that when wool is collected into a well-lighted store, placed in competition with others of a worse or better sort, and when the direct competition of some 40 or 50 bidders come into play, each sort receives its just reward accord-

ing to the care it has been got up with? How infinitely better then is this plan, compared to what we hope some day to see entirely exploded, viz., of accepting from the old dealer his idea of the value, and the giving of the same price in localities, let them be ill or well washed. In saying this, let me not be misunderstood by a highly intelligent and gentlemanly class of dealers, who have long occupied the wool field—that I wish to take the butter off their bread, and perhaps their bread as well. I wish even to show them that sales would decidedly be to their advantage, and why. Look at the enormous expense they are put to, in travelling the country; whereas at sales they would get what they required, with a tithe of the trouble and no expense; they would thereby be better remunerated by receiving a commission for so buying. Have we less intelligence than our American and Australian neighbours, who have long seen the advantage of sales? Certainly not! Still we are only waking up to appreciate what they have long enjoyed and benefited by in purse. Sales are now springing up in all quarters; but unless one general central market be adopted, it is easy to predict the issue; and another fallacy is the frequency of the sales. To suit all, more particularly the buyers from distant parts, set periods, such as the London practice, should be adopted, and we will ever endeavour to advance with the times in lending our aid to improve every method that will tell to the benefit of the grower. In conclusion, allow me to thank you for this opportunity of expressing my opinions, and as I was an aspirant to the enviable position of an agriculturist under the able tuition of Mr. Steedman of Boghall, I am proud of the opportunity of meeting so many intelligent cultivators of the soil.

The following members also took part in the discussion—Mr. Douglas, Athelstaneford; Mr. R. Scot Skirving, Campton; Mr. Durie, Standingstane, &c. The discussion ultimately was adjourned till next meeting, so that Mr. Harper's views on the subject might be obtained.

THE MANAGEMENT OF GRASS LAND.

1. The best mode of Laying down Land to Permanent Grass, &c.

In laying down land to permanent pasture, the first point to be attended to is its thorough and efficient drainage; for without this all-important preliminary, no matter how the other operations are conducted, disappointment will finally ensue. We need not enter into any lengthened account of the manner in which draining is performed, for the details are generally well known; but this much we must say—the drains ought not to be less than four feet deep, and, as a *general* rule, not more than 21 feet apart. We are aware that there are many persons who do not consider it necessary to drain pasture land, or what is intended to become such, as closely as they would do land intended to be under regular cropping; but we consider this to be mistaken policy. Unless the land is naturally dry, it must be rendered so artificially; for if this is not done, coarse grasses will displace those finer descriptions which may be sown, and coarse grasses are always innutritious.

Taking it for granted that the land intended to be laid down in permanent grasses has previously been under a lengthened course of rather severe cropping, combined with, perhaps, careless general management, we would beg to detail the steps which we have in many instances of this kind adopted, for the purpose of preparing and finally laying down the land to grass.

After draining, and when the surface soil is shallow and the subsoil retentive, it is of the utmost consequence to deepen it by subsoiling. We have had experience of land being laid down to grass both with and without subsoiling; and in every instance where it was omitted, if the subsoil was of a retentive character, we have invariably been led to attach a greater amount of importance to this operation. We have deepened land by means of the subsoil plough, and also by manual labour; and although in the latter case the expense was considerable, still we found it remunerative. Generally speaking, however, the subsoil plough will be found sufficient to answer the purpose. Subsoiling must in no case whatever be put in the room of or used as a substitute for draining, as it has been done by some persons. This would only lead to disappointment, and very likely to undervaluing what is in reality a most important operation when properly performed, and in its proper time and place.

The eradication of weeds is indispensably necessary, and it is impossible to be too careful and minute in conducting this preliminary operation. When the land is very foul it may be necessary to resort to a bare fallow, particularly when the grass seeds are to be sown in autumn. At the same time, even very foul land may be cleaned during the preparatory operations for a root crop, and in the summer culture of the same. By this, we mean turnips or mangel wurzel, drilled or (as it is denominated in many parts of England) ridged, from twenty-seven to thirty inches apart; any closer intervals will not permit the horse-hoe and grubber to act efficiently. When a root crop is grown, the grass seeds cannot be sown until the following spring. In the case of potatoes, indeed, the crop may be removed in time to permit sowing in autumn; but unless the land is already tolerably free from weeds, potatoes do not answer well as a preparatory crop, so far as the eradication of the weeds is concerned, because the potato must be planted at so early a period in spring as to prevent a thorough cleaning of foul land. When the autumn cleaning of stubbles can be carried properly into effect, preparatory to growing a crop of potatoes, then such a crop will be found very favourable indeed to the growth of sown grasses. In whatever mode the eradication of weeds is

performed, whether by bare fallowing, or in the cultivation of root, or, as they may be more correctly designated, fallow crops, the operation must be done effectually, and not hurried or slurred over. The couch-grass rake, which is used in many parts of England, will be found a useful auxiliary in the earlier stages of the business, but it ought not to depend altogether on this, but must be followed by careful hand-picking. Joints of couch-grass, small dock roots, and various other weeds, will escape the rake, and these can only be effectually removed by the hand. Hand picking, no doubt, adds to the expense; but it is nevertheless absolutely necessary, if it is desirable to lay the land down in a proper manner.

It is of no use attempting to lay down land to permanent grass if it is in poor condition, or what is called *out of heart*. When potatoes are the preceding crop, and autumn cleaning can be carried into effect, the manuring ought to take place before the land is rough-ploughed previous to winter. This manuring ought to consist of not less than 25 to 30 tons of farm-yard dung, and it is not necessary that the manure be fully decomposed. By the spring it will become incorporated with the soil, and there is a greater probability of a sound crop of potatoes than would be the case if the application of the manure was deferred until the planting season. In the spring, and immediately previous to planting, when the manure was ploughed down in autumn, is the proper time to apply lime. The quantity necessary depends on the nature of the soil; but in the case of loams of a medium character, that is, neither a heavy clay, nor a light, moory, or sandy soil, we have been in the habit of using from 120 to 150 bushels of lime per statute acre as it comes from the kiln. If it is not convenient to apply it in spring, the operation may be deferred until the removal of the crop. In this case we would sow eight to ten bushels per statute acre of half-inch bones broadcast, previous to planting the potatoes. In all cases which have come under our observation, we have seen that bones are almost an indispensable necessary when laying down land to permanent grass. We may be permitted to mention one case in particular as an illustration. In laying down a field of rather stiff clay loam, which had been previously heavily limed, to a part of the field bone-dust was applied, whilst the remaining portion was laid down after farm-yard manure. The boned portion was in the middle of the field. Ten years afterwards the boned land could be plainly distinguished from the rest of the field, even at a considerable distance; the turf was closer and greener, and always closely eaten by whatever stock was grazed in the field, but especially by sheep.

After the potatoes are removed, say early in September, the land must be harrowed, and all weeds carefully removed. After this apply the lime, or bones, if not done in spring, and then set the two-horse grubber to work, stirring up the soil thoroughly, both across the field and lengthways. Taking for granted that the land is either naturally or artificially dry, it will be best to lay it down to grass in a level state, that is, without furrows; and the action of the grubber ought to be quite sufficient to make an excellent seed bed. The seeds are then sown and the land harrowed, but not rolled, unless in the case of very dry, sandy, or sharp land. We shall afterwards refer to the kinds and quantities of seeds to be used.

When turnips or mangel are the crops which precede grass, the liming ought to be done immediately after the removal of the previous grain crop, before the land receives the winter furrow, so that it may be thoroughly incorporated in the soil before the application of manure for the root crop. The farm-yard manure, not less than 20 tons per acre, in combination with bones, will be applied, of course, immediately before sowing the turnip seed. As turnips do not perfect their growth until it is too late to sow grass seeds, and very likely being either wholly or in part consumed by sheep (if so, so much the better), the sowing of the grass seeds must be deferred till spring. In this case, as soon as the turnips are removed or consumed, the land must be ploughed in very broad ridges or lands, say fifty or sixty feet wide (still taking for granted that the land is dry), and even wider, if convenient. In this state it will lie until spring, when, if the crop has been entirely removed, and not consumed either altogether or partly by sheep, after the land has been thoroughly operated upon by the grubber, 2 cwt. per acre of Peruvian guano may be harrowed in, the grass seeds sown, harrowed, and rolled.

If the land is bare fallowed, preparatory to being laid down to permanent grass, we would strongly urge the necessity of being most particular in conducting the various operations of ploughing, harrowing, and weed picking, because we have not unfrequently seen bare fallows which could only be called fallows by courtesy. The land certainly was not in crop; neither was it, properly speaking, in grass; but it was bearing a luxuriant crop of couch and other weeds; and instead of attempting to remove these, their growth was merely retarded for the time by an occasional ploughing. We have, indeed, known in more than one case a crop of couch-grass hay to be taken off these so-called fallows. "THOROUGH" must be the motto, whether it relates to draining, manuring, working of the land, or eradicating every vestige of the weeds by which it is infested.

The kinds and quantities of grass seeds to be sown are regulated by the nature of the soil. On soils of medium quality, the following mixture will be found advantageous:—

Perennial rye-grass, 10 lbs.; Italian rye-grass, 4 lbs.; Timothy, 1½ lbs.; Cocksfoot, 5 lbs.; Meadow Foxtail, 2½ lbs.; Rough-stalked meadow grass, 2 lbs.; Hard fescue grass, 2½ lbs.; Meadow fescue grass, 3½ lbs.; Perennial red clover, 6 lbs.; White or Dutch clover, 4 lbs.; Alsike clover, 2 lbs., per statute acre.

In dry lands intended chiefly for sheep pasture omit the timothy and the rough-stalked meadow grass, and substitute 3 lbs. of sheep's fescue and 2 lbs. of common parsley, both of which are greedily eaten by sheep. In heavy or damp soils double the quantity of timothy as given in the above mixture; and whilst allowing only one-half of the hard fescue grass, add the quantity deducted from this,

or 1¼ lbs., to the rough-stalked meadow grass. Half-a-pound to one pound per acre of sweet-scented vernal grass may be added or not, in all soils, as pleasure dictates. It is not a valuable pasture grass; but, from the sweet smell it imparts to the hay with which it is mixed, it is to a certain extent useful on this account.

In the great majority of cases grass seeds are sown in spring along with a cereal crop, which is allowed to ripen its seeds; but when permanent grass is the object, the best plan is to sow them alone; that is, any of the cereals sown along with them, for the purpose of shelter, should not be allowed to ripen. When grass seeds are sown in autumn, a bushel of rye per statute acre should be sown at same time; and when the sowing takes place in spring, a similar quantity of any of the cereals will answer the purpose. Rape is an excellent seed to sow along with grass seeds, whether they are autumn or spring sown. From 3 to 4 lbs. an acre, sown broadcast, may be used; it shelters the young plants, and affords a most valuable amount of forage for sheep when pastured on the young grasses.

When grass seeds are sown in autumn, they will in ordinary cases have advanced sufficiently by April to admit of being lightly stocked with sheep. We are not partial to the system adopted by some, in such cases, of stocking so heavily as to eat down the young grasses to the root; for we consider that by doing so many of them are entirely destroyed. It is, no doubt, a great temptation to a man who is, perhaps, short enough otherwise of grass for his ewes and lambs, when he has a field of young grasses forward; but it is better to remove the sheep for a week or ten days at a time, after being grazed, so as to allow the young grass to shoot out afresh. In like manner, spring-sown grasses must be stocked as soon as they are sufficiently advanced to afford a full bite. Cattle must not be allowed to graze on the newly sown lands. In many districts the land is full of small stones, and all which would interfere with the scythe ought to be removed at any early period when most convenient. Some do this as soon as the grass seeds are sown; others defer it until after they have perhaps been eaten down for the first time. In either case, broad-wheeled carts ought to be used to carry away the stones, so as to prevent the formation of ruts, as will be the case when narrow wheels are employed. The frequent use of the roller is highly advantageous in smoothing and consolidating the surface.

Although the production of hay should be an object which it was desirable to attain, the grass ought not to be mown the first year, but entirely consumed by sheep. The second year's grass may be mown, but as soon as the hay is removed, let a wet day be selected to top-dress the field with 1 cwt. of Peruvian guano and 1 cwt. nitrate of soda per statute acre, after which, when the grasses are sufficiently grown, stock again with sheep. The aftermath ought on no account to be mown, neither should a hay crop be taken two years in succession. In the after-management of the land, should a crop of hay be taken, top-dressing immediately afterwards either with guano and nitrate of soda, or with farm-yard manure in winter, must not be omitted. A large extent of naturally excellent grass land has been ruined by a two frequent repetition of a hay crop, accompanied by a neglect of top-dressing.

2. The Renovation of Inferior and Worn-out Pastures.

In attempting the improvement of inferior pastures, drainage must form the preliminary operation in this as in the previous case. We know many instances where thorough draining alone has acted like magic in effecting a vast improvement of inferior pasture lands, where the grass has been changed through the influence of the drainage from being of the coarsest kind, and greatly disliked by stock, to sweet, fattening pastures, from which it was almost impossible to keep out either cattle or sheep if an open gate or a hole in a hedge could be found by them. In a case to which we would particularly allude, the soil was a very tenacious clay, and had been tile-drained at one time about two feet deep, the drains running across the slope. The grass, however, was never good; but when this land was drained four feet deep, the drains running up and down the slope, and only seven yards apart, in the first year afterwards a great change for the better was manifest, and each succeeding season added to the value of the pastures. To expect to improve inferior pastures which require draining without that operation being carried into effect, is simply to expect an impossibility; and we may be permitted to remark that there are more pastures requiring drainage, and the want of which is the primary cause of their inferiority, than many appear to be aware of. One thing we may be certain of—that as long as there is a single case of rot in sheep, we may rest assured that the thorough-drain has not been called upon to lend its aid in eradicating the evil.

If the land has become fogged, or covered with mosses, the harrow may be used with good effect; and afterwards let the opportunity of a damp morning be taken advantage of, to sow grass seeds over the parts which have been most scarified by the implement.

The application of bone-dust, at the rate of say twenty bushels per statute acre, is, we need scarcely say, a most efficient mode of improving inferior pastures. Instead, however, of putting them on the land in their natural state, another method may be adopted, and which we believe to be the better plan. When grass land is drained—pipes being used as under-ground conduit—let the filling of the drains be finished neatly, without laying the top sod on the surface. Collect these sods, and after chopping them in pieces, form a heap, upon each layer of which spread a quantity of bones, and also coarse salt. There will be thus—first a layer of earth, next a covering of bones and salt, then earth, again bones and salt, and so on, until the heap is say four feet high. The uppermost layer must be of earth. The bones to be at the rate of 20 bush. an acre, and the salt 5 cwt. The former will decompose rapidly, and become absorbed in this heap of earth. It may be applied to the land a month

after being mixed, observing to turn the heap carefully over before drawing the compost out on the field. If it is in the power of the farmer to saturate the heaps with the liquid drainings from his farmyard, the value of the compost will be greatly increased.

A compost of earth, lime, and salt is an excellent top-dressing for pastures, and very effectual in improving the quality of the grasses. Let the heap be made in layers as above described, but in this case, after being made up, it must remain untouched for at least six months. Then let two men commence at one end of the heap, and turn it over, carefully intermixing every portion of it, and adding a shovel-full of lime where it may appear to have been passed over lightly at the first mixing. The heap will be permitted to remain for two or three months longer, then turned again, beginning at the opposite end from that which was begun upon the first time. A compost of this kind is better to lie twelve months before being applied to the land, so that the particles may be allowed to be thoroughly intermixed, and also to permit certain chemical changes taking place which the lime and salt will effect in connection with the organic matter contained in the earth, and by which the fertilizing effects of the compost will be increased.

Calcareous manures alone, when used as a top-dressing, will effect great improvements in the character of pastures. We have often applied marl to poor heathy pastures, and the result was that the heaths and coarse bents became eradicated, their place being supplied by natural white clover and other sweet grasses. This practice of using marl alone in the improvement of poor grass lands is common in some districts with which we are acquainted; and *shell sand* got on the sea shore is also employed for the same purpose, and with precisely a similar effect. Even common sand will be found to improve the pasturage on poor clays. We had on one occasion a very striking proof of this being the case. A field of poor, ungrateful clay was laid down to permanent grass, and although it had been previously treated liberally, the grass still was always very thin, and of extremely indifferent quality. A considerable quantity of fine sand was drawn and spread over the worst parts of the field, and from that time the sward began to improve, becoming thicker every year, the bare spaces being filled up by sweet herbage, which did not exist previously.

All pastures which are eaten down by cattle ought to be frequently gone over, and all the droppings carefully scattered. This prevents the grasses from growing in tufts, as in the case where this precaution is not adopted, besides helping to improve the pasture generally.

An unremitting warfare must be waged against weeds, and the most effectual mode of removal is by digging them out. Cutting them down *regularly* at an early stage of their growth will weaken them so much that in course of time they will die out; but this is apt to be neglected until they perfect their seeds, when it is too late, and we therefore prefer recommending digging out instead of merely cutting down.—Irish Farmer's Gazette.

THE BEAUTIFUL IN AGRICULTURE.

Both the art and the science of agriculture are sufficiently advanced in this country to enable its citizens to study and practise the Beautiful in planting, and in all farming operations, with entire success. Beauty in rural objects and scenery is not confined to embellishments, but is attainable in all that relates to plants and their culture, to domesticated animals, forests, parks, fields, orchards, and gardens. Nature kindly favours, and often suggests agreeable features to such as have an eye to see and heart to feel the charms of beauty. She aids in a thousand ways to quicken into life and activity the dormant taste for the Beautiful placed in every bosom by a beneficent Creator. To develop and cultivate this latent and prolific source of enjoyment in mankind, is one of the highest duties of educated persons. It should prompt all to investigate the elements of beauty in natural objects and in rural arts, whether they relate to the vegetable, animal, or mineral kingdom. With each of these grand departments of Nature the cultivator has much to do; and he should learn her processes and laws, from which he will at length fully understand that Beauty and Utility are integral parts of any wise system of farm economy.

If beauty in a country residence, in farm buildings of whatever kind, or in tillage, were incompatible with anything that is useful in agriculture or important in household affairs, the fact would excuse the general neglect of this principle in nature. But so far from being hostile to the creation of wealth, or to its accumulation in the hands of the owners of the soil, Beauty is one of the most reliable elements of money value in every species of property. In proof of this, we cite the facts that a beautiful horse often sells at from £70 to £120, where an ugly one of the same weight and muscular power will bring only a fifth of the sums named. A beautiful plantation has equal advantages over one quite destitute of pleasing and attractive features. As society advances, and the popular appreciation of lovely and captivating expressions becomes more acute and refined, it is obvious that Beauty must appreciate in cash value. Indeed, not one in a thousand knows how to turn to the most profitable account the intrinsic power and the solid merit of the Beautiful in agriculture. It is not, as many suppose, a mere ideal matter, having no foundation in things substantial and enduring; but it is a material part of that perfect economy which owes its existence to the Supreme Architect of the universe. Hence, as planters and husbandmen, it is a part of our highest wisdom to cultivate that faculty within us,

which happily discriminates in the varied fruits of the earth, in its ever differing inherent fertility, and its wide range of really valuable plants and animals. We should study to multiply delightful objects and scenes around our homes, and improve such as Nature has scattered with a liberal hand over all our acres, whether few or many.

Let us consider what it is that renders land beautiful for tillage.

Consider the first and most obvious wants of all cultivated ground, and it will be seen that *fruitfulness* is the function most needed. It is, however, no more necessary to successful agriculture, than expressive of natural beauty. A rich soil clothes itself with noble forests; and if these be removed, as on extensive prairies, with the most luxuriant and nutritious grasses. Fruitfulness of the earth being an essential element of rurul beauty, to impair the fertility of land is not merely to diminish its money value for the growth of crops, but to transform a landscape that once inspired universal hope, confidence, pleasure, and industry, into a barren waste, which, when fairly tilled, promises little reward to honest toil, and actually yields less than it promises.

Under such circumstances, it is fortunate that Science teaches us how we can best change a sterile field, or an impoverished estate, into one distinguished alike for its elegance and productiveness. Science also tells us that it is easier and better to *preserve* the natural resources of land, than to restore them when removed in crops, or washed away by many heavy rains falling on shallow-ploughed fields. To avoid loss in this particular, it is important to know the precise things in the soil that form agricultural plants, and how these things are both lessened and augmented in all farming operations. With this professional knowledge, the cultivator may profitably increase the beauty and value of every rood of land on his plantation.

Having a critical knowledge of the constituents of soils and their products, how is one to make a truly beautiful landed estate?

This depends mainly on the circumstances with which he is surrounded. He should examine these with the utmost care, with a view to learn what is practicable, not in itself, but to a man of his means, acquirements, family ties and duties, and powers of execution. Farm buildings and fences of some kinds are indispensable; and in their construction and arrangement his taste and skill will inevitably be revealed to his neighbours and the public. A cultivated taste may be seen as well in the erection of a log cottage as in that of the most costly mansion. Nature displays the Beautiful not only in the lowly and humble violet, but in plants and animals too small to be seen by the naked eye. Wisdom in the designer may be shown as effectively in the arrangement and structure of little things as in large ones. Dwelling-house architecture, whether in cities, villages, or strictly country residences, is susceptible of great improvement, judging from the habitations of the million. These rarely possess either convenience or beauty, or any other merit to recommend them. Even in cheapness, they fail as much as in other respects. The amount of money thrown away by the rich, and those who would fain pass as such, on expensive buildings, shows how little our taste in such matters has been improved over that of savages. Fortunes are often squandered in a few years on misshapen palaces and villas. Some, less extravagant in outlay, are more *outré* in architectural folly, adding to the residence of a private family, by way of ornament, what would appear to be massive columns, but which are generally made of wood, in the ridiculous ambition of appearing to live in something like a Grecian temple. In costly public edifices, columns are appropriate, to aid in supporting the great weight of a marble, granite, or other structure; but nothing is more like an eagle's feather stuck into the matted hair of a savage, than the frail plank pillars or columns, painted white, so ostentatiously stuck out in front or at the sides of a dwelling-house. A worse taste can hardly be imagined. Simplicity, neatness, and quietness ever indicate contentment, gratitude to God, and the promise of a long happy life. Whereas, the straining for effect always suggests unfavourable thoughts, and not unfrequently provokes remarks expressive of contempt rather than of admiration.

Whatever contributes to the comfort of a family at a rural home, adds to its beauty, if properly placed and constructed. Thus, a well-arranged kitchen, with a wood-house, cement cistern for holding rain water, and many other conveniences, are not only matters of interest, but really increase the attractiveness of a family residence. It is the judicious planning, combination, and management of all the affairs, both in doors and out, on a farm, that make the farmer's life happier than that of most other men engaged in different pursuits. He has the constant assistance of those wonderful powers known as vegetable and animal vitality, to multiply his agricultural wealth and beautify his plantation. Groves of forest trees, orchards of fruit-trees, as well as all the benefits of the garden, are at his command. Parks, lawns, and pleasure-grounds he and his children may indulge in, if their tastes appreciate and enjoy such improvements; and it is better to cultivate a taste in this direction, than that which seeks amusement by visiting distant watering-places and the gaieties of cities. To the owner and cultivator of the soil, *home* should be the most agreeable place on earth. There his best thoughts and efforts, his money and his ambition, should find full employment. Absenteeism is fatal to the Beautiful in agriculture. A farmer should not only stay, as a general rule, on his farm, but *live* there, in the best sense of the term. This idea does not conflict with a reasonable amount of travel, either for recreation, or to obtain additional knowledge. Good books are now so cheap and abundant, that a library composed in a large degree of works on agricultural and horticultural subjects, is found to yield both amusement and instruction on better terms and of a better quality than the planter can obtain from any other source. It is quite as easy to acquire a taste for agricultural reading, as for tobacco, tea, or coffee. Man is a creature of habit; and the best way to avoid bad habits in our children, is to fix

early in their constitutions pure tastes, the gratification of which will ennoble, not degrade them. To cultivate the Beautiful in rural life has an elevating influence on society, and thereby prevents vice and crime, poverty and suffering.

Nature being the source of Beauty, we are to study her admirable processes as they are made known in the Natural Sciences. Chemistry, Botany, Geology, Vegetable and Animal Physiology reveal to the human understanding a thousand charms in the perfect harmony that pervades every form and condition of matter, and thus perpetuates all the beauties and blessings which call into activity both the gratitude and the reasons of man, The powers within him, and the elements that surround him, act in concert to force his growth in morality and knowledge, that he may become in each succeeding generation at once a happier and a wiser being. In connection with our moral and intellectual development, so natural and so desirable, a higher degree of social and physical comfort is clearly both attainable and susceptible of full enjoyment. It is not every person, in whatever condition he may chance to be, in reference to culture, who is capable of appreciating either the Beautiful in Agriculture or in Nature. Hence, in all nations just emerging from barbarism, husbandry, tillage, architecture, and all other arts, are prosecuted in the rudest manner. Some rise more rapidly than others in every attainment; but time is necessary to the growth of every art and the perfection of every science.

It is humiliating to our pride as a free, self-governing people, to know that in ancient Greece the Beautiful in agriculture and architecture was far in advance of our highest achievements. A thousand years before the birth of our Saviour, Homer describes, in the fifth book of the Odyssey, a landscape in which four fountains of white (foaming) water, each springing in succession, in perfect orderliness, sends the life of vegetation through a meadow in different directions. At that early period, agriculture was sufficientiy advanced to have irrigation and meadows properly appreciated by the most civilized nations. We wish we could say as much for the agriculture of our own sunny South. But all must admit, that, with us, neither irrigation nor meadows are regarded as worthy of public attention. It is true, we know the value of hay, and consume many a bale from the North, for which we pay at least twice what it it is intrinsically worth.

Who needs to be told that luxuriant meadows, pastures, and fine stock, add largely to the beauty, interest, and value of a plantation? Irrigated meadows and pastures are an inexhaustible source of manure for enriching the tilled lands on a farm. Where Nature periodically irrigates river bottoms, the plough never exhausts the soil. Running water being Nature's grand restorer in tillage and cropping, why not use it to rejuvenate our old fields, and thus render them at once both attractive and profitable? None of them are so elevated that water does not fall from above them, and run off their surfaces. Properly considered, all th moving water on continents is rain water. It creates, as well as transports from one place to another, the fertility of properly-irrigated lands. The fertilizing influence of water, when judiciously applied to the earth, is well known. It is, therefore, in skilful hands, an invaluable element of fruitfulness and beauty. More knowledge and higher art will one day use water in this country as successfully in agriculture as was ever done in Greece, Italy, or Egypt.

Next to irrigation, we regard the planting of the seeds of all the more valuable forest trees and fruit trees that will grow and prosper in our climate as the most commendable practice, with a view to promote the Beautiful in agriculture. Land is now cheap; and there is a certainty, as population increases, that the demand for lumber and timber, for fruits of all kinds, and for fuel, will increase in an equal, if not a greater ratio. By skilful planting, one may unite beauty and profit in an eminent degree. Black walnut planks are now worth, in all northern cities, from four to seven dollars per 100 feet. With due care, the tree grows rapidly, and its fruit possesses considerable value. A forest of this and other well-known trees would add an interesting feature to any plantation, while the expense of it would be a mere trifle. There is genuine poetry in trees—in their beautiful foliage, their charming blossoms, their delicious fruits, their cool and soothing shade, their stately trunks, waving tops and graceful outlines; and all speak to the eye and soul of man in a language not to be misunderstood. It was in the light and shade of groves that man first erected his most elaborate temples, and there his ascending devotions sought communion with the Creator of all. No wonder that groves were often held as sacred to God, and still oftener made seats of learning—the chosen schools where sages taught, and thousands studied the profound mysteries of the universe. If the history of our race shows anything good in man, it may be stated, to his credit, that noble trees, of whatever kind, inspire something akin to piety in his heart and in his thoughts. Call this, if you please, an oriental feeling: it has been too general and too long continued, not to have an abiding place in the human soul.

It is the crowning beauty of a farm or plantation, to express, in its every feature, both tranquillity and happiness. Disquietude and pain will sometimes come to the best of men; but their continuance should be as short as possible. It is monstrous to suppose that our nerves are made sensitive that they may feel more suffering than pleasure during our existence. Pain and distortion are exceptions; enjoyment and beauty are the true, the natural *status* of all sentient beings. When healthy, and properly fed, the young of all animals are beautiful and happy. Such is the law of Nature; and hence good husbandmen improve their flocks and herds in symmetry of form, in elegance and elasticity of movement, by simply having them always in the enjoyment of suitable food and shelter. These expel deformity in a few generations, and develop Nature's highest beauties. The same principle applies to the feeding and care of agricultural plants. Starve and wither them by ill-usage, and your seed will soon degenerate, your crops fail, and your success in planting be no better than your practice.

Nature's beauties, whether in plants or animals, are fed liberally; and in this regard she teaches the cultivator to feed generously his soil, his crops, and his stock. By so doing, his land and all its products will be the best of their kind, assuming good common sense in the primary selection. Fences, buildings, and farm implements should be made of the most durable materials, that everything may indicate the settled purpose of the owner to have such an estate as will support a family in affluence in all time to come. Permanency of occupation and durability of improvements are material elements of agricultural beauty. A witty Englishman has remarked, that in travelling through the United States, most of the houses appear to have been put up Saturday evening, with the expectation that they were to be taken down Monday morning! Much of our farm improvements are of the same frail and ephemeral character. We must learn to do our work better, or we shall greatly damage the State in which we live, by increasing its old fields, and perhaps provoke the curses of our own posterity. To injure the soil over millions of acres is a wrong of fearful magnitude. Would to God that we could see some evidence that the evil will be any less during the life-time of the writer. The error is too old and deep-rooted for that. For a little immediate gain in cotton or grain, our natural and valuable forests, the soil, and the best interests of society are all sacrificed; as if to desolate the earth were man's highest profit and greatest good! Who will try to remedy this obvious social disease, and foster the study of the Beautiful in Agriculture.—American "Southern Cultivator."

PLEURO-PNEUMONIA.

At a late meeting of the Probus Farmers' Club, Mr. William Trethewy in the chair—Mr. Karkeek delivered an able and instructive lecture on "Pleuro-pneumonia."

Mr. KARKEEK commenced by saying that he felt it was unnecessary for him to make any apology for introducing the subject; for although Cornwall had been, comparatively speaking, free from this dreadful murrain—in consequence of Cornish farmers having been for the most part exporters, rather than importers of live stock, and therefore having but little intercourse with infected districts—yet within the last few months the disease had appeared in this county. He believed he was correct in stating that the few cases which had occurred in Cornwall might clearly be traced to the introduction of cattle from some eastern counties, and might rightly be regarded as isolated instances. It sometimes, however, happened with respect to epizootic diseases, that there was a fulfilment of the old proverb—"it never rains but it pours;" and he could safely verify the fact that some of the disease which had affected our horses, cattle, and sheep of late years, had come, not, as it were, in single drops, but in a complete downpour. This had been particularly the case with the "influenza" in horses, and the "vesicular epizootie," a disease characterised by the formation of vesicles on the tongue, lips, and feet of cattle and sheep. The "variola ovina," or sheep-pox, was another instance. This disease was imported from foreign countries, and wherever it had appeared it had killed its thousands. Fortunately for Cornish farmers, it did not cross the Tamer. He mentioned these cases in order to warn his hearers that, although the murrain known as "pleuro-pneumonia" had not yet visited Cornwall to any great extent, yet it behoved them to be watchful and fearful, for epizootic diseases of all kinds appeared to be borne on the wings of the wind, and it was inpossible to say whence they came or whither they were carried. In those countries in which the disease had prevailed, it had been found extremely difficult to track its course. So uncertain was its appearance, that it frequently broke out without the introduction of strange beasts, or any other assignable cause; and in a few weeks it spread like wild-fire. In such cases the atmosphere was regarded as the medium through which the disease was conveyed. That this disease existed on the continent for several years before its appearance in England, was an undoubted fact; and hence arose the question—How did it reach England? Was it by direct importation of foreign cattle? or was the disease wafted on the air, as had been the case with Asiatic cholera and other similar pests? In every instance of the disease that had come under his own observation, it was clearly traceable to direct importation of cattle from other districts. But, as he had before observed, the malady had been known frequently to break out without any such direct and immediate cause. Thus much of the disease, however, was known—that it had prevailed in England, to a greater or less extent, since 1842; that it had been raging in Ireland for some twelve months before that period; that it was brought to the English side of the channel by some half-starved Irish cattle, and in a very short time it found its way into Cheshire, Shropshire, Staffordshire, and Middlesex; that its ravages had been the most extensive on marshy districts and in ill-ventilated crowded cow-houses; and (a fact well deserving notice) that the wide spread of pleuro-pneumonia was occasioned by persons sending their beasts to markets and fairs on its very first outbreak on their premises. From the peculiar incubating character of the disease, it was obvious that it might be conveyed long distances during its formative stage. This was consistent with the supposition entertained by some medical men, that malignant epidemics are the result of parasites—vegetable or animal—each, after its own kind, disturbing in sundry ways, the functions and the structure of the bodies on which they subsist; and that the germs of disease thus caused may exist for some considerable time before the appearance of its outward symptoms. In pleuro-pneumonia it

is supposed that ten or even fourteen days may thus elapse after the period of infection before the disease becomes outwardly apparent. This parasite theory, Mr. Karkeek observed, received some support from the little that was known concerning the properties of parasites: and this was a subject of much practical importance to the farmer. In the first place, such sources of infection were destroyed by a temperature above 120 degrees Fahrenheit, and also by strong chemical agents, especially chlorine. Their activity was also impaired by cold and by free ventilation. On the other hand, warmth, closeness, and filth, increased the virulence of the contagion, and became as it were a nursery of pestilence. Nothing tended to promote the spread of an infectious disease, such as pleuro-pneumonia, more than the crowding together of cattle which were affected by it. Each of those animals was a separate source of contagion, and the air would be contaminated in proportion to their combined action. It might be asked, how the empoisoned air produced its morbid results? He answered—not by direct irritation of the lining membranes of the air passage, but by specific action on the blood; which fluid, thus acted on, did, by its changed condition, virtually, though not immediately, affect the pulmonary tissue. In proof of the assertion that vitiated atmosphere does not act as a direct irritant to the pulmonary tissue, or mucous membrane of the air passages, Mr. Karkeek remarked that the usual symptoms of catarrh or bronchitis are never the precursors of pleuro-pneumonia. And again—if vitiated air acted as a direct irritant of the pulmonary tissue, both lungs would be equally affected; whereas it was well known that the disease was very partial—affecting more frequently the right lung than the left. Hence, pleuro-pneumonia could not be considered as an inflammatory disease, in the strict meaning of the term. It might be asked why this aërial poison affected only the lungs? This was a question not only easily answered. This much was known, that the choleraic poison acted on the intestinal canal, the poison of small-pox re-acts on the skin; that of glanders on the mucous membranes of the nasal cavities, while the poison of pleuro-pneumonia acts on the lungs. He had already stated that pleuro-pneumonia could not be considered an inflammatory disease, in its origin; and of this, the absence of all ordinary symptoms of pneumonia was proof; but there could be no question that inflammation was one of the results of the disease. It was more frequently regarded as a dropsical, than as an inflammatory disease. Evidently the empoisoned air produced considerable debility of the vascular part of the lungs, and serum was effused almost immediately; hence the dropsical character of the disease. As it progressed, inflammatory action was set up, accompanied by congestion, with effusion of lymph and serum into the interlobular structure of the lungs and the cavity of the chest. He was of opinion that this serous effusion took place before the animal's health was observed to fail. Proprietors of cattle should therefore be early and late with their stock, when pleuro-pneumonia prevails in a district, narrowly watching the slightest indication of ill health. The usual symptoms he described were;—A slight, but husky cough would be occasionally observable about this time, and perhaps the breathing would be with increased effect, as if the animal had undergone some unusual exertion. In milch cows, besides the above symptoms, there would be a diminished supply of milk. As the disease advanced, the cough became more troublesome and husky; the respiration became hurried, the pulse increased and oppressed, the appetite diminished, rumination suspended, bowels constipated, and the surface of the body chilly. The disease still advancing, the respiration became more difficult, laboured, and painful; the poor animal was frequently found lying, the head protruded, the mouth covered with frothy saliva, the muzzle cold, rigors frequent, and the pulse rapid and indistinct. Approaching death was shown by moaning, grinding the teeth, loathing of food, coldness of the extremities, wavering pulse, distressed breathing, liquid stools, and distention of the bowels. From this description of this terrible disease, it must be evident that blood-letting could be useful only at its commencement; bleeding should be early, or not at all; at the very beginning of the disease it might do good, but at its later stages bleeding would but hasten its fatal termination, since in proportion to the extent of dropsical effusion would be the debility of the patient. It was supposed by Mr. Simonds, of the Royal Veterinary College, that early bleeding might withdraw a portion of the vitiated fluid that had laid the foundation of the disease. Another remedy frequently adopted was the use of purgative medicines. In most diseases affecting the ox tribes, it was found that gentle aperients were beneficial; but in pleuro-pneumonia, strong purging should be avoided. Diuretic medicines might be useful, as in dropsical diseases, for stimulating the kidneys to increased action. He had little faith in sedative medicines or diaphoretics in this disease; but diffusible stimulants and tonics were valuable remedies, at the commencement of the disease, after the operation by purgatives. In the latter stages of the disease, vegetable and mineral tonics would be found useful. A veterinary friend had used creosote with considerable success; he (Mr. Karkeek) could be disposed to try its effect when opportunity offered. After speaking of the necessity of occasional relaxation of the bowels, in connexion with the use of the above medicines, Mr. Karkeek further recommended the application of a seton to the "*dew-lap*," and of blisters to both sides of the chest. In conclusion Mr. Karkeek remarked that there should be no specific for this disease; and that he who should undertake its treatment without a knowledge of its nature, and of the structure and functions of the organ it affects, would act like an ordinary artisan who should set about the repairing of a watch, the wheels and levers of which he had never investigated. Inattention to contagious diseases had occasioned much mischief and loss of property; and there could be no doubt that, if proper precautions were taken on the first appearance of pleuro-pneumonia in any neighbourhood, its ravages might be considerably mitigated. On the outbreak of a disease of this kind on a farm,

the first thing to be attended to is the removal of the infected beasts to some suitable place far from the other cattle, where they can be watched and receive medical aid, without endangering the healthy animals; and these too should be carefully inspected daily. Finally, he would impress upon his hearers the strong necessity for judicious feeding, proper drainage, ventilation, and cleanliness generally, as rendering cattle impregnable, to some extent, against-infectious diseases. A striking proof of this was exhibited in the well-known fact that the high-bred cattle generally of England had been comparatively exempt from pleuro-pneumonia; the obvious reason being that more attention was paid to their health and general comfort than was paid to ordinary cattle.

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE CULTIVATION, STORING, AND USES OF MANGEL WURZEL.

The usual monthly meeting of the Club was held on Monday evening, March 1st, at the Club-house, Blackfriars.

In the unavoidable absence of Mr. Owen, the Chairman for the year, Mr. Henry Trethewy, of Silsoe, Beds., took the chair, supported by Messrs. Owen Wallis, William Bennett, T. E. Pawlett, L. A. Coussmaker, J. Tyler, James Thomas, W. Gray, S. Skelton, W. Shaw (Coton), J. Wood (Sussex), J. Wood (Croydon), J. Cressingham, H. Gibbons, G. S. Harrison, Ibbott Mason, J. A. Clarke, J. Ekin, Hammond, W. Eve, R. Peacey, W. Banwell, C. J. Brickwell, W. P. Lamb, E Purser, G. Wilsher, J. A. Williams, J. Miles (Wexcombe), T. Stagg, T. Chandler, J. B. Spearing, S. W. Squier, J. Odams, &c., &c.

The subject fixed for discussion, at the instance of Mr. R. BAKER, of Writtle, was stated in the following terms:—"The cultivation and storing of mangel wurzel, and the best modes of using it for feeding and other purposes." Mr. Baker brought with him from his farm a number of specimens of the root in question, that he referred to, several times in the course of his introduction, and which were generally admired for their development and freedom from prevalent defects.

The CHAIRMAN, in opening the proceedings, remarked on the importance of the cultivation of mangel wurzel, and observed that the feeling of the committee on the subject was shown by the fact that roots were set down for discussion, in one form or other, no less than three times during the present year.

Mr. BAKER said: Of all our root crops the most important is mangold wurtzel, of which we may say, as its name imports, that it is "the root of scarcity;" in other words, it is the root to be depended upon during a scarcity of other food, and, with the exception of the Swedish turnip, there is undoubtedly no other description of root either so serviceable or productive, whilst in many particulars it is far superior even to that. In combination with the swede, in feeding, it fills a place which that root has failed to supply, and it is especially adapted for feeding late in the spring, after the turnip has lost most of its nutritious qualities. It is also more certain to plant well. It is less liable to injury from excess of drought or moisture. It can be stored during the autumn with less injury to the land than follows the removal of a turnip crop during the winter months, and under the improved system of management can be applied to the feeding of neat stock and sheep throughout the whole of the year. Independent of these numerous advantages, it is also more productive than any other description of root; it can be grown with advantage upon almost every description of soil, especially strong loam or clay—totally unfit for turnip cultivation—and during the winter, when severe frost prevails and turnips become almost useless, it can be used with equal advantage as at other seasons, provided due care is taken in storing to keep it from the action of the frost, from which, like the potato, it is liable to become injured, and even rendered useless, should it happen to become entirely frozen Within the last five years both the Swedish and common turnips have deteriorated to such an extent as to have become (upon soils on which they had been repeatedly grown for several years in the ordinary rotation) almost useless. In addition to the disease called "fingers and toes," which has of late been very prevalent, another disease has appeared, in a certain degree similar in its effects to that which has proved so destructive to the potato, and which in the present season especially has rendered the turnip-crop almost worthless throughout the kingdom. At the same time, however, mangold-wurtzel has produced a crop unprecedented for weight and quality; nor does it deteriorate like the turnip, by being grown upon the same soil for many years successively, as instances can be adduced where it has been grown on the same land for many years together, without in any way becoming depreciated in quality or quantity, but has rather improved year by year the longer it has been grown (Hear, hear). The application of guano and superphosphate of lime to the turnip-crop is equally effective for mangold-wurtzel, and affords the cultivators of strong clay soils an opportunity of growing it at a reduction of expense previously unknown, and with an advantage that can scarcely be sufficiently estimated. It is, however, best adapted for, and is most generally grown upon, tender and strong loamy soils, as the difficulty which sometimes arises in wet seasons of carting the roots from the field renders the removing them from strong tenacious clays a hazardous process at all times, and in some seasons impossible to be effected unless by employing men to carry them to the sides or the fields in baskets, which cannot be accomplished at a less expense than from 20s. to 25s. per acre. This valuable root has been grown successfully in Essex within my knowledge upwards of 40 years. The long red variety was at first the only one cultivated; the globe varieties of both red and orange were subsequently introduced, and at a later period the long orange. Little improvement has taken place by cultivation in the long red variety; indeed, I consider that it was as good, if not better, 30 years ago, than at the present period. Great care, however, was then taken to select it for seed whilst growing, and ultimately to change it from a heavy to a light soil, as it has always a tendency to become too fine and slender in the form of the root if grown successively upon light soils, too thick and short upon heavy soils, and in a few years, unless properly changed, it would degenerate alike in the form, character, and colour of the roots, upon which the quality and productiveness of the crop greatly depend. The crown of the root should not rise in any material degree from the base. The foot-stalks of the leaves should partake of the

colour of the root, a light red, and not be too many in number, but branching gracefully from the base. There should also be a similarity in all the roots, which in their form ought to be nearly alike, ending below in a single tapering tap-root of small dimensions, without any fangs branching from them, to prevent their being easily drawn from the soil, without the assistance of an implement to effect it, but yielding at once easily on the slightest application of force being made. This desideratum cannot be obtained when the seed has been grown from small plants raised in the previous autumn, but only by carefully *selecting* the *roots* one by one from the field whilst growing, and rejecting those which when pulled have not the requisite qualifications of colour and shape, especially at the crown and root. The difference in the cost of producing seed from roots thus selected, and from plants as before stated, varies from 300 to 400 per cent. Seed from plants is apt to run off with a seed-stem in the first year, whilst that produced from full-grown roots is less likely to do so. Planting very early likewise produces the same tendency, and it is in a general way not advisable to plant before the middle of April nor after the middle of May. The system of cultivation as carried out by myself is to plough up the land intended for this crop immediately after the previous grain-crop has been removed. The land best adapted for the purpose is that upon which wheat has succeeded clover. The land in the first instance ought not to be ploughed beyond the ordinary depth, until, by repeatedly scarifying and harrowing, the couch and root weeds become extirpated. About the middle of October the soil should be stirred an extra depth, which can be easily effected by the ordinary plough, followed immediately by a skeleton-plough or grubber, furrow by furrow, until the whole is stirred from ten to twelve inches in depth. Ridges should then be formed two feet eight inches wide, in the contrary direction of the field, and a grubber be passed up each of the furrows the full depth of the ploughing. If opportunity will allow, the ridges may be re-ploughed, and the operation of grubbing the furrows repeated as before. This process may, however, be thought too expensive, but the improvement of the mangold wurtzel and succeeding grain crops will become too apparent to leave any doubt as to its beneficial application, and it will be found to answer far better than if the dead subsoil had, by an excessively deep ploughing, been brought up by one operation only to the surface. If farmyard manure is to be applied, it should be first moderately decomposed by fermentation, and carted on at any time in the winter or spring, when it can be accomplished with least injury to the tillage of the soil. As soon after it has been spread, the artificial manure should be sown by hand upon it in each furrow, and immediately ploughed in, taking care not to make the attempt unless the weather and state of the soil are both suitable, and never venturing to bestow the artificial manure unless it can be directly ploughed over. The land should then be suffered to remain until the time of drilling or dibbling in the seed; by no means, if possible, stirring it near that time, so as to allow the moisture to evaporate. It is by adhering strictly to this principle that a plant can with certainty be secured; whilst, on the contrary, by continuously stirring the soil until late in the spring up to the time of sowing, it will probably be lost, unless frequent showers happen to fall at that period. Upon the strong clay homogeneous lands of Essex, which can scarcely be exceeded in tenacity, very fine crops of this valuable root are produced. The practice pursued is, soon after the wheat crop is cleared, to plough in deeply, by one ploughing, about 20 cart loads, 36 bushels each, of good farmyard manure; the long dung, direct from the yard, being preferred. The land then remains untouched until the month of April, when it is scarified and harrowed (not again ploughed), and the seed is drilled in three rows, upon stetches of 6 feet 6 inches each in width; and under this simple mode as fine crops as I have ever seen are produced. The wheat eddish selected for the purpose is, as before stated, where clover had been taken in the previous year, and the after-cultivation of the land is principally carried on by the horse-hoe. The difficulty, however, in carting off the crop in wet seasons is very great upon such soils, and various modes of removing it have been resorted to, sometimes by panniers and horses; but the cheapest mode is by carrying it off in baskets, which it is stated can be accomplished for one shilling per ton, when stored at the sides and ends of the field, and sometimes in a continuous row also in the middle, it can be afterwards removed during a frost, or as best can be effected when opportunity offers for employing the teams to advantage. Although it is at all times necessary to produce a fine tilth at the surface, a considerable degree of firmness is requisite to ensure a full crop. To fully effect this object the land ought to be rolled down with a roller sufficiently heavy to consolidate the soil without kneading it, but this ought not to be attempted until it has become sufficiently dry to accomplish the work safely. If, on the other hand, the weather continues moist, the rolling will be best effected by a roller of a lighter description, such an one as is used for turnips being sufficient. Planting is best performed by the drill, taking care that the seed is never deposited more than one inch in depth. If the land is in a very moist state at the time, and the weather showery, it is better to leave it untouched, after depositing the seed by either harrows or drill. A light bush-harrow may, however, under such circumstances, be adopted. If the weather is dry and the surface of the land also, an extra rolling should then be given immediately after the seed is deposited, which by some cultivators is previously soaked from 24 to 36 hours. This is, notwithstanding, at all times a hazardous practice; for if the land is moist, the soaking of the seed will not be of any advantage; and if nearly dry, the moisture remaining not being sufficient to facilitate vegetation the seed will be likely to rot or mould, and fail in vegetating. Again, if the seed be new, which is the main object to secure success, little doubt can exist that success will follow; for although seed will continue to vegetate until three or four years old, it never does so freely, unless a superabundance of moisture is already present, and the weather continues mild and showery. The process of dibbling is so simple as hardly to require description. The dibbler proceeds with a wooden dibble, having a rather blunt point, and turned with a shoulder, to prevent its entering the soil more than one inch. From two to four seeds are deposited in each hole, and afterwards covered in by the dibbler himself, or by a boy following, who with the back of a hoe punches in the soil firmly on the seed. This, however, may be varied, by the man proceeding with the hoe, and removing a little of the soil, by drawing it with the blade of the hoe towards himself; a boy on the opposite side of the row drops the seeds on the space from which the mould has been withdrawn. The man then immediately pushes the mould back over the seed, and gently presses it down; and as each capsule contains from two or three seeds, they by this process become more dispersed than when dropped into a small hole, and can be more easily singled out afterwards. From 3 to 4 lbs. of seed per acre is found to be sufficient, provided, as before stated, the whole of the seeds are of the previous year's growth; which is however very rarely the case, unless the seed is purchased of persons upon whom dependence can be placed. It is also frequently spoiled by mice extracting the seeds, with but apparent little

injury to the capsule, and which inexperienced persons would not be likely to detect. I am induced to draw particular attention to these facts, as I believe that the causes of failure depend mainly upon defective seed being used; and I do not recollect a single instance in which I have failed in obtaining a plant when I knew that the seed was new and had been well preserved, which, if perfectly dry, may be done by keeping it in casks, or suspending it in sacks from the roof of a building. If a quantity of seed, however, is left exposed in granaries infested by mice, in a few weeks they will extract every kerne from its outer case. The distance at which I plant my roots is 15 inches apart in the rows, and 32 inches apart from row to row. As I now use my roots as early as the month of August, I, for that purpose, have them left about ten inches apart, and by withdrawing each root alternately but little loss ensues to the main crop. This is a far better practice than that of removing part of the leaves, which is very injurious to the after-growth. By the middle of August in the last year, I was enabled thus to obtain from 12 to 15 tons per acre of roots and leaves together, without any material loss in the crop. As soon as the young plants appear, which in favourable seasons takes place in a few days, they should be inspected; and if it is apparent that they decrease, the land ought to be again rolled. The wireworm is sometimes very destructive, especially when land in the previous autumn was covered with grasses; and if seedling weeds are found to spring up abundantly, the ground ought to be at once carefully hoed, and the weeds eradicated from the close vicinity of the plants; for if they become once choked by weeds at this season of their growth, they rarely recover the check thus received. As soon as the plant arrives to three or four inches in height, they should be singled out by hand, taking care to secure the best plant first in the left hand, and then to pull out the superfluous ones with the right; but, if drilled, the plants should be set out first with the hoe, and afterwards singled by the hand, as in the former instance. After the plants have been singled out and the tops of the ridges carefully hoed, a horse-hoeing should follow, which, from the land having been previously subsoiled, will be easily effected; but, if the land has again become consolidated in the furrows, another process of grubbing, or subsoiling, should take place, to enable the horse-hoe to enter the soil readily. Subsequent hand and horse hoeings will also become necessary, and should be frequently applied; and, as the plants advance in growth, the hand-hoeing should be so managed as to draw the soil *from* the roots towards the furrow, so that at the expiration of the season the land will have become nearly level. Great care should be taken to have every plant standing singly, and at all times kept perfectly clear from weeds. All plants that run up with a seed-stem ought to be instantly pulled up and conveyed to the live stock, as they never afterwards form a good root, but greatly impede the growth of those that stand nearest them. The manure best adapted is guano and superphosphate of lime combined; an admixture is invariably found to answer best. This root is a gross feeder, and can hardly be supplied too abundantly with manure; so that, after the land has been properly prepared, it becomes a matter of calculation to what extent manure can be applied, to afford the greatest return of profit in the ensuing crop. As this plant is of marine origin, salt is necessary to its full development. I have generally applied the salt at the time of subsoiling, between the ploughing that precedes and the second ploughing that follows, so as always to bring the subsoil into immediate contact with it; from two to four cwt. per acre is sufficient. I have used the latter, but have lately found that a repetition of that quantity within two or three years is too much, two cwt. being afterwards quite sufficient for the succeeding dressings. I usually apply from 8 to 10 tons of good, partially decomposed farm-yard manure, upon which, when deposited in the rills, I broadcast four cwt. per acre of rapecake, pulverised and mixed with two cwt. of guano and one of superphosphate. If the land is not very good, I add another cwt. of guano or artificial manure. At the time of drilling-in the seed I drill-in one cwt. of superphosphate of lime with it, to force a quick growth of the plants in the first instance. By this mode I usually obtain a good crop, and in using any substitute for the rapecake or farmyard-manure adopt some sort of artificial manure containing a large amount of animal matter. By increasing any of these substance. I feel convinced, from practice, that a larger quantity than three cwt. of guano cannot be applied with advantage; equal to adding, in point of expense, an equal value of some other description of animalized manure. Fish and blood manure are both well adapted, and near the sea-coast, wherever fish can be procured, it may be applied in preference to any other description. Thousands of bushels of star-fish and sprats are annually used for this purpose, which are purchased at about 6d. per bushel, and, in point of cheapness, surpass most descriptions of artificial manure. It is usual to plough them in preceding the winter, merely scarifying the surface afterwards at the time of sowing. During its growth it is seldom interfered with by insects. Slugs and wireworms attack it in its early stages of growth, as well as the common turnip-fly; bat the latter only injures it to a certain extent. By sowing early, however, it sometimes becomes greatly injured by frost, and is sometimes killed if the frost is more than usually severe. Besides, as before mentioned, it has a disposition to run to seed, which induces me to suggest that about the middle of April is the proper time for sowing the main crop. Much, however, of a successful result depends upon the weather that follows, and a due preparation of the land previously. Hot and dry summers especially promote its growth. It rarely suffers from drought; whilst on the other hand excess of moisture and a low temperature combined retards it greatly, and the quality becomes also depreciated in like proportion. After the crop has arrived at maturity it is carted from the field to the homestead, or is stored near to the spot on which it has grown, as the farm-horses are in greater request at this season than at any other portion of the year. It is usual to secure it as near the field as possible, keeping in view the contiguity of a good road, as necessary for its after-conveyance to the homestead. Having determined this point, it is usual about the middle of October to commence pulling and storing it. The roots are pulled up, and the leaves merely twisted off. The former are thrown at once into carts, and removed to their destination. The usual price is 8s. per acre, inclusive of unloading the roots and packing them. The drivers are found by the owner. This amounts to about 4d. per ton, but the price paid depends in some measure upon the state of the weather, the weight of the crop, and the quality of the roots; for if of a bad sort, they will require to be grubbed up by some implement, in which case the cost might be doubled or even more. It is advisable to commence stacking the roots upon a base not exceeding three yards in width, but from 6 to 7 feet is better. The roots should be packed with the crowns outward, in the form of a roof, diminishing upwards until they arrive at a narrow ridge at top, rising from the base from 6 to 8 feet in height. If a wider base is selected it will be necessary to introduce a fagot upright in the middle of the heap at about every 6 feet apart, so as to carry off the heat; for should fermentation set in, which in some seasons it is apt to do, unless due precaution is taken to prevent it, the result would be to spoil the roots. When the clamp or row is completed, it should be well covered over

with straw, about 6 inches in thickness, and then with the soil dug up immediately around to the thickness of about 8 inches, leaving an opening over each fagot secured at first partially from frost by a wisp of straw only. It is, however, thought advisable by some cultivators to defer earthing the heaps to the top for about 2 feet downwards, until a later period, and all hazard of fermentation is over. When it is stored in a building made secure from frost for the purpose, but little further care is necessary, as I have never known an instance of its being injured by fermentation, provided the top of the heap on remain uncovered. In my storing house I frequently cart in from 400 to 500 tons in one heap of 20 feet in width. The walls are formed of the earth excavated; a roof with a thick coating of thatch covers the whole, and the carts enter by folding doors at one end. It may be safely packed to any thickness and height, if afterwards protected only with straw. For this purpose barley straw answers best, and is packed round about three feet wide, and well trodden down, and afterwards thatched over down to the surface. In pulling the roots preparatory to removal it is necessary to take due precaution against injury arising to them by the action of frost, a very slight degree of which will, if they are exposed after being removed from the soil, cause them to rot. That portion of the root which has previously grown beneath the surface being extremely liable to injury when exposed above it, the better way is to pull and carry them direct from the field to the store, and there will be no necessity to remove the soil from the roots further than it can be effected easily, as it readily parts from the roots after storing, whilst by remaining upon them it tends to keep them from fermentation, which however never injures them if the heat is not confined in the heap by the earth applied as a protection from frost. This root is peculiarly adapted to heavy and moory land. It will also flourish upon all loamy soils, upon which Swede turnips succeed well. In most cases it will produce from 18 to 22 tons per acre, but with extra cultivation and management about 10 tons per acre more. The quantity per acre can be easily ascertained by weighing one load carried by each cart employed; and by filling the carts alike the quantity may be obtained. Measuring a single rod, and computing the weight per acre by it, at all times is a fallacious mode. Great errors are sometimes made by it, as much as 25 per cent. less having been afterwards detected by computing by this method. A row taken and weighed from two or three average portions of the field would give a result sufficiently near. The weighing of a single rod to ascertain the comparative *weights* of different varieties is, however, the best mode; as the quantity in imperial stones per rod is equivalent to the like number of tons per statute acre of 160 rods. There being 160 stones in one ton, this mode is exceedingly well adapted to obtain the weight of the produce per acre. The weights per rod grown by myself in last season were as follows:—

		cwt.	lb
Red globe.....	strong loam, weighed	4	32
Long red	ditto	3	96
Yellow globe....	ditto	3	90

Upon tender loam the yellow globe produced 4 cwt. 4 lb., the other varieties not being weighed. In every other instance of weighing in previous years, the long red variety was invariably the heaviest. It has also other advantages, being more easily pulled and stored. The quality I consider about equal. Cattle, however, will select it from the orange-coloured in preference, and hares and rabbits also. Some of my land at one time joined a game preserve, and I then found that during the early growth the orange varieties were not much bitten, but that the long red, on the contrary, were always very much injured. Having described the mode of producing, I shall now advert to the best mode of expending this root, so far as my own observation and experience enables me, and having now used it forty years, I have no hesitation in giving it the preference to every other description of root or vegetable, not only as regards the amount of produce, but as to its general applicability. For fattening neat stock it is superior to the turnip. For breeding sheep and cows, however, I think the latter better; but as the season advances, the mangold wurtzel becomes greatly superior, improving the longer it is kept in the spring, whilst turnips depreciate in about equal ratio. Where cattle have been accustomed to it early, they never become affected by it afterwards; but it frequently happens that other neat stock and sheep, upon having their fill, at once become affected. It apparently attacks the nervous system, and produces stiffness of the joints, and they refuse to eat it for a few days; but all this may be obviated by feeding them moderately upon it at first, increasing the quantity daily, and always combining it with cut chaff or other dry food. I introduced this mode on a former occasion to the notice of this club, and have since found it has been generally adopted. The mangold root, when first drawn, contains an abundance of water, and requires dry food in admixture to counteract its effects upon the bowels of the animals. It can be also adjusted better as regards the quantity given per day; from 56 to 112 lbs. being fully sufficient. About the middle of January the second vegetation commences, and the sugar it contains becomes fixed, and cannot be extracted. From that period, the fattening properties become greatly augmented, and continue to increase until the month of June. I use machines that pluck it into small pieces; these are mixed with a quantity of cut chaff, composed one-third part of hay and two-thirds oat or wheat straw, moistened by linseed meal, that has been steeped in water forty-eight hours, at the rate of 3 lbs. to each bullock. In addition, from 3 to 4 lbs. of barley or bean meal are added at the time of feeding; each meal being prepared twelve hours previous to using. For store stock about 56 lbs. (equivalent to one bushel) is given; for fatting stock from 80 to 112 lbs. per diem. I keep a large number of milking cows, which are fed upon it from August to June following. Whenever the leaves can be used we find an increased quantity of milk. They are invariably cut up, and mixed with the roots and chaff, and are the most valuable portion of the plant in its early stages. As a manure, when ploughed in, they are also beneficial; but where much live stock is kept they can be applied to a more beneficial purpose. In feeding sheep, as well as cows, the roots are best when combined with cabbages or turnips, but should never be given to either without some degree of caution being exercised, as a sudden change of food is apt to cause considerable relaxation of the bowels, which can be mostly avoided by proper management. For sheep before lambing and for sows in farrow they cannot be recommended, and for very young pigs they are also not well adapted, but are even injurious. The roots produce great heat in the system, and even oxen will during the most severe frosty weather be found in a high state of perspiration in open yards, and young cattle invariably fatten upon them far better in open yards than when stalled. This may be accepted as an established fact, having myself made several experiments to prove it. With older cattle it is otherwise. There is one point, however, quite certain, that cattle which have been longest accustomed to mangel wurzel thrive best upon it, and for youn

weaned calves of two or three months old it succeeds admirably; still, whenever it can be combined with swedes or common turnips, it is advisable to do so. I may appear prolix in these descriptions, and to the experienced farmer much will appear to be a repetition only of his previously acquired information; but from the number of inquiries I from time to time receive upon the mode of cultivation and application, I am induced to believe that the public in general are not acquainted with either. Indeed, in many districts it has not yet been introduced, whilst in many others only recently, and but in few has it been extensively brought into cultivation. The yield per acre will depend in a great measure upon the means employed, the increase being for the most part dependent upon the state of the soil and the quantity of manure applied. It must, however, be obvious that, after the land has been brought into the necessary state of tillage, the next question is to what extent manure may be applied best to facilitate the object. It becomes merely a calculation whether an extra ton of manure will or will not produce a corresponding return in weight of roots. So far as my experience has been confirmed I have found that by an extra application of 1 cwt. of guano, of the cost of 14s., from 4 to 5 tons increase of roots may be produced, and so of most other descriptions of manure in like proportion. Some curious particulars respecting it a few years since were accidentally obtained. At a sugar manufactory established in Essex it was found that the sugar could not be extracted after the second vegetative process had commenced in the root. This circumstance to some extent explains why the roots at this particular period are of a less laxative quality and greater fattening property. Mangel wurzel contains about 5 per cent. of sugar which has been extracted and manufactured profitably by the French for a long period of time, but recent attempts made in this country have not been attended with like successful results. The Silesian beet has been used more especially, but it is a question, taking weight into consideration, whether it would be more profitable for that purpose than our orange-coloured mangold. Some years ago, observing it in process of drying upon a kiln devoted to the purpose of drying chicory, and doubtless as a substitute for that root, it struck me that in this state it would produce good beer, the dried root acquiring a malt taste, and the moisture of the root being driven off by the process of drying. I made various experiments, and have produced a good beverage, very similar in colour and character to London porter; but I am free to confess that the workmen in my employment, having acquired a peculiar *relish* for malt beer (Hear, hear), cannot be induced to accede to its adoption at seasons when they assume the dictatorial position, especially during harvest (loud laughter). The process, however, is so simple, that I will repeat it here, and offer you a sample whereby you will be able to judge of its quality. The roots should be sliced with a Gardner's, or other turnip slicer, about three-quarters of an inch in thickness and about one and-a-half inches in width. These should be dried slowly upon a kiln, until quite crisp, taking care not to scorch them during the process. Three bushels of these dried roots are about equivalent to one bushel of malt, and should when placed in the mash tub have boiling water poured upon them, so that when drawn off it shall produce one hogshead of sixty gallons. This liquor should be boiled from one hour to one-and-a-half hour. Then add hops equivalent to 3 lbs. for each hogshead, and boil 15 or 20 minutes longer; ferment the wort at 65 to 70 degrees, and treat it exactly as in the case of malt liquor. Keep it at least eight months before using; but at 12 months it will be quite ready for use, and will then keep 12 months longer with advantage. Nine bushels of the roots will be equal to three bushels of malt, and sufficient for one hogshead. The roots will not be much deteriorated by the process of brewing, cattle eating them with greater relish than before. The cost per hogshead will be about 10s., or sufficient of the roots may be cut into pieces and put into a copper until full. As much water may then be added as the copper will hold. When it has boiled long enough for the roots to become tender, the liquor should be strained off, and sufficient hops added, and again boiled one hour. Ferment and turn as before. Although this plan is attended with less trouble, the former is far preferable, as the process of drying drives off the watery portion of the root, by which an earthy flavour is got rid of, and, the root becoming malted, assumes the flavour and quality of malt produced from barley. Every one who has the slightest acquaintance with the science of chemistry must be aware that any substance that contains sugar will produce fermented liquor, as beer, which upon distillation will yield alcohol or spirit. Sugar, however, being presented to us in the form it has acquired by the processes of manufacture, is scarcely reconcilable with the opinion entertained of mangold wurtzel by the majority; and it is very probable that the sap or juice extracted from the sugar-cane differs in its first stage but little from that extracted from mangold wurtzel. Be this as it may, prejudice can rarely be overcome, with the lower classes, in any matters connected with their food and drink, however great an improvement may take place (Hear, hear, and a laugh). To those who may wish to grow their own seed, it will be only necessary to state that, after the roots have been properly selected, they should be protected from the action of frost until the following March, when they should be planted out about 18 inches apart, protecting the upper portion of the root from after-frost by coal-ashes. The shoots, as they advance, should be supported by stakes, and carefully preserved from the attacks of small birds, especially sparrows, which will, if seed is attempted to be grown on a small scale, most probably destroy the crop altogether. In concluding, I beg to observe that I have adhered throughout to the broad principles of cultivation, as carried out by myself, leaving to others particular systems for discussion; and I have avoided throughout introducing anything but what has resulted from my own practical observations. Since I completed my paper, I have received a communication from a correspondent (Mr. Stagg, of Grafton, Wilts), who has grown and used this root largely. He states that he believes it was not at one time much appreciated: but that the prejudice is wearing fast away, since the application of it has become better understood. He states that danger from overfeeding must be avoided; that the root should be treated rather as an auxiliary in feeding than otherwise; and that 56lb. per day for store cattle and 70lb. for fatting cattle is sufficient; that in feeding ewes he does not allow them more at once than they will eat in three-quarters of an hour. For lambs and tegs, he thinks about two bushels of cut root per score sufficient for one day, increasing the quantity to three bushels per score, and, as the spring advances, even more; and he then, in adverting to its feeding quality, states that its nutritions property consists of saccharine, which he erroneously supposes to decrease as the season advances, because it cannot then be extracted for making sugar. Upon investigation, however, such does not appear to be the case. The sugar undoubtedly remains, but becomes fixed, so as not to be extracted by the usual modes. It ceases to crystallize under the ordinary process; but that it remains un-

diminished in quantity, is certain. The root, during the spring, loses a large proportion of moisture. The quality becomes sensibly altered, and the sugar has also undergone a chemical change, which causes it to act upon the intestines of the animal less violently than in its early stages, and which, as I before stated, may be altogether avoided by combining it with dry food, and giving it in moderate quantity. Cattle, however, that have been fed upon it from an early age, are never observed to become afterwards affected by it. Some discussion has taken place upon its being injurious to sows in farrow, and to very young pigs, which, although not invariably the case, ought to be obviated. I prevent it as much as possible by sending them away to a yard where it cannot be obtained, but for pigs from four to twelve months old it is highly beneficial. I also object to giving it to the ewes in lamb, as I have sometimes found that it has been attended with bad results, and, as a general rule, ought to be avoided; but wherever it can be combined with other descriptions of roots or cabbages it is excellent. Horses can be fed upon it with advantage, and in small quantities daily it may always be successfully used. By a statement I received from an intimate friend, the result of such a mode is given by him as follows. The horses I inspected, and they certainly appeared in healthy and good working condition. Expense of keeping 8 horses for 18 weeks at, per week, £2 6s. 8d. 2½ bushels each horse per day at 4d. (the exact cost per bushel), or 5s. 10d. each horse per week. One and-a-half bushel when at light work, 4s. per day, £1 8s. per week, or on an average £1 17s. 4d. per week. The roots were given whole, and the horses had sufficiency of good oat straw in addition, which, at 1s. 6d. each, is 12s.; altogether £2 9s. 4d. per week. Eight other horses, at one and-a-half bushels of oats each horse per week, is 12 bushels, at 3s., £1 16s.; half ton of trussed hay in addition, £1 10s.; average per week £3 6s.; so that the keep in one instance was £2 9s. 4d. per week, in the other £3 6s.—in my opinion, not sufficient profit to enable it to be adopted, especially upon farms principally arable, where the manufacture of manure is of great consideration. Six oxen might have been maintained in addition to the horses, which would have produced double the quantity of manure, a point worthy of consideration as an adjunct. However, in feeding horses, not exceeding 1 bushel per week to every horse becomes beneficial in the highest degree to the health of the animals. In conclusion, I wish to add, that upon a fair calculation, mangold wurtzel is a crop that may be produced more cheaply than swede turnips, or any other description of cattle food. Upon our light turnip soils it cannot be introduced with advantage, nor will it ever in such situations be accepted as a substitute for either the swede or common turnip, especially as it cannot be folded off by sheep upon the field where it has been grown; but for yard feeding of sheep I believe it to be superior to the varieties of turnip. Upon mixed soils and strong clays, too heavy for the cultivation of the turnip, it has opened a new system of cultivation, enabling the occupiers of farms, upon which 30 years ago no cattle food was obtained in the winter, to fodder out their straw and hay with great advantage; and since the introduction of guano and artificial manures it may be grown almost to any extent without depriving the farm of the ordinary manure. In the autumn, from the beginning of October, the pulling and storing the crop may be commenced whenever the leaves may be required, pulling the roots no faster than they may be required. So far as my experience goes, I believe they may be estimated at from 30s. to 2*l*. per acre. My mode is to cut them with hay, and the short straw coming from the thrashing-machine at that time. Large store hogs, with a moderate quantity of peas or beans may be fattened to a certain extent upon the roots, so as not to require much meal in addition afterwards; but the meat will not be of first rate quality if no meal is used in addition. One word I wish to add upon the cultivation. The land cannot be too frequently stirred, even if weeds are absent; but in hoeing, if the roots are cut with the hoe from inattention, it always injures them, and frequently spoils them altogether. Another very important point is the quality of the roots, and which cannot be obtained unless the seed has been well and carefully produced. Cheapness is the order of the day, but in no instance does a farmer pay more dearly than when he purchases seeds of indifferent quality; but in seeds from which our roots are produced, which at most amount to only a few shillings per acre, the crop has varied from 100 to 300 per cent.; whilst invariably the soil is injured to a far greater extent by the worst variety. Wheat appears to be the best crop to succeed, if the land can be cleared with little injury. It will require, however, a light dressing of manure at the time of sowing, or a top-dressing in the spring of 40 bushels of soot per acre, if it can be procured, to be applied when the weather is open and moist, early in the spring. The broad leaf, or red clover, succeeds better after it than after any other crop; and I have known instances of wheat and mangold-wurtzel being grown in rotation for many years together, and probably with as large profitable return as by any other system of husbandry. By way of addendum, I will give the cost of brewing beer from it exactly as carried out by myself, for the instruction of those who are desirous of making the experiment. Although brewing from mangold-wurtzel has been referred to in the foregoing description, I may observe that beer made from Silesian beet is far preferable, and more nearly imitates beer manufactured from malt, and is not so liable to become flat after the cask becomes partially drawn out, or exposure to the air takes place, to which beer from mangold-wurtzel is liable. Five tons of roots produce from 70 to 80 bushels of dried roots, and are calculated to brew as much beer as 4 quarters of barley-malt. A copper that holds 1¼ hogsheads will require about one-third more water to obtain sufficient wort to again fill it. Put 1 hogshead at boiling-heat upon the roots, and mash well; then, as quickly as it can be obtained, add 1 hogshead more boiling water, to be again mashed; let it stand one hour additional, and draw off clear; put on about 1 hogshead of water cold, and in about a quarter of an hour draw off. This liquor should be put in the copper, and boiled for the next mash; take out the roots, and replace with a like quantity as before for the second brewing; boil the wort for one hour, then add 5 lbs. of good hops, and boil twenty minutes longer; ferment at from 65 to 70 degrees, as with malt-beer; tun, and keep it eight months before using: it will, however, keep two years, and continue to improve, from 6 to 8 bushels of the roots being sufficient for each hogshead. The roots may, after being used for brewing, be given to cattle or swine, with but little loss in quantity, but certainly of improved quality. One ton of roots produces about 15 bushels of dried roots; the cost of drying being 5s., and slicing about 2s. more; the whole cost of the beer is 10s. per hogshead.

Mr. W. Bennett (Cambridge) regarded the subject, however, of how best to grow, to store, and to use mangel wurzel, as of paramount importance, more especially at the present day, when in many parts of the kingdom Swedish turnips had become almost an utter failure. This root had long become the staple article for the fattening of cattle in almost all parts of the country, but had of late years become subject almost to endless diseases. He could speak particularly of his native county (Bedfordshire), Herts,

Hunts, and Cambridgeshire. The crop of swedes was not only now blasted, by a great variety of insects, by the very frequent occurrence of the disease called an-berry, or the finger-and toe disease, but also by a complaint similar to the potato murrain; the bulb decaying most near the root, and at other times it would commence at the very heart of the turnip. Nor was the disease at all confined to certain unkind lands for turnips, but on the best convertible soils, and those under the very best management. Our farmers could no longer depend upon any part of those crops to draw off for stall feeding; but sufficient could not be grown even to furnish manure for the succeeding crop of barley, where all the turnips were fed upon the land. It was that circumstance which rendered Mr. Baker's able paper so much the more valuable, for it was a startling fact that while they had rarely known a more wretched crop of turnips, the mangold had proved this year splendid almost beyond precedent. Mr. Baker's remarks on the culture for mangold were very judicious: his practice in some respects was very similar to his (Mr. Bennett's). His own plan was to plough deep in the autumn, often two furrows deep, or plough one good deep furrow, the subsoil-plough following; but where the subsoil was at all strong and good, he preferred ploughing two furrows deep, throwing the lower soil at top, for the action of the atmosphere. For his own part he preferred getting the land ultimately into Northumberland ridges, although he knew on the strong lands of Essex and part of Suffolk our best farmers succeeded in growing admirable crops on the flat surface, by one deep autumnal ploughing (cheers). The great superiority of mangel wurzel over most other roots was, first, that it might be grown on land unkind for the growth of turnips; secondly, such lands would bear a much heavier crop; thirdly, it was far more easily extracted from the soil; fourthly, it might be kept much later in the season; and last, though not least, if fed judiciously with other food, it was equal if not superior in its fattening qualities to the best kind of turnips (Hear, hear). The cultivation of mangold had in fact opened a new era in clay land farming. There were many farms in his native county, on the northern side of it, where decent flocks of sheep were kept in summer; but not being at all adapted for turnips, the flock had to be disposed of, in the winter, except a few half-starved ewes, which ran over the grass land in the day time, and browsed the bean-straw at night. By the cultivation of mangold, however, in these modern times, fine flocks of ewes were now kept where scarcely any could be kept before. Also on fen land, which was admirably adapted for the growth of mangold to the extent of 30 to 40 tons per acre, this root was now grown extensively, and although not equal in quality to that grown on high land, it was by no means depreciated in the same degree as were turnips on this kind of land. On all soils salt greatly improved the quality of mangold, and he felt confident on none so much as peaty fen land.

Mr. THOMAS (Lidlington, Beds) said that Mr. Baker had not alluded to a circumstance with which he (Mr. Thomas) had some slight acquaintance, viz., to the seeds being wrapped in capsules, each of which contained three or four seeds. He should like to know whether Mr. Baker had ever tried the experiment of breaking up the capsules (Hear, hear). He (Mr. Thomas) had done so on a small scale in his garden, he had crushed the outward coat through a bean-mill, and he had found, in consequence, that the plants came to the hoe in one half the time that those did which were dibbled in the capsules. One remark which Mr. Baker had made was susceptible of correction. That gentleman had stated that there was this difficulty with regard to mangold-wurtzel, that it could not be fed off the land in the same manner as the swede turnip. He (Mr. Thomas) begged to assure him that so far was that from being the case that in Bedfordshire it was becoming a very common practice indeed to eat it off the land.

Mr. BAKER: You could not produce a heavy crop, then?

Mr. THOMAS begged pardon; he had seen very heavy crops of mangold on light lands. He had seen this on sandhills which had become sick and tired of growing swede turnips. Mangold-wurtzel could be eaten off the land about the months of March and April, and he believed it was more forcing and nutritious than the swede itself at that time of the year.

Mr. STAGG (Grafton, Wilts) said that, like Mr. Thomas, he could not agree with Mr. Baker in all the views he had enunciated on this subject. In the first place, with regard to mangold-wurtzel not being a proper food for ewes, lambs, and pigs he himself had fed his flocks of ewes and sows for many years past, from the month of November to the month of May, upon that description of root, and he had had quite as good lambs as any of his neighbours who had fed their flocks upon turnips. His tegs also had fed upon and done well thereon; so likewise had his sows to a great extent, and he should not be afraid to show them against those of any gentleman in Bedfordshire. They had had very good farrows, from ten to thirteen at a time; during the whole of last winter he never lost a pig, and he believed he had about a hundred now. With regard to storing of mangold, his practice was to store in heaps of about a cart-load each, first cutting off the greens or tops which are left on the land, and fed by ewes. About two-thirds of the roots are then fed on the land by sheep, the remaining one-third (more or less as required) carted off when convenient, and given to cattle or pigs in the farm-yards. The only objection he ever found was the difficulty in preventing servants over feeding with this root. The store-heaps are covered with straw in the same manner as potatoes. He had a large field now in store of, he believed, fully 40 tons per acre, and had never had a wheelbarrow-full of rotton mangold throughout the whole of his experience.

Mr. WILLIAMS: You don't cut them near the crown?

Mr. STAGG: No, not so near as to run the risk of injuring the crown. With regard to mangel wurzel as a root crop, he considered it most valuable for the farm. On one part of his farm he had grown turnips, but those were to a great extent club-footed, and were what had not inaptly been termed fingers and toes (Hear, hear). Upon heavy clay soils and upon sandy soils that would not grow turnips, it was, in his opinion, quite a godsend to have mangel wurzel to resort to; and he would repeat that he considered it a most beneficial crop for the farm. He had kept 600 sheep for the last 15 years, on the average, although they had scarcely any other kind of roots than mangel from November to March (Hear, hear).

A MEMBER: What sort of a farm is yours?

Mr. STAGG: A store and corn farm.

The MEMBER: And what kind of mangel wurzel do you prefer?

Mr. STAGG: The red globes (Hear, hear). In conclusion, he would merely observe that there was no more difficulty in feeding off mangel than swedes (Hear, hear).

Mr. GRAY (Courteen-hall, Northampton) did not presume to set his production of mangel wurzel in competition with that of Mr. Baker, but having had some years' experience in the growth of this root, he would take the liberty of making a few remarks with regard to the system he had pursued. Of course, he grew it after his white grain crop. After harvest, if the land wanted cleaning, he did what he could to accomplish that object. He then manured with from 10 to 12 tons of dung per acre, leaving it spread upon the land

for two months, ploughed it up to a fair depth, and left it until the spring. April was in his opinion the best time for sowing. He set two ploughs to ridge it up, and dibbled the seed in, employing four men for that purpose. Each man carried a little bag of seed hanging from his neck, and dropped in the seed as he went along. He made a compost of turf ashes, malt dust, and pigeon manure, with three hundred of superphosphate of lime per acre. This he mixed up and left to lie a little while before he required to use it, and carried it to the land in carts, and afterwards along the ridges in wheelbarrows, putting a handful of the compost over the seed, that being the covering it had. He should also state that upon depositing the seed, he applied a light roller. Since he had tried this system his crop had never failed, but was always a very good one, although it had failed under every other system. With regard to the transplanting of mangel wurzel, they all knew that if they did not get a full plant it might be desirable to transplant. His own practice was to get a strong force of men and boys, and on the first wet day send them out to transplant his mangold; but let it be observed that if the operation was performed in the same manner as they treated the cabbage, they would get no plant. He put in the little fibres straight, and pressed them down lightly with the soil; for the lighter they were pressed the better. During the present year, he had been particularly successful. He had transplanted more than at any former period, and finer crops he had never grown. The discovery of this fact he had made quite by accident, and he was sure it was worthy the consideration of the farmer. With respect to horse-hoeing, they all knew the advantage of keeping the land well and thoroughly cleaned (Hear, hear). When he took up the roots for storing he set two men with common bean hooks to cut the tops off, and he did not think that out of 10 acres of mangold wurtzel last year he had a single decayed root. This at all events showed that cutting off the tops was not injurious. Then, as to storing, he set four men to fill the carts. Boys were employed to drive the carts away, and it took two men to put the roots in heaps. He thatched as rapidly as the heaps were formed, leaving plenty of ventilation. With reference to the value of the root, he thought it was becoming more important every year. Certainly its feeding qualities were unsurpassed by those of any other. He once showed in Baker-street a Hereford ox, the only root he had being mangold wurtzel, being the winner of the first prize in class 2. Some remarks had been made about the difficulty of growing mangold wurtzel on stiff soils. He himself on one occasion tried the cultivation of it on as stiff a soil as any in England; and he should pity any man who was obliged to produce mangold upon that sort of soil. The system which he adopted was to cultivate in the autumn, manure, ridge up, and then leave it. By adopting that plan very good crops might be grown on such soils, and it was practised very extensively with great success on the cold clay lands of Huntingdonshire.

Mr. W. BENNETT: Do you prefer large plants for transplanting?

Mr. GRAY: Not very large.

Mr. BENNETT: As large as a cabbage plant?

Mr. GRAY: No.

Mr. THOMAS wished to say one word with regard to feeding ewes off mangold wurtzel. For more than 25 years he had invariably done it, and during the last month previous to yeaning, had always found it to be most beneficial. After trying the system for many years, he made a memorandum of the result of his practice to this effect—that there was no kind of food so suitable for ewes during the last four or five weeks before parturition as mangold wurtzel (Hear, hear). He could assure every gentleman who grew mangold wurtzel, and possessed a flock of ewes heavy with lamb, that he had never found the least injurious results from the practice, but, on the contrary, very great advantage in the production of fat and milk at the same time.

Mr. GRAY said that on one occasion, when he was not so well acquainted with its feeding properties as he was now, he had a considerable quantity of mangold down in the month of July, and felt some difficulty in deciding how he should dispose of it. At last he fetched in ten bullocks from the field, and gave them the mangold, with a proportionate quantity of hay, and the result was that he had never seen beasts do better (Hear, hear).

Mr. COUSSMAKER (Westwood, Farnham) said, as regarded the cultivation of mangold wurtzel, he concurred in the opinion of Mr. Gray, that it was desirable to plough deep once in the autumn, and then leave it. Winter produced a tilth which no power on earth could produce in the spring. The more they stirred the soil in the spring, the more they let the drought into it. If it were left alone, the soil retained a certain amount of moisture, and the seed vegetated quicker. With regard to the stacking of the crop, he agreed with what fell from Mr. Baker. He had used this root a good deal for fattening beasts, and as food for milch cows. He had found the orange globes produce the best kind of milk. He had likewise found mangold wurtzel a most valuable food for store pigs; and, though he had never used it himself for that purpose, he had heard that it was not at all a bad kind of food for horses when mixed with a certain proportion of hay and corn. The long orange was, he believed, a very superior root. Some years ago, a gentleman took a farm near his own for the express purpose of making beet-root sugar; and the sort of root which he chose for that purpose was the long orange. As it appeared that there was an Act of Parliament under which he might be compelled to pay duty on his sugar, he dropped the scheme; but he was of opinion that he might otherwise have cultivated the long orange with great advantage for the manufacture of sugar.

Mr. J. A. WILLIAMS (Baydon, Hungerford), said, occupying as he did some of that stiff land which had been spoken of, he had not yet been able to cultivate mangel wurzel to advantage; but he thought the cause was, that he had not adopted the right method. He was more than ever convinced of the utility of that Club, for he was satisfied, from the arguments of Mr. Grey and Mr. Coussmaker, that to be successful on very strong clays the cultivation must take place in the autumn. He happened to have a good description of down land, and having been told by practical men that such land would grow mangel wurzel, he should be glad if any one present could tell him from experience whether or not such was the case. Mr. Baker had spoken of the practicability of distilling from mangel wurzel. He (Mr. Williams) thought that with the prospect of having wheat at 40s. a quarter that was a matter which was well worthy of consideration; but Mr. Baker had raised an obstacle which, if it really existed, would prevent such a desirable object from being attained, viz., that the landlords would not permit, and the tenants would not like, the cartage of a large bulk of roots off the farm, as it would be too much to draw the bulbs away, and the residue back again for feeding purposes. Now he was pleased to tell them that that obstacle was removed. They had all seen or heard of the invention of Boydell's steam-horse, manufactured

by Mr. Burrell of Thetford. Mr. Burrell had told him (Mr. Williams) that he had taken out a patent for a portable distillery to meet this very case. He did not think landlords would object to the mere extraction of the spirit if the feeding qualities of the roots were left on the farm; and the steam-horse and the portable distillery might go from farm to farm extracting the spirit from the roots (laughter), and leaving the bulk of the crop for feeding purposes or for manure, and possibly paying the farmer for the extract alone a considerable profit beyond the cost of production. This appears to me to be a move in the right direction, for if we are called upon to grow wheat at a low price, which we cannot do, it is worth considering if it would not be wise to cease to a certain extent the growth of that article, and substitute a larger growth of roots for distilling purposes.

Mr. MASON (Somersham, Huntingdon) said his experience had lain entirey among black fen-land, and for fifteen or twenty years he had been in the habit of growing mangel-wurzel on land of that description. He agreed with Mr. Baker that, on light soils, the use of the hoe for the purpose of pressure was very desirable. The pressure which he had used, however, was simply that of the heel. After setting the seed he used a handful of blood-manure, and nothing else; he then resorted to the heel, to secure solidity; and for some years past his roots had thriven exceedingly well under that process. As regards packing, it was of course very important to effect the operation in such a manner as to prevent fermentation. The system which he adopted was this. He invariably mixed his seed, 4lbs. being about the quantity. He used 2lbs. of globe, and 2lbs. of red; and one advantage of this mixture was that, if the one kind failed, as it frequently did, the other still remained to produce the crop. Another advantage of the mixture of the globe with the red was found in the packing of the roots, there being less tendency to fermentation; and, in his own experience, he had sustained comparatively little loss under that mode of proceeding.

Mr. T. CHANDLER (Aldbourne, Hungerford), referring to a remark by Mr. Williams in reference to down land, said that he had cultivated mangel wurzel on land of that description with great success, while his turnip cultivation on the same land was a failure.

Mr. BAKER then replied. Adverting to the remarks made with respect to the feeding of pigs on mangel wurzel, he said he had tried it in the case of his own pigs, and the result was not satisfactory. With respect to the crushing of the capsules advocated by Mr. Thomas, no doubt the moisture would reach the seed all the better for the external coating being broken, but there was a danger of cracking the seed at the same time. He was very glad that so much interest had been manifested in the subject.

On the motion of Mr. THOMAS, seconded by Mr. HARRISON, thanks were voted to Mr. Baker for his able paper; and a similar compliment having been paid the Chairman, the meeting separated.

THE MANAGEMENT OF A FLOCK OF BREEDING EWES, MORE PARTICULARLY IN THE LAMBING SEASON.

"Sheep," said Fitzherbert long ago, "is the most profitablest cattle that a man can have." Since his day so much attention has been paid to the breeding and general management of sheep, and with such encouraging results, that this old writer's statement is more entirely realized than ever he expected.

In the following remarks upon the treatment of breeding ewes I shall not confine myself particularly to one class. I intend to detail the course generally adopted; and if specific treatment is noticed, the locality where it prevails will of course be stated.

We will commence, then, with the *selection of ewes* to put to the tup.

This selection is only necessary where a standing flock is kept. Where the flock is a "flying one," since all are disposed of, none obtain a preference. By a *flying flock* is meant one that is purchased a little before, or immediately after, the lambing season, the lambs being disposed of when weaned, and the ewes, when fat, from coleseed, &c.

The aged ewes, and ewes with no teeth, are first drafted. Some breeders expel every ewe that has had three crops of lambs.

The flock-masters of North Lincolnshire get off their ewes at their fourth year in prime condition, and make topping prices.

But whatever variety of practice there may be, a ewe with no teeth, or defective teeth, where turnips are grown, ceases to be used for breeding, as she would fail to sustain not only her progeny, but herself.

Should the breeder eject from the flock every ewe having a disqualifying property, he might as well give up breeding. Such drafting must, however, depend upon the number of *good* substitutes which the shearling ewes or gimmers may supply, which, of course, have in their turn to be subjected to a rigid examination. First determine the number of gimmers to be admitted, and then draft out of the old flock a corresponding number of the worst animals. Beyond the disqualifications of age and bad teeth, there are some others which I will mention: *thin wool, hollow back, flat sides* (indicating a want of space for the fœtus), *diseased udder, asthmatical affections, and diminutive stature.*

This selection is very important, for with improved form we obtain improved constitution.

Then if the flock is sufficiently large to employ two tups or more, the ewes must be divided into as many classes as there are tups, the breeder designing to correct the defects of the female by the excellencies of the male; and this course perseveringly pursued is always found to result in a regular, sound, and prolific flock.

As ewes are more prolific during their third and fourth years than they are before or after, during which time they generally produce single and weak lambs, it seems that a "flying-flock," could it be obtained of the right age, might be more profitable than a standing flock. There are reasons, however, why such a course is open to objection; but I do not intend to touch upon them now.

The tup commences his work generally on the 11th October, so that the lambs are expected about the 8th to the 11th of March. The date of this operation is varied according to circumstances. For in Scotland the tupping season for Cheviots is from 15th to 22nd November, with the expectation of receiving the lambs in April, when the weather is milder. In the South, where breeders endeavour to supply the London market with early lamb, arrangements are made by which they arrive at Christmas, and from some classes of Dorsets two crops of lambs are obtained within the year. In the north-eastern counties, the north-eastern wind having cut

with such a keen destructive edge, during the last three or four years, throughout the month of March, many of the breeders in those districts have turned the tups to the ewes at the end of October, or the commencement of November. I very much question, however, the benefit received from the change. *One* early lamb is generally worth *two* late ones.

Where high-prized sheep are employed, as in the case of a ram-breeder, another plan is sometimes adopted, for the purpose of obtaining the greatest amount of service from the ram, and more regularity of procedure. The rams are kept in pens, while a *teazer*, or imperfectly castrated sheep, is turned amongst the flock, and those ewes seen to be in heat are brought up to the rams selected for them. They are then numbered with a brand, and a note is made of the date, &c.

Ruddling.—It is well, that the shepherd may know what the tups are about, to mark their breasts with ruddle for the first 17 days they are among the ewes, that being the time of the periodical recurrence of heat, and then to use soot. At lambing time the red-rumped ewes, or those that conceived from the first copulation, are brought into the fold, and the black-rumped ones after the proper lapse of time.

Choice of Food.—About a fortnight before ewes are put to tup, they are removed from the stubbles and bare pastures, and put upon the freshest pastures the farm affords, or better still on rape. Failing rape or coleseed they may be folded upon white turnips, or turnips may be carted to them upon grass. Mixtures of white mustard and coleseed, or white mustard alone, are found very advantageous at this season. When this better fare has begun to tell in their improved condition, the tups are turned amongst them ; for under such circumstances the ewes come to heat quickly, and are more likely to conceive twins. And this quickness to receive the male is more important than at first sight appears, since the ram should be removed in three or four weeks from the date of his admission, because lambs begotten so long after the rest will not coincide with them, are often sickly, and suffer from neglect. For this reason poppy-cake, bruised and served in troughs, is used by some, and other stimulants are adopted.

Ewes are then put upon moderate fare, care being taken to avoid the extremes of fatness and poverty. The poor ewe, if she lives through the season of parturition, dies with her lamb, from exhaustion subsequently, while the fat ewe rarely escapes attacks of fever and inflammation, from which cause she sheds her wool, and fails to nourish her lamb either before its birth or afterwards. They do well run thinly on grass land, 1 or 1½ to an acre, with, when the frost sets in, a few turnips or mangolds carted to them, and a rack filled with hay, pea or barley straw, to run to. When the four-course system is adopted, there is generally a necessity for feeding ewes upon turnips, and they then follow the fatting sheep, to eat up their scraps and shells. This arrangement suits both lots, for Swedish turnips produce fatness on ewes more readily than other kinds. As the lambing time approaches, the ewes should be removed from the turnips to the grass or seed, receiving there mangold wurtzel and a little oilcake or oats. It may be remarked here that too much care cannot be observed throughout the month of February, as to the regularity in time of feeding, quantity and kind of food given.

A scant supply for a day or two, or a total and sudden change from turnips to mangolds, for instance, would be likely to produce serious results in the crop of lambs. Sufficient attention is not paid to this fact. The wool suffers as well as the lambs.

Great care at this time should be taken to prevent the intrusion of dogs ; any cause likely to startle a ewe at this period must be guarded against. Unless the shepherd's dog is a very silent reliable animal, I advise that he should be tied up at this season.

The shepherd must now look out for cast ewes ; for a ewe to be long in this position may endanger her life, or cause an awkward presentation at delivery.

Preparations for Lambing.—*The Shepherd.*—It may be thought curious that I start off, under this head, with the shepherd ; but as upon his qualifications depend so entirely the welfare of the flock, it is of the greatest consequence that we have the right man in the right place. There is no season like the lambing season for trying a man's tact, knowledge, and patience. During that season only, the skilful attentive servant may save his year's wages ; and the comparative results between the skill and attention, and inattention or blundering assiduity, during a precarious time, are truly astounding. Mr. Price and Mr. Youatt, both writers on sheep, seem to regard as natural and proper treatment on the shepherd's part many things that would display a lamentable amount of ignorance and incapacity quite incompatible with the burden of such a responsibility. One instance is given by Mr. Price, of a flock of 800 ewes out of which only 100 pairs were saved ; but that with more skill the number of pairs afterwards increased to 200. The improved skill of one man then saved 200 lambs, which would come to be worth £200, equalling the wages of at least four good shepherds ! The shepherd's duties are no sinecure, and can be performed by no ordinary man. Supposing him to have attentively observed the tupping and registered the ewes, and in conjunction with his master so regulated the food as to have kept them in a healthy progressive state, he has now to make all his preparations with a wise foresight only to be gained by experience. The place to lamb in is to be selected, and the time attended to. Further, the requisite assistance, and no more, has to be rendered at the proper instant of lambing, and the lamb and the mother both assiduously watched for days afterwards. Milk has to be given to lambs when mothers are unkind or destitute of milk ; sickness of various kinds has to be watchfully dealt with, and great judgment is required in the breaking of pains and mothering of ewes. Beyond this the operation of castration has to be performed at the proper state of the animal's strength, in the proper state of the weather. Attention to these duties rests almost entirely, and in many cases entirely so, with the shepherd. Supposing then that by performing his part in a skilful manner night and day, until the lambing is not only entirely completed, but the lambs are beyond danger, he saves the lives of ten ewes worth 40s. each and of twenty lambs that would shortly be worth 20s. each—no extravagant supposition in a large standing flock of fifteen score ewes—it is clear that in so doing he will save the amount of his wages.

It is found that skill is better worth having, in a shepherd, even though, as is commonly the case, it is combined with indolence, than the most conscientious and untiring exertion without skill. Under the latter the condition of ewes not unfrequently becomes too high, and inflammation induced, or undue anxiety to help in time of labour, increases the danger to the ewe, and the loss to the master. Mr. Stephens acutely remarks—"Evils will be *prevented* by skilful attention, and *cured* by attentive skill."

The man whose duty it is to shepherd a flock of Leicester sheep or a flock nearly crossed with Leicesters, will have more work than he who tends a flock of Downs or Cheviots, simply because the ewes from more frequently lambing pairs, or producing square-built, big lambs, require more assistance than the sheep of the

hill country. However well he has contrived to bring the flock within easy range, his eye and hand are constantly in action, and the master will do well to render him frequent assistance. At night, during a busy time, an extra pair of hands may save many lambs.

Every breeding farm should have a paddock consisting of two or three acres, well protected with a high hedge, and situated near the shepherd's or the farm-house. In lieu of such a permanent lambing fold, a row of faggots, obliquely laid upon the sward, and staked down, or a line of hurdles, wattled with straw, cutting off a bit of the most convenient grass-field, can be made to answer the purpose. Indeed the stack-yard is often used, and with less expense. Set up within the enclosure, in some warm situation against a wall or hedge, roofed with straw, a row of pens, constructed of wattled hurdles or stubble. They serve as a refuge for ewes that lamb in the night, or at any other time of day, and require temporary protection from cold, wind, and rain. If possible the pastures into which the lambed ewes are turned are provided with triangular shelters, or pens made of three wattled hurdles.

The fold is intended to hold either the whole flock, or those who by their marks are expected to lamb first, and they are driven in at night-fall.

Those ewes that have no lamb, termed generally "guile," must about this time be selected and put with the fattening sheep. Their blooming fleece and active motions betray them; and if a doubt exists, the shepherd should examine the udder. If the teat upon pressure yields no dark, thick viscid substance, the fact of no lamb may be considered proved. Before the lambing commences the shepherd must be supplied with brandy, castor oil, Epsom salts, ginger, peppermint, spirits of nitre, laudanum, one or two bottles for milk, a cord, knife and hook; with the most important of these he must fill his *budget*, and the rest must be at hand. For his nightly rounds he will need a lantern, and to facilitate the capture of individuals of his flock without running any, a *crook* is necessary.

Symptoms of Labour.—These are enlargement, and reddening of the parts beneath the tail, drooping of the flanks, impatient stamping, isolation, frequent stretching, shifting from place to place, lying down and rising almost immediately.

Labour and its Phases.—The immediate preliminary of labour is the expulsion of the bag of water from the vagina, subsequent to which ensue violent pains, and seeming desire of relief. But until the yellow hoofs appear in the passage, with the mouth lying upon them, the ewe should be left entirely to itself.

In case the ewe proves too weak to deliver herself, the shepherd must deliver her, with the remembrance that a hasty parturition superinduces inflammation. Experience must guide him as to the proper time to wait between the appearance mentioned and the assistance rendered.

Where the shepherd is alone, the most sensible mode of delivering a ewe is by gently laying her on her left side. He then bestrides her body, kneeling, with his right knee against her loin, his left heel against the lower part of her abdomen, and, of course, his face to the tail. Thus with both hands free, he proceeds to push out from him, with both hands, one leg of the lamb, and then the other, and seizing both legs above the fetlocks with his left hand, he pushes them downwards from the ewe's back. With his right hand he endeavours to free the head of the lamb from the vulva of the ewe; which done, the action of the hands being simultaneous with the strainings of the ewe, only *helping* not *tearing*, the operation is completed. Pains are taken to induce the ewe to recognize the lamb; it is placed near her head, its tail is put in her mouth, and if she attempts to run away, as many will do from their first lamb, she is penned with her lamb, and if necessary penned in very close quarters, so as to prevent her butting it.

If the ewe continues to lie and strain after the delivery, it may be supposed that she possesses a second lamb, which may be delivered in the same fashion. It not unfrequently occurs, however, that one of these two lambs is dead, or misplaced. In case it is dead, and has been so for a fortnight, it will be sufficiently rotted to allow of being pulled away peacemeal. If it is not so far decomposed, it must be cut away. When a false presentation does occur, the shepherd must gently endeavour to rectify it, by introducing his hand, well lubricated with fresh lard. And the less dogging and disturbance of any kind the ewes receive during pregnancy, the less risk is there of unnatural presentations. In case of twins there is danger of mistaking the legs.

Supposing the head to be bent back, it must be brought forward; and the legs, if bent, must be pushed back and straightened. The presentation of a *breech* gives rise to a difficult case, and renders the delivery tedious and painful. The hind legs must first be brought out, and the rest of the body must quickly follow, or the lamb will be drowned in the liquor amni.

Or it may be necessary to rest the ewe on her shoulder, raise her rump, and turn the lamb with the hand in the womb, to its proper position.

There are many curious operations rendered necessary by the delivery of malformations; but it is not necessary to dwell upon them here. Before I pass on, however, I will remind you that in case of twins the ewe may be so employed with and fond of the first-born, as to cause the pains of labour to cease for the second. The unskilful shepherd may be misled by this fact, and keen observation alone detects her true state.

To reproduce pains in such a case, or where fruitless pains have been succeeded by apathy, two table spoonsful of ergot of rye, repeated as a second dose in a quarter of an hour, will be efficient.

From the after-pains or reaction of the womb after birth, great loss is often sustained. This malady manifests itself sometimes immediately after parturition, or not until the first, second, or third day. It seems to be the effect of the great exhaustion of the nervous system. If it continues twelve hours, the life of the ewe may be given up. In severe cases a dose of two ounces of *laudanum* may be given three times a day. Inflammation of the womb after lambing is usually seen between the first and fourth day. Its course is very rapid and fatal. Bleedings, and purgatives of Epsom salts, are the usual remedies. The true preventive is care not to overfeed previous to lambing.

A little trouble is likely to be occasioned to the shepherd by a protrusion of the uterus in some of the ewes. A stitch or two with a needle-and-thread to keep it in, and a little laudanum to prevent paining, will generally suffice; but the ewe should never again be used for breeding purposes.

It may be as well to mention here that the placenta drops soon after delivery. It should on no account be allowed to lie upon the lambing-ground. Indeed, the pens and paddock cannot be kept too clean, or too frequently bedded, as many losses occur to the slovenly manager from the contact of rotting and impure substances, at this time, with the inflamed and lacerated parts of the ewes.

Suckling, &c.—It is well for ewes producing twins to be separated; for if, left in the crowd, they lose sight of one lamb, they often refuse to recognize it again, even if the separation has not existed three hours. There are endless repudiations and capricious partialities now shown by the ewes, which try the patience of the shep-

herd. But, as a rule, the maternal affections seem to be much dependent upon the flow of milk; and the shepherd, seeing that the well-filled udder is his best friend, never ceases to tease the farmer into large grants of cake and corn for the sucklers. Care should have been previously taken to divest the region of the udder of all wool; for its presence in the stomach of the lamb is a certain cause of death. Having exercised even great care in this particular, I have lost many lambs. The symptoms are, violent working in the body, with frothing at the mouth.

The first aim of the shepherd is to ensure for every lamb, as soon as possible after birth, a good drink of warm milk: this once accomplished, he rapidly increases in strength and ability to bear cold weather.

In the case of shearling ewes, who usually have a scant supply of milk, cows' milk is resorted to. New milk is supplied to them by means of bottles fitted with a mouth-piece, through which the lambs suck; or there are other modes of administering the lacteal stream of life: but the chemical constituents of cows' milk and ewes' milk, meeting in the stomachs of lambs, certainly do not agree well. Particularly they do not where the cow from which the milk is obtained has calved recently. Ewe-milk is poor in butter, but rich in curd; which is known to be the character of that of cows calved six months, and not again pregnant.

Should a ewe show indisposition to allow her lamb to suck, her udder should be examined. If it is hot and hard, exhibiting tumorization, fomentations, with the internal administration of Epsom salts, will be useful, followed by the vigorous thumps of the lamb, dispersing the tumour and promoting the flow of milk. Camphor and spirits of wine and Castile soap are a stronger remedy.

There is another troublesome piece of business for the shepherd at this time—I mean the *Mothering of Lambs*. This has to be done when a ewe dies, leaving lambs; when the lambs die, leaving a good flow of milk behind them, for the benefit of the wee things that are left destitute; or when a fine ewe, with abundance of milk, has but a single lamb, while a poor or young ewe has twins; the shepherd seeing it best to break the poor ewe's couple, giving twins to her that has the best supply for them. If this is done when the lambs are wet, there is no trouble involved; but the effort to induce a ewe to recognize a lamb that has been dropped some days, is very trying to the patience. Various methods are adopted to cheat the mothers, the shepherd rubbing the body of the lamb to be received with the body of the dead lamb, or (if in the case supposed last) with the body of the live lamb. If this will not do, the dead lamb is skinned; and the stranger, invested in its tegument, deceitfully obtains, like another Esau, its parental blessing. Close confinement is usually necessary to render these arts effective.

Those lambs unsuccessful in this line of deception, or, may-be, supernumeraries, depend upon the kind attentions of the shepherd or the dairymaid.

Before I pass from this portion of the subject, I must remember to say that, if the shepherd's house is not near, he should have access to some outhouse or moveable shepherd's house, with a fire, before which, wrapped in flannel, he may put such lambs as require this attention, as many do, during those cold stormy nights when lambs usually arrive in greatest abundance.

I must also remark that, should a case of puerperal fever occur, the shepherd must avoid touching the ewe so affected. If he has done so, some other person must take his accoucheur-duties for a few days, as the malady may be communicated to numbers of the flock by the shepherd's hand. Same one else, too, must do all the skinning, &c., during the lambing time.

Castration and Docking.—Ten days to a month after birth, all lambs not reserved for tups are to be castrated. The parts have not at this age attained too much rigidity, nor is the lamb so fat as to render fever imminent from the operation.

Authority says "it is best done early in the morning, in a fresh breeze, and by no means should the lambs be over-driven and heated previously." The *modus operandi* is as follows: The captured lambs are one by one placed with their backs upon the right shoulder of a stout lad, who doubling the corresponding fore and hind legs together in either hand, holds them steady in that position for the shepherd, who simply forces up the testicle with his finger and thumb, slits the purse, seizes the testicle between his teeth, and draws it out till the spermatic cord is broken, and so on. There are other plans, but none so simple as these. When the parts get too rigid to allow of the operation being performed with safety, silk thread is tied very tightly round the testicle, and circulation being cut off, they drop off in process of time. This seems a less barbarous, but more troublesome mode than the former.

The opportunity is now taken to dock the tail, dividing against the third joint. The object of this operation is to keep the sheep clean behind, which cannot be done when they wear long tails.

The lambs, after castration and docking, should not be placed in hign lank grass, or on stubble, where the parts can be irritated. Having surmounted these difficulties and risks, the shepherd may now begin to calculate his successes. Stephens says, "He should not be satisfied with his exertions unless he has preserved one-half the number of ewes with twin lambs; nor should he congratulate himself if he has lost a single ewe in lambing." "In regard," says the same writer, "to the yield of lambs of the Cheviot breed, it is considered a favourable result to rear a lamb to each ewe; with Southdowns a little more; with *black-faced* ewes 18 lambs out of the score of ewes is perhaps as favourable. Cheviots yield a few pairs, Southdowns more, black-faced ewes very few, while half the number of Leicester ewes should have twin lambs."

After-management.—So soon as the lambs are fairly a-foot, their dams are turned with them into the most forward piece of seeds, or to rape, rye, winter oats, or water meadow; the great point being to have abundance of succulent green food for the ewes as soon as they lamb. The ewes bite very closely, and eat constantly while lambs are with them, so that they shortly trim-off the grass or seed in a season unfavourable to vegetation. This fact renders the farmer much uneasiness; for when the pasture looks brown, he knows that he must either remove the flock, or, by keeping it where it is, impoverish the lambs, and so bite into the heart of the grass or seed, that the summer will pass before it recovers from the treatment.

The addition of a water-meadow to a farm is most valuable at this season, for these will always have a supply of food when other pastures are bare. Matters should so be arranged that there should be a succession of fields for the ewes and lambs, passing them on from one to another, and so resting each piece alternately, which will be found a more effectual method than that of stocking all lightly, but continuously. In removing lambs from a short to a full bite, caution is needed. It should be accomplished, old hands say in dry weather in the afternoon: else we have a flush of that quality of milk which produces *green-skit* in lambs. The premonitory symptoms of this malady are, general dulness, watery eyes, and stiff joints; half-an ounce Epsom salts with half a drachm of ginger is the best aperient remedy, to which may be added a table-spoonful of cordial, consisting of equal parts of brandy and

sweet spirits of nitre. When the action of the stomach shall have been stopped by the curding or coagulation of milk, an alkali should be employed to dissolve the coagulum. The best to be so used is magnesia. Painful heaving of the body indicates the cause of disease. With respect to *costiveness*, half ounce doses of Epsom salts repeated every six hours until relief is afforded, and removal to a more succulent pasture, are the proper remedies. Epsom salts will, too, generally relieve *fever* in lambs at its commencement. This malady is indicated by quick breathing.

Medicine can only be resorted to in individual cases. Where a malady prevails throughout a flock, it is best generally to meet it by judicious dieting.

The ewes must be kept in a thriving condition, that is, progressing all summer, and on the 20th of July or thereabouts, the lambs should be removed to a good clover eddish, at a sufficient distance from their mothers to prevent the one lot hearing the bleating of the other. I say that the lambs should be removed; but it will be better to say that the ewes should be removed, leaving the lambs where they were, for a day or two before the change is made. So that if they are to go upon clover eddish, it would be well for ewes and lambs to go there together for a day or two before the separation takes place. Experience will show that too much attention cannot be paid to such apparently trifling matters. It is in assiduous attention to such trifling circumstances that a farmer's profit consists.

I must not forget to state that when the ewes are shorn, the lambs should be dipped in a composition of arsenic: easily pre pared by boiling soft-soap, arsenic, and sulphur together.

This is done that the "ticks" they possess may be killed; for being the only harbours for them now their mothers have lost their wool, the lambs would be so irritated as to render all improvement impossible.

In conclusion, to be really successful as a breeder of sheep, the farmer must not be satisfied with a knowledge of his flock in the aggregate, but he must be intimate with the members of that flock individually, and their antecedents. This can only be obtained by going down thoroughly and personally into the practical details, as very few breeders care to do. None know the trouble, care, pleasure, and profit of such a course, but such as practise it. Not a day should go by, without the farmer passing in review every sheep beneath his eye; and at least once a fortnight they should all come beneath his hand, as the touch is the best test of condition and comparative improvement that can be employed. Such constant attention will give a power of discernment to be obtained in no other way; and it is the possession of this power alone which constitutes the profit of the flock; for the unobservant and careless master will only discover a malady when it has gone too far to be remedied, while the observant master will detect by a species of anticipation, and *prevent* rather than attempt to *cure*. To this homily I will append a remark made by that indefatigable general, the late Sir Charles Napier, when at Cephalonia, and leave my readers to draw their own deductions therefrom:—"How entirely all things depend on the mode of executing them! How ridiculous mere theories are! My successor thought, as half the world always thinks, that a man in command has only to order, and obedience will follow. Hence they are baffled not from want of talent, but from inactivity; vainly thinking that while they spare themselves, everyone under them will work like horses." EUMÆUS.

WINTER FOOD FOR CATTLE.

SIR,—The importance of winter food for either horses, neat cattle, or sheep, is so generally acknowledged, that there can be no need for any apology in offering a few hints as to the likeliest methods of getting up a supply. The turnip, the carrot, and the beet, formerly garden stuff, have all been long ago pressed into the service of agriculture: even the tender exotics have been forcibly taken possession of, and the cucumber family itself has been taxed to feed the cows, in the shape of gourds, &c. After such examples as these, let no one be surprised at any botanical extravagance that may hereafter be perpetrated.

The gourd, beet, carrot, and turnip require delicate handling and a fine tilth, besides skill and capital, and necessarily imply a considerable advance in shelter, drainage, levelling, &c; but there are situations of mountain, moor, morass, crag, cliff, &c., where cultivation of the above-named herbaceous plants is entirely out of the question; and as there are some thousands of acres of waste that receive rain and sunshine in England, and yet produce little return, it is time to try if these unprofitable servants could not be set to work. Most farms have some waste lands, and the following experiments might be tried on a small scale on these smaller wastes first, before attempting them on a larger scale. To propose anything tender as a tenant of the waste would be quite out of the question, therefore I shall proceed at once to lay before the readers of the *Mark-Lane Express* my reasons for suggesting the adoption of shrubs instead of herbaceous plants into the agricultural service.

There is a limit set by Nature to the culture of hardy plants, viz., the line of perpetual snow; and if we wish to know what tenants would suit our waste lands, bleak and dreary as they may be, we should consult the plants that have skirted the line of perpetual snow, and we shall find them ready to volunteer into a better country, and as we have no place so bad as the place they have left, it will be seen that they are decidedly bettering their condition, and thus all danger of growing them is at an end. I need not enumerate the plants that do not concern the farmer, for the lichens and other cryptogamous plants are not to be cultivated by any ordinary tillage, but the birch and the willow have their representatives in the high hill-tops bordering the boundary line where all vegetable life is wanting; it is to families like these, then, that we must look for the support we so much want of winter fodder. The tops of the heather may give a bite of green food for the "*hill wether*" to keep in life till the return of spring, but the plant is not adapted for a better place, and its rate of growth will for ever fix it to the mountain. It is far otherwise with the willow family. "*Growing like a willow*" is an idiom of our language; and when we see shoots of this tree (for it has both shrubs and trees) six feet long in one season, we cannot fail to appreciate the willow as a valuable fodder plant as far as bulk is concerned.

Some years ago I bought a goat and a kid, to try how many species of trees produced leaves and twigs that the goat would eat. Suffice it to state, here, that she ate the willow greedily; and when I was showing the experiment to an English nobleman who had travelled a great deal in the North of Europe, he told me that he had seen hay made of willow, and that it made good winter food. The willow has a great spread of foliage, and the amount of cellular tissue in the leaves and bark bears a

very large per-centage indeed to the woody fibre of the green shoot. All immature leaves, by a law of nature, adhere firmly to their shoots: when the leaf is ripe, it cuts itself off, with a clean-healed wound, in a very workmanlike manner; therefore in making hay of shrubs the leaves must be decidedly unripe in order to adhere to the stems. I need not tell any one that the willow will grow in any mud-bank at the level of the sea, and I have already said that the Salix antarctica on the mountain is a creeping shrub on the verge of perpetual snow. This immense range, from undrained swamps to bleak hill-tops, speaks volumes for the economical use of the willow; and if any one were to introduce a plant half as useful as the willow, to our agricultural societies, from some foreign country, he would be considered a benefactor to agriculture. When goats and rabbits bark trees for food in winter, they teach us an excellent practical lesson—viz., that the bark, and even the wood itself, is not so bad an article of food as we might have thought it to be; and when we see a person able to convert the woody fibre of an old shirt, or even a heap of sawdust, into sugar, we find that it is not without reason that the hares and rabbits have a nibble at the apple-trees in winter: but I should despair, after all this, of doing any good with such a subject, were it not that I have already one link in the chain, to weld this idea into—namely, the gorse, which seems now fairly adopted into agriculture. Yes, it is a fact that horses have actually been eating sticks, and thriving well on them. Thirty years ago, I saw the whin-mill at work, reducing the prickly fodder of the gorse-plant into food for horses; and all evidence, then and since, goes to prove its vast importance, not only as a tenant of the waste, but even as a cultivated plant for fodder.

After a very long acquaintance indeed with the plants indigenous to our clime that are likely to prove of service to us in cultivating what may properly be termed our wastes, I find only three that seem perfectly at home as slaves, or drudges, to do this dirty work; and they are —first, the willow, that is willing to grow in our osier-beds, in that which has not even the name of "dry land:" it will also thrive well anywhere else, for it is propagated by cuttings merely stuck into the ground; and if there be only one joint in the ground and one above it, the tree is planted. Willows are used by planters as nurses for other trees; and M'Gregor found the black sallow particularly excelling as a screen against the sea-breeze. My father showed me large willow-trees, that were once the twigs used for tying up the bundles of trees from the nursery; and when he had planted the trees, he cut these twigs into sets, and stuck them into the ground: therefore, what I have stated about the willow is no experiment now, but an established piece of practical planting. Next in order comes the gorse, as a plant for waste lands; but of this I mean to say nothing, and pass on to the third slave or drudge, which is the ivy. This plant is one of our most beautiful evergreens, and is well known to gardeners and planters as a very bad character. It is so uncharitable as a neighbour to other shrubs and trees, that it beggars the earth in which they grow by its roots, and fixes the bark of even large trees so tightly to their stems, that the trees are actually choked by the network of ivy-shoots. All this merely illustrates the fact of this important plant being out of place. I have seen the same plant covering the grey face of a huge rock, and have seen the birds flocking to it for shelter; and in winter, when scarcely anything else was to be seen for snow, I have seen the shepherd cutting his ivy, and the anxious flock waiting around him for its downfal. The range of this plant, therefore, in no way interferes with that of the willow or the gorse; for it has a region of its own. It is a most determined grower. Wherever it can find a little vegetable mould, it will stick on like a leech, and never misses an opportunity of raising itself on any prop that comes in its way. It grows freely from cuttings, and still more freely from its berries, which, in good localities, it bears plentifully. It has no prickles, like the gorse, to contend with in its cultivation; and it forms a scene of singular beauty wherever it is cultivated. As a cover for game, it is a plant of the highest importance, and should never be planted where it has to be rooted out, as it is very unwilling to be dislodged when once in possession.

The limits of a newspaper will only admit of a hasty glance at these matters; but, as they will fall into hands that only require reminding, and to whom the things spoken of are no strangers, I must let them pass without further comment.

I remain, Sir, yours respectfully,

ALEX. FORSYTH.

100, *Quay-street, Manchester, Feb.* 24.

A SUCCESSFUL METHOD OF RAISING DUCKS.

Believing it to be the duty of every individual to contribute, for the benefit of society, any information he may possess, however small, and on subjects ever so humble, and having for several years past been in the habit of seeking recreation during those hours which were not devoted to severer studies and labours, in a variety of experiments on subjects of Natural History, I propose giving you the result of some experiments in raising ducks, were carried on during a number of years, and which finally eventuated in complete success. It is sometimes beneficial to examine the causes of our failures, and it affords me pleasure at this moment in retracing the steps by which, after many disappointments, I gradually accomplished the objects to which my inquiries and experiments were directed. As an account of the process by which I arrived at these successful results may not be uninteresting to those of your readers who devote themselves to rural pursuits, and who pride themselves on having a well-attached poultry-yard, I hope it may be no tax upon their time and patience if I go somewhat into detail.

During many years I was struck with the general want of success which attend the raising of this species of poultry. Not one-sixth of the young were ever raised; they appeared to be subject to innumerable diseases. Those that escaped were stunted in their growth, and did not arrive at full size till they were many months old. The general complaint among farmers and planters was, that this, the most valuable of our poultry, was a puny bird, hard to raise, and subject to many diseases. They could raise fowls and even turkeys, but there was no certainty with regard to the duck. Desirons of investigating the causes of a failure in

raising a bird which in its wild state is very hardy, which although exposed to all the vicissitudes of the weather, raises large broods of young, I procured several ducks, determined to pursue my experiments in various ways till I should either be successful, or be satisfied that in a state of domestication there existed obstacles to their successful rearing which no foresight or care could prevent. At first I adopted the usual mode of giving them access to as great a body of water as I could provide for them in the yard. I therefore had an artificial pond made near their coops, to which they could resort as often as they chose: where they amused themselves at all hours of the day, in dabbling around the edges of the pool, and in swimming and diving in the water. But they did not grow; they were subject to cramps and fits; and one after another died, until I began to think that water was not their proper element. I varied their food; gave them rice flour, corn grist, boiled potatoes, hominy, bran, and many kinds of vegetable food, but with the same results; and of a hundred young that were hatched, I scarcely raised a dozen. I then began to mix with their food various medicinal herbs, believing that this might correct some deleterious properties of their food; but it was to no avail. I next procured the different varieties of ducks for breed, thinking that perhaps one kind might be better suited to the climate and to the confinement of the poultry-yard than another; but I was soon convinced that my want of success was not owing to my breed of ducks. Several years passed away, and left me pretty much where I began, and I was almost ready to abandon any further attempts at raising the ducks.

The thought at last occurred to me that in the food with which we usually fed this species of poultry we departed widely from nature, and that although the old ducks in their wild state fed on rice and the seeds of various grasses that are found along the edges of the rivers, brooks and ponds, yet that at the spring of the year, when the young wild ducks are hatched, there are few seeds ripe; and it is questionable whether at that early age they feed at all upon grain or seeds. There appears in the digestive organs of these young birds something unsuited to this kind of food; it passes through them without affording much nourishment. I had ascertained by dissection that their gizzards were filled not with vegetable food, but with the fragments of small craw-fish, worms, and various aquatic insects, as well as the spawn of fishes; and I determined in the following year to try the effects of animal food. In due time my young ducks were hatched; beef was given them at first, after having been chopped very fine; this they devoured greedily, and ate it in preference to all kinds of vegetable food. The effect upon their health and growth was immediate and surprising. They appeared to grow faster than any other poultry; in a few weeks they were out of danger, and in a few months fit for the table. As beef was expensive, I tried cheaper kinds of foods, such as the haslets of animals, crabs, fishes, &c. The result was equally favourable. I was now satisfied that in the article of food the end is attained by simply following Nature and giving the young ducks animal food.

But although my experiment was thus far favourable, I found that many of my young ducks died after having been suffered to go in the dews and water; and that after many showers of rain they became thoroughly wet, and that when showers were succeeded by hot suns they were subject to a disease of some apoplectic character, or a *coup de soleil*, which killed numbers. Here I was much puzzled. I had succeeded in one instance by following Nature; but I found that I could not carry my theory through, and that water affected the domesticated duck very differently from what it did the same bird in its wild state. The fact was not unknown to me that the down of young wild ducks is almost impervious to water; they are exposed to dews and rains, they dive to the bottom of pools and streams, and live in the water; yet they always keep dry. An oleaginous substance is spread over their feathers, from which the water glides off instantaneously, and leaves the birds dry during all weathers. Not so with the young of the domesticated duck. Owing either to the confinement of numbers in a small space, where their down becomes ruffled and displaced, or to their not being able to procure that kind of food which in the wild state is favorable to the secretion of that peculiar oil which is found contained in the glands of birds, and which serves to lubricate their feathers and protect them from the wet, the down of the young tame ducks soon becomes thoroughly wet; and when this is once the case, it is subject to various diseases, and is difficult to raise. To accommodate the young duck to that artificial state into which it has been thrown by domestication, I found it necessary to adopt some mode by which during the first few weeks of its life (the only time in which it requires much care) it might be preserved from the effects of that element which in its native state is almost its only residence and furnishes its subsistence.

A little reflection enabled me to guard against the inconveniences and dangers which result from this state of domestication. I had my coops built pretty large and tightly shingled, so as to be impervious to water. The young ducks were not let out in the morning dews till the sun had dried the grass; and the vessels in which their water was placed were railed over so that they could drink by inserting their bills between those little railings, but were prevented from getting into the water. After following these simple directions with regard to their food and shelter, I found that, by a little attention of a servant, I could supply my table with ducks the whole year round, that I seldom lost one in twenty, and that they were free from all diseases. I raised from 100 to 300 ducks per year, and now found that they were the easiest of all poultry to raise. I communicated the result of my experiments to my friends. Those of them who had the disposition, the patience, and industry, followed my directions, and in every instance met with the same success. I have their assurance that they can raise ducks in any numbers, and some of them have for the last two or three years supplied our markets with from three to five hundred ducks of the largest size and fienst flavour.

After having carried my readers through this,

perhaps to them, tedious detail of experiments, which cost me much time and attention, but for which I was more than repaid by the successful result, I shall now proceed to give, under different heads, such simple directions as will enable our planters and farmers to supply their tables with this kind of poultry, which might be an object to those who are in the habit of supplying markets.

1st. *The Species and Varieties of Ducks best adapted to the purpose of Breeding.*—The only two species of ducks that are raised in the United States are what are commonly called the English Duck and the Muscovy Duck. The English Duck is a descendant of the wild duck that visits us every winter in such numbers, called Mallard (*Anas Boschas*); is found also in Europe, and breeds in England. Although not the largest, it is certainly among the finest-flavoured ducks in the world. The flavour of the famous Canvass-Back Duck (*Anas Vallisneria*) that is found so numerous in the Chesapeake, and more recently in the Santee and at the mouth of the Savannah River, is no doubt, superior to it, but it is supposed that this is owing to the peculiar kind of root on which that bird feeds, believed to be the *Vallisneria Americana*, and that were it fed on common food its flavour would not be superior. The English Duck, which is so common in our yards, has, from its long domestication, run into a number of varieties which differ so much from each other as to appear like different species; they are of different sizes, of a variety of colours and some are tufted. The variety to which I have usually given the preference, goes by the common name of Madagascar Duck; is distinguished by its being of the largest size, having a pretty long neck, and almost invariably a light streak above the eyes, and usually a small streak extending from the lower part of the upper mandible to below the eye. The Muscovy Duck (*Anas Moschata*) is another duck more recently introduced, but which is now very common, and is well deserving a place in our poultry-yards. It was formerly, by most writers, considered as coming from the Eastern Continent; but is now well ascertained to be a native of South America. This duck, in our southern climate, is, perhaps, more hardy than the other: sets more steady on its eggs, and lays in the spring and fall. A mongrel breed between this species and the English duck is easily produced, and has become common; but these, though they are good layers, are unable to propagate their species. There are other species of ducks, which the curious in these matters have partially succeeded in domesticating. I once saw a fine flock of the Gadwall Duck (*Anas Stropera*) which an individual in the upper part of the State of New York had succeeded in raising from ducks which he had captured, and which bred freely in his yard, and made no attempts at flying away. Our beautiful summer duck (*Anas Sponsa*) breeds freely in some parts of France and in the Zoological Garden, in England. But it is very probable that the two species above mentioned are as well adapted to our purposes as any other, and that for many years they will be the only ones which will be generally kept in our poultry-yards. One drake will answer for five or six ducks; where mongrels are to be bred, place in separate yards one Muscovy drake to four English ducks.

2nd. *The best mode of procuring an abundance of Eggs.*—When ducks are raised in the country and have access to rice-fields, ditches, ponds, and the borders of rivers, they find food best suited to them, and generally lay early and freely; but where they are necessarily kept in yards, and do not possess the above advantages, it will be necessary to adapt their food to their situation. A mixture of any kind of animal food with their rice-flour, corn meal, or grist, given them regularly and plentifully three times a day, will enable you to procure a great abundance of eggs; where this is neglected your English ducks will lay but sparingly. I have observed that animal food is not so necessary to the Muscovy duck, but that they generally lay freely on being fed on grain alone.

3rd. *Sitting and Hatching the Eggs.*—The English duck, although a good layer, is very careless about hatching its eggs until late in the season. I have invariably used the common hen for that purpose; and when the young ducks are removed, as soon as they are dry their foster parent will sit again on other eggs, and I have thus known a single fowl to bring out three and even four broods of young ducks in succession. In that case she should be repaid for her faithfulness by being richly fed. The young ducklings in this climate leave the shell on the twenty-sixth day; the Muscovy sits a few days longer. A fowl of tolerable size will cover from thirteen to fifteen eggs. After the eggs have been four or five days under the hen, you may in the evening examine the eggs by the light of a candle or lamp. Place the eggs longitudinally between the fore finger and thumb—if the egg is likely to hatch, it will be of a dark colour, with streaks of red frequently perceptible; and the cavity on the thick end will be somewhat enlarged and transparent. If it is a clear egg, it will be wholly transparent, and it ought to be removed at once; and if it has not been too long kept in the nest, it is still fit for use.

In this way, when several hens have been set nearly at the same time, it will frequently be practicable to remove a sufficient number of clear eggs, so as to place a fresh setting of eggs under one or more of them. The Muscovy duck sits faithfully, and may as well be permitted to hatch her own young.

4th. *Method of Destroying Fowl Lice.*—The insects which infest the sitting hens may be easily destroyed by thoroughly sprinkling the nest and wetting the fowl even to the skin with a strong decoction, made by pouring hot water on a good handful of common leaf-tobacco, mixed when cold with a table-spoonful of spirits of turpentine, and double the quantity of gunpowder. It will be well also occasionally to take away their old nest, and make a new one of fresh hay or straw.

5th. *Duck Coops, Food, and manner of Rearing the Young.*—Let your coop be made pretty large, say three or four feet in length and three in depth; let it be well shingled so as to exclude all water, and have a good pitch towards the front; let it be tight on three sides, and barred in front, with a

slide below the lower bar, so as to retain the ducks in unfavourable weather. A space of 10 or 12 feet square, formed of common boards set up edgewise, will, when you have not much room in your yard, suffice for fifty ducks. Keep making coops in proportion as your ducks increase in numbers, and endeavour to keep the different sizes separate. The first brood, early in the spring, requires for a few days the warmth of the hen's body; and she should not be made to take care of more than twenty or thirty. A little later in the season, the young that are then hatched do not require the services of their foster-mother, and may, from the beginning, be placed in a coop by themselves, to the number of fifty. Young Muscovy ducks may be treated in the same way, and they and the mongrels and English ducks may all be indiscriminately reared together. As soon as your young ducks are hatched, let them be placed together for a few hours in a basket containing some warm inside lining; and when they have sufficient strength, place them with the hen in the coops; feed them with meat or animal food of any kind, chopped fine with a common chopping knife; for convenience I have usually had it boiled; a little rice-flour or corn meal may be mixed with it, and the latter may be increased if you have but little meat. Let this be continued for three weeks, and they are out of danger, and can be raised on any kind of food. Still it is to be observed that ducks will, in all cases, thrive better on animal food; and where this can be conveniently obtained, it may as well be given them. Those planters who live near our seacoast, by running a tight board fence across any small branch of salt water, and placing in the centre a fish trap made of laths, can easily procure a sufficient quantity of fishes and crabs to feed all their young poultry. A man with a cast-net could in half an hour do the same. I have known persons in the interior of the country substitute squirrels, rabbits, and even venison; and one gentleman fed his young ducks on the flesh of alligators, thus rendering that which was a nuisance subservient to his profit. When your young ducks begin to be tolerable feathered on the sides, which will be in five or six weeks, they may then be turned into the common poultry-yard, always bearing in mind that those which are best fed and obtain most animal food thrive the fastest.

I have not treated of diseases to which ducks are subject, since by the above treatment I have generally found them healthy. As this is a long essay, and may be too great a tax on your readers to peruse, I would give in a single line the substance of my directions for the successful rearing of young ducks: *Give them animal food, and keep them dry.*—American "Southern Cultivator."

HOW GOOD AND BAD HARVESTS COME IN SUCCESSION.

A lecturer upon astronomy the other day astonished his audience by stating that the prices in Mark-lane were greatly influenced by spots distinguishable upon the face of the sun. These he went on to describe as continuing to increase in number for the space of upwards of five years together, until about three hundred became observable, when in like manner they would again decrease through another period of time, the temperature of the earth being diminished or increased in corresponding ratio. This is pretty much in accordance with the prevailing opinion that good and bad crops are produced in cycles, which have however been ascribed to embrace periods of seven years each, instead of five years' duration, as here stated. Whether it be one or the other, or neither, remains yet to be ascertained; and this can only be accomplished by comparing results extending over a number of years together. It is quite certain that some operating cause continues to produce several fine seasons in succession, and bad ones inversely. This effect will most probably be hereafter traced to electricity, which is acknowledged to be the active agent directly producing atmospheric phenomena.

Upon looking back to our journal we perceive that 1831 was the concluding year of a series of seven wet and cold seasons preceding; and 1832 the first of a series of years unprecedented for productiveness, which continued with but little variation until 1840 and 1841, both of which were wet seasons, while 1842 was remarkably warm and dry. And so likewise were 1846 and 1847: in the former year the potato murrain first appeared; the crop up to the 27th July had shown no symptoms of disease; but the temperature, which up to that time had been very high, suddenly fell, accompanied by heavy rain. 1849 and 1850 were wet and unproductive seasons, and 1855 variable, but mostly backward, until 1857, one of the most genial and dry seasons on record, and attended with great productiveness. Upon tracing still further back, we find the year 1816 associated with an extraordinary wet and late season and harvest; then 1817 fair; 1818 hot and unprecedentedly dry; 1819, 1820, and 1821, mostly cold and moist; 1822 fine, and an abundant crop. So far we have data; which, upon examining closely, we find that taking seven years previous to 1832 the seasons were wet, cold, and unproductive; from 1832 they were mostly dry, and all of them productive; antecedent and subsequent to these periods they were so variable that no continuous series can be traced sufficiently to corroborate the theory we are investigating. The winters most remarkable for severity are 1814, 1823-4, 1827, 1839-40, and the summers from 1824 to 1831 were exceedingly wet and cold, especially at the latter end of May and to the middle of June—all of them being unfruitful.

So far it appears that the productiveness of our green crops is mainly dependent upon the state of the weather from March until the middle of June, and more especially upon the temperature during the month of June, that is from the 1st to the 21st. A dry May is very conducive to the formation of a full-grown wheat-ear, and a dry and warm temperature in June for bringing it to perfection. Whenever the temperature of the weather is such as to bring it quickly forward at that

immediate period, with a fine and dry state of atmosphere, but little danger need be apprehended of a good yield. The subsequent weather throughout July being of the same character, an abundant crop may be calculated upon.

The injury sustained from insects is also almost superseded in such state of auspicious weather, as it has been found that the wheat-midge can effect but little mischief, and that mildew is not extensively produced in such seasons.

So far as we are enabled to trace effects, we find that the productiveness of our cereals is mainly dependent upon a warm and dry atmosphere; but that such a state of weather can be foretold or be calculated upon from the average of preceding years, we could hardly venture to say. There is, still, a prevailing notion of good and bad seasons following each other in cycles of years.

The temperature undoubtedly is little changed for several years in continuation, but not with such a degree of uniform regularity as to establish any rule therefrom. It has been observed that whenever the general temperature is lower than ordinary, such seasons are most generally rainy; and although we cannot trace the immediate cause of rain prevailing for long periods together, atmospheric phenomena are undergoing such investigations as will probably ensure an approximation to this. Certain known laws affecting the cause and amount of rainfall in various countries and districts have been already ascertained and established. Rain is found to decrease in quantity from the equator to the poles, and to increase in quantity from the coast to the interior of Europe, especially as we advance to the table-lands. But this law is reversed in ascending steep and rugged mountains. At Keswick, in Cumberland, it amounts to 67½ inches, while in Essex it is only 19½ inches. Also upon our western shores the quantity of rain is treble in quantity to that which is found to prevail upon our eastern coast. This arises from the westerly winds traversing the Atlantic, whilst the easterly winds come over large inland tracts of the continents of both Europe and Asia; consequently whenever strong easterly winds prevail in the spring months, the weather is generally cold but dry; but as dryness is suitable to cereals, they advance with far greater rapidity as soon as the weather becomes mild, with showers from the west. It frequently happens, however, that but little rain accompanies the westerly winds in the early portion of June; and whenever such is the case, the season is invariably auspicious and congenial to production.

FARM-SERVANTS AND FARM-HORSES—TWO RECENT CASES.

Few men achieve any great success in an occupation that they have not some pride and pleasure in pursuing. It is a feeling that with us all should be especially encouraged. From the day a lad joins a class at school, to the time he sets up for himself, there should never be wanting such an ambition to excel. It is not only our children, however, we should endeavour to imbue with this becoming spirit of emulation and improvement. There are others under our control, who may profit both them and ourselves, equally by this same inward prompting. A servant who does not pride himself on his work and his tools is seldom worth much. It is in suchwise, in fact, that you gather the best evidence of his character. The gardener shows his flowers and fruit. The butler plumes himself on the condition of his wine and the arrangement of his cellar. The cook sends up a soup that will not even submit to another pinch of salt; while neat-handed Phyllis' plate looks as well as if you kept forty servants instead of four. But, if there be one who, above all others, has a real gratification in doing well what he does at all, it is the horse-keeper. No matter whether it is the be-wigged and be-plushed coachman of "the great people," the hobby-de-hoy who look after his first four-wheeler, or the carter who brings his team to market—as a rule,

"No mothers or nurses
Take more care of their babes than they do of their horses."

It is rarely indeed that such a man forgets his charge. The groom at the covert side daintily wisps his horse over with his own silk handkerchief; the drayman's "filler" would seem to get more stout even than his driver; and the veriest man-of-all-work thinks of "the nag" long before he does of himself.

It is a pardonable and almost a national pride we have. But it may be carried too far; in instance of which we may briefly tell two histories that have been brought especially under our notice. They may act as something of a caution with the one class, and at the same time as something of a plea with the other. There farms, then, at Westdean, in Sussex, one Mr. Thomas Newman, who, until very recently, had in his employment two men of the name of Gabriel. The elder of these had been in this same service for so long a period as fifteen years, and never, according to his master's testimony, had he in that time robbed Mr. Newman "of a sixpence." This is something of a character at any rate. The other man, a son or brother most probably, does not appear to have been settled here so long; but we will assume that he did not disgrace his relative or his place. In an unhappy moment, however, these two men have sacrificed every thing. They stand as convicted thieves. The constables are sent for. They are taken to prison, and in due course before the Bench of Magistrates. The prosecutor would seem at last to have even pleaded for them—for the elder particularly, "who had been fifteen years in his service; never robbed him of sixpence; had a large family, and a wife very ill." The Chairman of the Bench himself admitted that "they had erred more from ignorance than any dishonest intention; they had not, it was clear, appropriated anything to their own advantage." Still the law must be enforced, and the two Gabriels are sentenced accordingly to three weeks' imprisonment each in the Petworth House of Correction.

And what have these unfortunates, who erred more from ignorance than intention, been doing? Stealing tail corn for their pigs? Or getting a few apples out of the orchard for their children? Or making love to Betty the maid, and getting beer and bacon for themselves? No. A man with fifteen years' character is scarcely as selfish or as culpable as this. The Gabriels had been robbing Mr. Newman of his oats—to feed his own horses with; or, as it is written in the local report of the case, "it came out that the men had taken the oats without their master's permission, to give to their horses."

No question they did wrong. No doubt Mr. Newman should not suffer from having his horses over-fed and his corn wasted. But, surely, justice in such a case might be tempered with mercy! "Not a sixpence" ere this had Mr. Newman lost by an old servant with a bond of fifteen years between them. It was clearly, then, a first offence. And was it worth while for a first offence, and such an offence too, to destroy this fifteen years' acquaintance, and drag off poor Gabriel from his family and ailing wife to Petworth gaol? "To be branded," a correspondent writes, "as thieves, and to associate, as I suppose, for three weeks with thieves, to the great injury of their own morals and future self-respect, the greatest safeguard against crime." "Did these poor men," we must quote him yet further, "imagine they were guilty of a worse act than a servant (with far more opportunities of self-improvement) would admit of, who had cut off a slice of meat from the joint for the cat? Or taken the dripping as her perquisite, not to minister to her master's good, but to buy finery for herself?"

We tell this story more as a caution to the farm-labourer than anything else. At the same time we are bound to confess that it sounds unusually harsh; and we believe that few farmers under the circumstances would have proceeded to such extremities. The result of such a course can only be irreparable injury to all concerned. It was but on Monday evening last that we heard a member of the Central Farmers' Club speak to the value of mangel wurzel as food for sheep and pigs. He had only found one difficulty associated with its use, and that was, the men would over-feed with it. Now, did Mr. Stagg ever dream of giving his shepherd or yard-man into custody for taking too many mangel? And, if not, why not? Did not the shepherd take mangel for precisely the same purpose the carter did oats? There is a nice line to draw here, but no wise man will draw it too finely.

The other case which arose from exactly the same cause, the man's pride in his horses, occurred on the farm of Mr. Ibbott Mason, at Somersham in Huntingdonshire. The ploughman here secretly administered drugs to his horses—antimony amongst other things—with the notion of making them look better, and which he had openly purchased of a chemist in the village for that purpose. Three good horses died from the effects of this. The veterinary surgeon declared on examination they had been poisoned. The mixture was found in his stable. And, indeed, the man at once admitted what he had done. The injury in this instance was, of course, of a far more serious character; but the magistrates could see no malice in the case, and as the man had only erred from ignorance, he was acquitted. At Chichester the chairman went so far as to tell the Gabriels they too had erred from ignorance. The law, however, in this instance, took a different complexion, and they went to gaol for feeding horses, while Mr. Mason's man gets no punishment for poisoning them. We do not go so far as to say he should; the druggist certainly appears to be the more culpable of the two. What we do wish is that we should have had no occasion to make the comparison. A man who has absolutely lost so much valuable property as Mr. Mason did, must, as a moral duty, institute some public inquiry; but need we sacrifice an old servant for a sieve of corn? Surely a reprimand might for once at least have been sufficient?

The more general publication of these two cases may be useful to both master and man. We counsel the former to let his labourers have the opportunity of seeing them.

THE FARM-HORSES.

In order to include the fullest and most comprehensive view of this subject, I shall first consider the extent of the arable portion of the farm best adapted for economising the labour of the farm horses; as, however desirable and beneficial it is to combine grass and arable lands together in laying-out a farm, yet, so far as the farm horses are concerned, it is only with the arable portion thereof we have now chiefly to do.

The results of great practical experience in most parts of the kingdom have demonstrated, that the efficient culture of about forty acres of loam, strong loam, loamy clay, or clay soils, will require the power of two good farm horses, such lands being kept under cultivation, and not subjected to the prescribed courses of husbandry usually adopted on light soils. On these soils, where the four-course or other shift is adopted, the same experience has demonstrated that a pair of active horses will suffice for the efficient working of at least sixty acres, because, as one-fourth, or more, is under a seed crop, there remain but forty-five acres, or thereabouts, for the pair to cultivate; and the land being lighter in quality, is worked with less labour proportionately, and will allow a sufficient margin for a little extra cartage of clover, hay, &c., from the seeded portion of the farm. It will also be found, from the results of the same practical experience, that the various kinds of farm-work, such as cartage in harvest-work or in manuring land, requiring a continuous succession of loads, or in any work requiring a relay of horses; or in seed-time, so that the harrowing and drilling go on simultaneously; or in turnip sowing, so that the manure is deposited and ploughed-in immediately—I repeat, it will be found that not a less number than six horses can, on by far the great majority of farms, keep up this continuous succession of general labour so as not to impede the regular farm-work; but with this number of horses, and the free use of one-horse carts, the various kinds of cartage may be economically performed: and, with good management, also all the other various kinds of farm-work may be carried on without let or hindrance. I hold it to be of great importance that this should be the case. The ploughman must not wait for the dung-cart, nor the stacker for the harvest-cart; but all must proceed regularly and in order together.

In accordance with this statement, it will therefore be seen that the farm should not contain a less quantity of arable land, of a strong texture or character, than 120 acres, or of light land not less than 180 acres, respectively; but the larger, in moderation, the more economically can it be managed.

To conduct the farm, then, most profitably, because most economically, we require it to be of the extent, at least, named above; and to work it properly, we require six useful farm-horses. What kind shall we select? How shall we procure them? What course shall we pursue to keep up the number? It will be foreign to our purpose at this time to enter upon the distinctions and qualifications of the various breeds of farm horses; I shall merely take this general rule—to select powerful draught horses for the heavy-land farm, and light draught horses for the light-land farm; *i.e.*, the large Lincolnshire, Cleveland, or Clydesdale horses for

the heavy land; the Suffolk Punch, the Norfolk, and other lighter breeds of cart-horses, for the light lands: these will amply suffice. The usual course to be pursued, in making this selection, and procuring them, is to attend the most popular horse-fairs in their respective districts, and to pick up individual specimens as required. Another mode is, to attend the various farm sales within any reasonable distance, and purchase such as are suitable. In the latter case, many admirable animals may be found; indeed, it is almost the only way to obtain first-class mares for breeding purposes, as few farmers will sell their best brood mares at any price. To keep up our stock of farm horses, it will be right to include both horses and mares in our selection, and the proportion should be four horses to two mares; the latter to be chosen with a view to breeding. If more mares are taken on to the farm, it may occasionally put the occupier to inconvenience, as in the event of all of them producing foals in one season, the necessary rest they would require of course impeding the farm-work; hence two would be found to breed a sufficient number of young horses to keep up the farm stock or supply, and for the occasional sale of a cart colt—generally a valuable animal, and ever in demand. I name this as a general rule; but as we cannot expect to obtain just the farm we want, either in extent or proportions of arable or pasture lands, the number of horses required will vary accordingly; and the extra number should, I think, consist of a larger proportion of mares than horses, because if the mares are not at all times fully required in farm work, they may be profitably employed in breeding, and there are certain seasons when they may be much better engaged suckling their foals than in the work of the farm; moreover, in busy seasons, and when the farmer is hard pushed for help, a little light work in cartage or the like, so as not to over-work or over-heat them, will do them or their foals very little harm, but foals should not partake of feverish milk.

Another very important part of this subject is the age of the horses we would select. I think they should invariably be young, or from two to six years old, and care should be taken to ascertain that they are sound, and good workers. Occasionally older horses may be purchased; indeed as respects "brood-mares" it will be found desirable; and as I have before said, they are generally best obtained at farm sales; and in such case a good mare must not be missed because she is a year or two beyond our prescribed limit as to age. It is but seldom that really good and valuable cart-mares for breeding purposes are exposed for sale in the open market or fair. Every farmer has his pet mare. I would on this point also suggest that it is always desirable to have at least one horse on the farm qualified for riding or driving, or as an occasional plough-horse: this might constitute an extra horse for any emergency.

HORSE-TAMING.

The *Boston* (United States) *Journal* has the following article on Mr. Rarey's system of horse-taming:—"We saw Mr. Rarey in this city some two years since, and had a long and interesting conversation with him in regard to his peculiar mode of subduing wild and vicious horses. Mr. Rarey is a small and rather spare man, the only peculiarity about his person being a very keen blue eye. His method of managing a vicious animal entirely precluded the use of force or fear, and he represented that his power was obtained solely through certain herbs and drugs, first subduing the desire of the horse to injure him, and then by inspiring the beast with affection and confidence, he is enabled to do whatever he chooses with him. These herbs and drugs are perfectly harmless, and as Sir Richard Airey says, 'there is nothing in the treatment but what any horseman would approve of.' Mr. Rarey did not communicate his secret to us, but we have no doubt his treatment is substantially the same as that described in the following extract, which has been floating through the papers of this country for several years:—

"'The horse-castor is a wart, or excrescence, which grows on every horse's fore-legs, and generally on the hind-legs. It has a peculiar rank, musty smell, and is easily pulled off The ammoniacal effluvia of the horse seems peculiarly to concentrate in this part, and its very strong odour has a great attraction for all animals, especially canine, and the horse itself.

"'The oil of rhodium possesses peculiar properties. All animals seem to cherish a fondness for it, and it exercises a kind of subduing influence over them.

"'For the oil of cummin the horse has an instinctive passion—both are original natives of Arabia, and, when the horse scents the odour, he is instinctively drawn towards it.

"'The directions given for taming horses are as follows:

"'Procure some horse-castor, and grate it fine. Also get some oil of rhodium and oil of cummin, and keep the three separate in air-tight bottles.

"'Rub a little oil of cummin upon your hand, and approach the horse in the field, on the windward side, so that he can smell the cummin. The horse will let you come up to him then without any trouble. Immediately rub your hand gently on the horse's nose, getting a little of the oil on it. You can lead him anywhere. Give him a little of the castor on a piece of loaf sugar or potato.

"'Put eight drops of oil of rhodium into a lady's silver thimble. Take the thimble between the thumb and middle finger, stopping the mouth of the thimble to prevent the oil from running out whilst you open the mouth of the horse. As soon as you have opened the horse's mouth, tip the thimble over upon his tongue, and he is your servant. He will follow you like a pet dog. He is now your pupil and your friend. You can teach him anything, only be kind to him—be gentle. Love him, and he will love you. Feed him before you do yourself. Shelter him well, groom him yourself, keep him clean, and at night always give him a good bed, at least a foot deep.

"'In the winter season, don't let your horse stand out a long time in the cold without shelter or covering; for the horse is a native of a warm climate, and in many respects his constitution is as tender as a man's.

"'If you want to teach him to lie down, stand on his left side; have a couple of leather straps about six feet long; string up his left leg with one of them round his neck; strap the other end of it over his shoulders; hold it in your hand, and when you are ready, tell him to lie down, at the same time gently, firmly, and steadily pulling on the strap, touching him lightly on the knee with a switch. The horse will immediately lie down. Do this a few times, and you can make him lie down without the strap.'

"Mr. Rarey has subdued many vicious horses in different parts of the country, accounts of which have frequently been published. Among other cases was that of a horse in Washington, which could not be handled. Under Mr. Rarey's tuition, in an hour and a half he made the horse so gentle, that he rode it down the open street without a bridle, beating a drum while seated on his back."

AGRICULTURAL BUILDINGS.

SIR,—In preparing an article for the columns of your widely-circulated Journal, one feels considerable delicacy in generally advocating or condemning any particular system, as the exceedingly variable character of the soil and climate of Great Britain, as well as the general contour of the country, render necessary a great variety of customs and systems of husbandry. But there are certain standard axioms in agricultural economy, as well as in every other science, applicable to all circumstances, and to be observed under every variation of soil or climate. Who, for instance, would doubt the necessity and propriety of draining wet or retentive soils, wherever they might be situated? But who is so absurd as to advocate a system of either deep or shallow draining as being applicable to every description of soil? or who will doubt the propriety of a rotation of crops? Who so unwise as to advocate the same rotation as being suitable for every district? The places of the luxuriant wheat and mangold crops, upon the calcareous flinty soils, and beneath the dry climate of the East of England, are occupied by the verdant pastures, the bulky oat, and rich alimenting turnip crops of the loamy soils and humid climate of the West. It is from being impressed with such feelings as these, that I feel a nicety in taking up the question of Agricultural Buildings in your widely-circulated Journal; for, whilst I feel convinced that all will agree with me in saying that substantial, ample, and commodious premises are of paramount importance to agriculture, I am at the same time aware that, within the precincts of the circulation of your Journal, a diversity of opinions will be found as to the amount of accommodation requisite, and the best method of arrangement. The long and severe cold of a Scottish winter renders it imperatively necessary that more ample and comfortable accommodation be there provided for the stock, than may suffice in the more mild and hospitable climate of the South. If I were to assert that this important attribute to successful farming is overlooked by *all* landlords, or neglected in *every* part of the country, I should be making an unwarrantable assertion; but if I say that few landlords attach to it that importance which it demands, and that the great mass of agricultural buildings throughout the country are in an unsatisfactory condition, I feel that I am making no rash assertion or uncharitable remark.

It is not my intention, upon the present occasion, to enter into the minutiæ connected with the erection or arranging of farm-buildings; but merely to throw out a few promiscuous remarks bearing upon the subject generally, and to press the importance of a much greater attention being paid to Agricultural Buildings, than in many parts of the country they have hitherto received. Next to long leases (and the one is almost a certain concomitant of the other), there is nothing more calculated to aid in promoting good husbandry than ample farm buildings. It is very possible that bad farming may be found where such premises exist, but good and successful farming can never be carried on with scanty and dilapidated buildings. Where the necessary shelter and warmth for stock are wanting, much of that nutriment which should tend to improve the animal is spent in maintaining that necessary degree of warmth which a comfortable lodging should supply, and the inroads of disease and death become more frequent; and, with insufficient accommodation, much loss and inconvenience is sustained. Implements must remain unprotected from the weather, a due regard to manure is often prevented, and even a full development of the resources of the farm is often rendered utterly impossible, or when the arrangement is inconvenient, much loss of time and additional expense in labour is involved. It has been computed that to have the steading conveniently placed with regard to the land, will upon a farm of considerable extent increase its value from one to five shillings per acre, and that an ample and convenient arrangement of the buildings will diminish the amount of labour and loss, &c., upon a similar farm to the amount of from £50 to £100 per annum. Theory at once points to the centre of the farm as the best site for the steading; but here, as in many other instances, principles must often give way to circumstances, and proximity to a good road, an ample supply of water for general use, or its acquirement as a motive power, are considerations to which proper weight ought to be attached in selecting a site for a farm steading. When the buildings are placed at an extremity of the farm, the expense of labour must then be raised to a maximum, and much loss and inconvenience experienced; the farthest fields are generally neglected for want of manure and their due amount of cultivation, and to erect off-premises for the accommodation of distant fields is a very slight mitigation of the evil, if indeed any at all; it is only incurring additional expense in erecting and maintaining extra premises, and after all attended with many inconveniences. Misplaced farm buildings are very frequently to be met with in several of the eastern counties of England; and, although I am not at a loss to assign reasons for the neglect of this important point, still I see no real cause why more active and energetic measures should not be taken to remedy an evil so prejudicial to successful agriculture. One would have naturally supposed that in a level country, intersected by excellent roads, there could exist no pretext for misplacing farm-steadings, and that they would be found planted down with almost mathematical accuracy. Quite the reverse, however, is more frequently found to be the case; and I believe the origin, as well as the continued existence of the evil in the counties just mentioned, is to be traced to some or all of the following sources, viz.; small parishes, glebe lands, charitable bequests, copyhold tenure, commons, yearly tenancy, and an indifference on the part of landlords. It may be thought that some of these can in no way interfere with farm-buildings. I consider however that all, more or less, have had, and still do exert, a baneful influence, both with regard to the choice of a situation and the provision of commodious and ample arrangements. By the intersection and cutting in of glebe lands, some farms are so detached that it would be impossible to point out a central situation; and so much negotiation is required with the lord bishop, the rector, and attorney, that few are bold enough to encounter the troubles involved in an exchange of their lands. Commons, too, whether as common or divided, produce the same injurious effects; and where parishes are small, glebe lands, commons, and small patches are generally found more numerous. Lands belonging to charitable bequests also, being generally inalienable, have a like prejudicial tendency to mar the compactness of farms, and to preserve the boundaries of fields upon which they, in common with glebe lands, &c., abut in that crooked, irregular, and unworkable state, so fashionable in the days of our forefathers, and for whose wisdom in this

respect we are quite at a loss to account. The serious annoyance and interruptions to the managing and improving of landed property from copyholds, manifests itself in a variety of ways, well known to manyby dear-bought experience; but we look forward to almost an entire abrogation of this evil through the instrumentality of the Enfranchisement Act.

Then comes yearly tenancy exerting the same evil tendency upon the melioration of farm-buildings that it does upon every other agricultural improvement. Its uncertainty encourages a system of patching; it renders it necessary for the landlord to undertake the *onus* of keeping the premises in repair himself, so that there is a constant patching-up, always doing, yet never done. With some tenants a carelessness gradually steals on, whilst others will have temporary conveniences, if they should be at the first expense themselves, and for some part at least they look forward to being paid by valuation by the in-coming tenant; and to such an extent has this got in some instances, that it is difficult to know what part of the premises belong to the landlord, and what is claimed by the tenant. But in those parts of the country where long leases have been a long-established system, repairs are generally thrown upon the tenant, and this item, duly taken into consideration by him in offering for the farm; but of course he does not accept of the premises in that insufficient and dilapidated state which satisfies the yearly tenant. No; before making his bargain he thoroughly examines their condition, stipulates what he considers necessary to be done, gets everything put in good and substantial condition, agrees to maintain them so during his tenancy, and to leave them habitable and tenantable at the expiry of the lease, under a penalty for non-fulfilment. Thus new buildings are erected by the landlord, and kept in repair by the tenant, who, being always on the spot, and using them, is certainly, under a proper agreement, the most suitable party to be entrusted with this duty. Indifference on the part of landlords has also in many instances proved a great barrier to efficiency in Agricultural Buildings. It must, however, be gratifying to all interested in the prosperity of agriculture to observe the lively interest which the nobility and landlords of England are now evincing in the cause, and under their patronage I feel convinced that nothing requisite to promote her progress will be overlooked; landlords will no longer look upon money properly applied in erecting ample and substantial farm-buildings as being thrown away, nor consider it any economy to withhold from their tenants any accommodation requisite for the proper cultivation of their lands, nor request their tenants to erect at their own expense a temporary and beggarly-looking faggot-shed, which at the best can only afford half shelter to the starving kine. No: landlords are now awake to the fact, that, to carry out successful farming, warm, well-ventilated, and ample accommodation for the stock must be provided; that upon occupations of ordinary extent machinery must be fitted up, and steam or water-power applied to perform with economy and expedition the various operations to which it is applicable.

And, finally, let us not forget the condition of the labourer, setting out perhaps upon a journey of some two miles before reaching the scene of his labours, and after being heated to perspiration, or wetted by the drizzling rain, he sits down in a cold out-house, or under the shade of an aged tree, to partake of his cold and scanty fare; tired and weary with the labours of the day, he again sets out upon his homeward journey. This must produce its effects somewhere. A full day's work cannot be got; and premature old age must soon consign him to some union workhouse. But the remedy is obvious. Erect cottages, at least for the horsemen and stockmen, at some convenient distance from the steading, where the labourer will be at all times near to, and ready for, his work, and sit down to his meals with comfort by his own fireside. He will be free from the contaminating influences of a village population, and the corrupting effects of the alehouse.

Such, Mr. Editor, are a few of the ideas which have suggested themselves to me upon the subject of Agricultural Buildings. Some of the evils I have mentioned may be unknown in some parts of the country, but most of them will be found to exist more or less in almost every district. A proper description of skill has yet scarcely been brought to bear upon the subject. The "old estate carpenter," and the majority of farmers, have as yet little idea of arranging a farmery consistent with the requirements of modern machinery, and the principles of improved husbandry. In most parts of England they still adhere to the old system of erecting a great barn in the centre, with a few sheds and lean-toos huddled around; whereas the architect who, under the encouragement of some nobleman, has brought to bear his scientific skill upon this subject, has generally gone to such expense with useless and ornamental fancies, that a poor rate of interest can only be obtained for the outlay; and for this reason the man of calculation at once sets it aside as impractical. Nothing ornamental is required, but everything that tends to good arrangement and substantiality; and this being kept in view, an outlay on agricultural buildings becomes a profitable investment.* There can be no reason why the establishments in which are manufactured the staple commodities upon which the millions of Great Britain are fed should not be conducted and arranged in that same orderly and systematic style which characterizes the manufacture of the fabrics with which they are clothed. The subject well deserves attention. Agriculture, as the sinew and backbone of British industry, requires the removal of every impediment calculated to mar her progress; and, looking to the British legislature, she requests their interference, by affording every facility to the exchange of lands, and the straightening and adjusting of boundaries between adjoining proprietors, by rendering it compulsory upon the one on demand of the other, upon fair and equitable terms. The introduction of steam ploughing, and other modern implements, must ere long demand this alteration, for it is utterly inconsistent to suppose that the whims and crotchets originating, and perhaps necessary, during the dark ages of feudalism should still be allowed to exist, to impede the progress of enlightened civilization.

Yours, &c.,

WM. ARNOTT.

Melton, Woodbridge, 16th Feb., 1858.

THE GREAT OWNERS OF THE SOIL IN IRELAND.

SIR,—I have understood from the highest authority that Ireland, take it all in all, is the finest country for land under the sun, but it has been greatly neglected in the cultivation of it. Let the owners of the land in Ireland give the cultivators of it a tenant-right, *alias* justice, for money laid out in unexhausted improvements upon their farms, and then it would tempt a vast number of first class farmers from England and Scotland to cultivate well the ill-used Irish soil, and would soon cause the 4,000,000 acres of waste improvable land in Ireland to be brought into a high state of cultivation, which would be a fine example to all the world, there being in Ireland 2,330,000 acres of boga, all drainable, all improvable.

SAMUEL ARNSBY.

Mill Field, Peterborough, Feb. 24, 1858.

---

* The best models of agricultural buildings to which we can refer are to be found in Lincolnshire, and the more northern counties of England, and generally throughout the best agricultural districts in Scotland.

TO THE COUNCIL OF THE ROYAL AGRICULTURAL SOCIETY.

GENTLEMEN,—We, the undersigned exhibitors of steam-ploughs at Salisbury, are of opinion that the trial of those machines at that meeting was of an unsatisfactory character, and not such as was calculated to develope their merits, but rather, by putting them into exceptional circumstances, to injure them in the eyes of the public, and was not consistent with the importance of the subject, or a fair return for the large outlay incurred by us in exhibiting them there.

As the third offer of the Society's premium has again brought the subject under our notice, and as we cannot but think that the withdrawal of those schemes at present most prominently before the public from competition would be prejudicial to the progress of the invention, and would greatly detract from the interest of the Society's meeting at Chester, we would respectfully request that the Council would consider whether such terms and conditions of trial could be arranged and published previous to the day of entry as would enable these intending to exhibit to judge of the advisability of their incurring the heavy expenses necessary to such a competition.

As we observe that the judges, in their report of the trial at Salisbury, express the opinion that "the wording of the premium can never justify a judge in giving a prize whilst a plough is used," it is, we think, essential that it should be clearly stated whether any or all those plans which we represent are excluded by the wording of the offer of the premium from competition.

We would also suggest that to ensure such a trial of these machines as the importance of the subject deserves, a much longer time is necessary than can be given during the show week by judges who have a great many other duties to attend to, and that it would be of great importance that the judges of this department should have their whole time at their disposal for this subject, as no fair comparison with horse labour can be instituted except by lengthened trial.

The length of time that elapses before the publication of the judge's report and the adjudication of the prize also exercises a very prejudicial effect on the business to be done at the meeting. So much so, that, in our opinion, a machine known not to be competing for the premium, stands a better chance of obtaining orders on its own merits than one upon which a report is expected in a few months, and for which the public are likely to wait.

As, in the opinion of the editor of your report on Salisbury meeting, no adjudication need necessarily take place for some years to come, we would submit that there is not much inducement held out to us at present to compete at the next meeting.

If the Society would conclude not to offer the prize, but to expend a portion of the sum offered in a careful investigation of the individual merits of each machine, to be published in a report previous to the meeting, we should hail such a result with pleasure; but failing this, we would very respectfully request:

1st. That an explanation be given of the wording of the prize.

2nd. That arrangements be made for an extended and careful trial, and an immediate publication of the report of the judges.

3rd. That the adjudication of the prize should be fixed to take place, if possible, at a special council meeting during the week of the show, or at latest at the meeting of the council in August.

INFLUENCE OF EDUCATION UPON THE CULTIVATION OF THE SOIL.

SIR,—What sculpture is to a block of marble, education is to the human mind; the figure lies hidden in the stone, and the sculptor finds it: out of the rough stone he cuts a handsome figure. Education to the British farmer is a great accomplishment, useful, profitable, and ornamental; it teaches him how to calculate and to think for himself how he is to get his land the best cultivated at the least expense, and to know the value of labour upon a farm; nay, what ought to be performed by a certain number of men, horses, and oxen, in a given time. The more you educate the farmers the better the soil in England will be cultivated. Education leads a farmer to make hot land colder, cold land hotter, light land stiffer, and stiff land lighter; as in the Lincolnshire peat or fen land, for instance, where they mix the peat with clay, to make the peat stiffer. Education has brought forward all the new agricultural machinery, which has struck every enlightened farmer with admiration, and amazement to think what will follow. Half a century back a vast number of farmers required more cultivation than their ill-farmed lands, many of which grew more weeds than corn; nay, their land was half ploughed, half manured, and half cleaned in the weeding season. A niggard in labour is always a bad farmer. For the want of education agricultural chemistry is so little known amongst farmers, that many are greatly imposed upon by adulterated artificial manures. A more extensive acquaintance with the valuable articles which so frequently appear in the leading agricultural journals would enable every farmer to combine "science with practice."

Mill Field, Peterborough, Feb. 3. SAML. ARNSBY.

OXFORD FARMERS' CLUB.

The Monthly Meeting of this Club was held on Wednesday, March 10, in the Committee Room at the Star Hotel, when about fifty members were present.

The President (Mr. W. Thomson, of Culham) occupied the chair, and was assisted by the Vice-President (Mr. James Walker), of Begbroke Hill.

DRILL *v.* BROADCAST.

Mr. JAMES WILLIAMS, of Northcourt, expressed his regret that he should have disappointed the members in not bringing forward his subject at the last meeting, but at that time he was confined to the house, and could not attend; he thought, therefore, that the best apology he could make was to introduce it at this meeting. His attention had been drawn to the subject of depositing the seed of corn crops in the land in consequence of an article in the *Mark-lane Express*, in which the writer condemned the drill system, and advocated sowing broadcast. He (Mr. Williams) had used the drill for many years, and was satisfied that it was the best mode of depositing the seed-corn in the land; but, as others might differ with him upon that point, he was desirous of eliciting the opinion of this Club upon it. Mr. Williams then noticed the difference between the cereal and the leguminous crops, and showed the analogy which exists between the animal and vegetable creation. He then traced the history of the cultivation of the soil, and the modes adopted for depositing the seed in the land, from the time of the Goths down to the period of Oliver Cromwell, who laid the foundation of a different state of things, and when artificial grasses and turnips were introduced. He then noticed the system introduced by Jethro Tull, and the success which had attended it. Mr. Williams then entered into a variety of details explanatory of the modes of sowing broadcast, drilling, and dibbling, and said that he could come to no other conclusion than "That, as a general rule, the best mode of depositing the seed of corn crops in the land was by the use of the Suffolk drill," which he moved as a resolution..

Mr. JOHN PRICE, of Glympton, seconded the resolution.

Mr. WING concurred with the resolution, with some qualification.

Mr. WATSON spoke in favour of the drill system.

Mr. J. P. FIELD agreed, on the whole, with Mr. Williams, but considered that in hilly districts the drill could not be applied, and that dibbling by Newberry's drill, a very valuable implement, was preferable.

Mr. MIDDLETON preferred beans put in by hand to the drill, and said that, as a general principle, the Suffolk drill was the best, but not as a universal one.

Mr. COGGINS spoke in favour of the drill over broadcast.

After a few remarks from Mr. Osborn and the President,

Mr. WILLIAMS replied upon the whole question, and his resolution was then carried unanimously.

The discussion occupied some hours

PATENTS TAKEN OUT FOR THE APPLICATION OF TOWN SEWAGE.

In a recent number of our Journal appeared a *resumé* of the patents which have been taken out, from the earliest period up to the present time, under the head of "Drain Tiles and Pipes." We now propose to give a similar *resumé* of patents relating to manures. For the present, we shall select for notice those only which have special reference to *town sewage and the fœcal matter of our town population, their deodorization, and utilization as manures available for agricultural purposes.* And this narrowing of the subject—leaving the consideration of other manures to a future article—we are the more inclined to follow, as our remarks will be usefully introductory to, or elucidative of a review of two official reports which have been recently presented to Parliament bearing closely on the question of the disposal of our town sewage. This review may be comprised in one or two articles which we hope shortly to present to our readers.

To proceed with the immediate subject of our present paper, we find that the first patent having direct reference to town sewage was granted to Lewis James Armand Estienne, Jan. 9th, 1802, for converting "human excrement into a powder divested of all smell, preserving at the same time all its fertilizing properties." This was effected by gathering it into tanks, and allowing the liquid matter to be drawn off. The solid matter thus obtained was next dried in the sun, either mixed or unmixed with lime. It was next stowed away in heaps under a shed till it attained a temperature of 212 deg. Fahrenheit; it was finally crushed into a powder, which went into small compass. [No. 2,570, price 7d.]*

The next patent, in chronological order, was granted to Joseph Hehr Jerome Poitevin, July 17th, 1835, "for preparing a powder which is applicable to the purposes of disinfecting night-soil and certain other matters, and facilitating the producing of manure." This powder he obtained by calcining, when properly dry, mud of rivers or ponds, which contained animal or vegetable matter, capable of producing carbon by calcination. Where earths did not of themselves contain these matters, they were added previously to calcination.

On Aug. 10th, 1842, a patent was granted to Dominic Frick Albert, for a "manuring powder." This was obtained by mixing in certain proportions a number of substances together, as the ammoniacal liquor from gas works, the spent urical liquor in the scouring of woollen cloths, all sorts of animal refuse, cotton waste impregnated with oil, and, in fact, the refuse of nearly all our manufacturing or chemical processes. [9,442, 4d.]

June 23rd, 1845, is the date of a patent granted to Michel Antoine Bertin Burin der Buisson, for new and improved methods for the distillation of bituminous schistus and other bituminous substances: the mixing of some of the products of distillation with the residual ash in the retort, yielding a manure, the azote in which, the patentee stated, was considerably increased by allowing it to absorb fresh or coagulated blood, or any other soft animal matter, such as night-soil or brain, or liquid, such as urine. [10,726, 1½d.]

William Higgs, April 28th, 1846, obtained a patent for constructing tanks or reservoirs for collecting town sewage, and for solidifying and drying the solid matters therein contained. The patent also included buildings to be erected over these tanks, in which the gases evolved from the sewage were collected, and treated with chemical agents—the salts resulting from which crystallized or rested on spars or bars peculiarly arranged. Machinery and apparatus were also secured to the patentee for distributing and depositing chemical agents over the mass of sewage in the tanks. A fourth claim was for chemical agents for precipitating the solid matter in the sewage, and for absorbing and combining with the gases evolved from it, and with the solid matters precipitated. The substance used by the patentee to precipitate the solid matters was "hydrate of lime, commonly called slacked lime;" chlorine gas being used by preference, to condense or combine the gases evolved from the sewage, although hydrochloric acid gas is mentioned by the patentee as also useful for this purpose. [11181, 10d.]

The date of the patent granted to Edward Brown for "disinfecting fœcal substances," so as to preserve them in order to be manufactured into manures, was Feb. 20th, 1847. The substances stated to be employed for this purpose are, the "sulphate of iron, or the chlorides of sodium (sea salt), or of iron and manganese, or the nitrates, sulphates, and chlorides of lead, copper, zinc and tin, or pyroligneous acid, or the pyrolignites or the mother-waters arising from the manufacture of any of the before-enumerated substances, or coal tar, or schistous and bituminous extracts." The patentee also claimed the making of fœcal matters into manures by mixing them with an "absorbent powder." This was made by incinerating in closed vessels "coal or wood ashes, and earth, or street or road sweepings, and vegetable, animal, and mineral rubbish, such as sawdust, bone dust, and the waste matters of commerce, cotton mills," &c. [11,587, 4d.]

William Bridges Adams and Robert Richardson obtained, on May 24th, 1847, a patent for constructing at railway stations, close cisterns of slate, &c., into which the urine was designed to drain, and for using chemical ingredients to absorb the volatile alkali and other gases. [11,715, 2s. 1d.]

June 1st, 1848, is the date of the patent granted to Jasper Wheeler Rogers, for improved methods with machinery for the preparation of peat as a fuel, and in combination with certain substances as a compost or manure. For the latter purpose the peat-charcoal was to be added to animal excrement, in such quantities as to absorb the aqueous and volatile products, and to destroy the effluvium. [12,169, 2s. 5d.]

A patent was granted September 27th, 1849, to John Marriott Blashfield, for manufacturing manure from mud, by subjecting it to artificial heat, treating it with an acid, and embuing it with other fertilizing matters, these latter consisting of quick-lime, gypsum, sulphate of soda, nitrate of soda, or potash, &c., &c., these being ground to powder before being mixed with the mud. Sulphuric and nitric acids were employed. [12,790, 3d.]

The date of the patent granted to Louis Napoleon Legras was November 30th, 1849. The claims were very numerous. One had reference to the construction of water-closets, in which the solid matter was separated from the liquid. Another claim was for a vast number of substances to be used for disinfecting fœcal matters, and another for making a manure "resembling guano in its fertilizing qualities." This consisting of

* The number and price within brackets give the No. of the patent and its cost.

"bestial dung, road-scrapings, or street-sweepings, marl, fœcal substances, the residuum from the manufacture of schistus, or of peat, or wood-charcoal ground to powder, or of soot, marine salt, saltpetre, alumina, sulphate of zinc, and water," intimately mixed together, moulded into bricks, and dried; after which it is reduced to powder, and spread upon the ground when it rains. [12,869, 4s. 8d.]

A patent for "deodorizing every species of excretive fœcal matter or urine, at the moment when it falls from the body," was granted, June 4, 1850, to Paul D'Angely. The deodorizing substance employed was composed of fresh bark, rue, or wild mint, sulphate of iron, and pyrolignite of iron. The fœcal matter of the deodorization was converted into manure by being dried in a chamber peculiarly constructed, and reduced to powder, and finally mixed with "dried or burnt peat in powder, or with dried beasts' blood also in powder." [13,097, 5d.]

To Thomas Wicksteed, on Feb. 24, 1851, a patent was granted for manufacturing "manure from sewage water." This he effected by mixing it with milk of lime, and drying the precipitated matter by centrifugal drying machinery; by which the whole, or nearly the whole of the moisture was driven off, and the manure remained in a state fit for transport." [13,526, 9d.]

Oct. 16, 1851, is the date of the patent granted to Richard Dover for deodorizing sewage with an acid or acids, and for obtaining certain products therefrom. Amongst other substances, hydrochloric or some other mineral acid, iron filings, and chloride of sodium, are employed. After deodorization the sewage is filtered through charcoal, clay, gypsum, or peat, and is alone, or together with the following material, mixed with refuse animal matters, shale, marl, &c., to form "otner useful manures for fertilizing land." [13,755, 5d.]

Henry Stothert, in April 17, 1852, obtained a patent for applying a combination of materials to precipitate the solid parts of sewage to obtain a manure; and also for converting night-soil into charcoal, to be used as one of the precipitatory agents. The materials proposed were "fresh-made caustic lime, sulphate of alumina, sulphate or protoxide of zinc, compound animal and vegetable charcoal, obtained by distilling the precipitated matters of sewage waters, or by distilling night-soil, creosote oil of peat, peat-mould, tanner's spent bark, burnt clay, old mortar, or mixtures of such matters or other matters." [14,073, 3d.]

We conclude the subject by giving some mention of the peculiarities of those granted under the Patent Law Amendment Act of 1852. Under this act the first patent, relating to town sewage, is under date Oct. 6th, 1852, the patentee being William Armand Gilvee, the object of the patent a deodorizing powder, and the machinery or apparatus employed in manufacturing the same. The deodorizing powder is stated by the patentee to be prepared by the "combustion of the detritus of forests, lignites, vegetables, marine plants, or any ligneous substance, rags, and refuse of wool." The carbonized matters thus prepared are reduced to powder, and mixed with wool shearings in certain proportions. The fœcal matter is converted into manure by treating them with "decomposing powder, composed of the following substances, mixed together in certain proportions: molasses of sugar or the residuum thereof, slacked lime reduced to powder, sulphate of iron or zinc, and clayish magnesian earth" [No. 250, price 9½d.]

January 5th, 1853, is the date of the patent granted to William Bardwell, for constructing buildings, in a close chamber, on the basement of which a filter-bed is to be placed; in this chamber trays or shelves are suspended, containing sawdust or other matter moistened with dilute sulphuric acid. The sewage-matter, suspended by this agency from the sewage-water, is to be mixed with other matters, suitable for making manures [29, 8½d.]

Jacques Francisque Pinel obtained a patent, dated March 8, 1853, for deodorizing sewage-water by adding, in certain manner and proportions, sulphate of zinc, potass, alum, chloride of sodium, and sand. The solid matter thus obtained is again to be mixed with waste tan, pulverized chloride of sodium, nitrate of potass, soot, ashes, slacked lime, and muriate of ammonia [581, 2½d].

On March 15, 1853, John Thornton Herapath obtained a patent for precipitating the phosphoric acid and ammonia of sewage, in a comparatively insoluble state, by adding to it magnesia, or a magnesian compound. This addition is to be made at or about the time when the deodorization of the sewage is effected, through the addition of some chemical agent which will not decompose ammonia or its salts; but which, on the contrary, will combine with or absorb hydro-sulphuric acid, such as metallic sulphates, or metallic chlorides, or vegetable carbon [643, 2½d.]

To George Edward Doring a patent was granted, March 28, 1853, for "applying the salts and matter produced in the working of galvanic batteries"—generally treated as refuse, and thrown away—for disinfecting and deoderizing fœcal matters, and to render them available as manures [740, 3½d.]

In the patent dated May 20, 1853, granted to Thomas Isaac Dimsdale, a claim is made for disinfecting sewage and absorbing its noxious exhalations, by the employment of "a peculiar kind of peat-earth containing a salt or salts of iron or oxide of iron." Although no further claim is made specifying the peculiar kind of peat-earth, it is stated in the specification that "this knowledge of peat or bog-earth possessing those properties has led to this substance being very generally employed, particularly in Ireland, where it is a common practice to use peat in its raw state, or air-dried peat combined with ashes and peat-charcoal, to mix with manures, for the purpose of fixing ammonia and other volatile gases which are evolved from them" [1,252, 3½d.].

James Alexander Manning on November 29th, 1853, obtained a patent for "defecating and separating certain matters from sewage." For these purposes he employed "animal charcoal, alum, and carbonate of soda and gypsum." With the sewage precipitated thus, he mixed "waste charcoal or carbonaceous matter of various kinds, kelp, factory waste, common salt, or the refuse brine derived from the curing of provisions—gypsum, or phosphate of lime and horn-dust riddlings." In these operations the patentee used a peculiar form of precipitating vessel, and tanks with inclined bottoms [2,780, 6½d.].

A patent was granted, Dec. 10, 1853, to Allan Macpherson, for purifying sewage and other fœcal matters by using combinations of substances, such as peats of any description, whether in a high-dried natural state, or carbonized, in lumps or coarsely granulated, or finely powdered. Charcoal prepared from sawdust or refuse wood is also named; but peat charcoal is preferred by the patentee. A claim is also made for arresting, purifying, and deodorizing noxious gases in sewers, by placing in chambers made in the sewers, perforated trays or basket-work trays, with a mixture of peat charcoal. Where the sewage is discharged into a river, it is to pass through a barge, placed near the mouth of the sewer, and provided with deodorizing materials placed on gratings. The aqueous portion passes off to the river much purified, while "the contents of these lighters will be found to be a rich and powerful manure" [2,876, 4½d.].

To Robert Angus Smith and Alexander McDougall a patent was granted, Jan. 20, 1854, for improvements in deodorizing and disinfecting sewage by employing, alone or together, a combination of magnesia and lime, with sulphurous acid and carbonic acid, "either in an acid or alkaline state" [142, 3d.]

The date of the (second, third, and fourth) patents granted to Thomas Wicksteed, is January 26th, 1854. The first of these is for moulding the fertilized matter of precipitated sewage into perforated bricks or blocks, in manner similar to that employed in ordinary brick-making—the hollow perforations facilitating the drying of the bricks. The second of these three patents refers to a method of precipitating the fertilizing matter of sewage by mixing it with lime and finely-divided charcoal: the two substances are mixed in water, and a stream of it is made to flow into the sewage-water, by means of a pump—another pump supplying the sewage-water. The third of these patents refers to the construction of reservoirs for the deposition of the precipitate from sewage-water. These are arranged so as to cause an equal flow from all parts, with the exception of a portion at the bottom which receives the precipitated matter. The velocity is regulated so as not to prevent the subsidence of the precipitate. The water is thrown off the precipitate from the bottom of the reservoir into a well by means of an endless screw. The precipitate is raised by means of an elevator or Jacob's ladder, in such a way that the precipitate is raised without contact with the supernatant liquid [192, 3d.; 193, 3d.; 194, 1s. 1d.]

The date of the (second) patent granted to John Thornton Herapath is March 17th, 1854, and it claims the employment of coke obtained from the so-called Boghead coal or Torbane-hill mineral, "either before or after the aluminous ingredients of the coke shall have been extracted by an acid or other chemical." This coke to be used either for drying up precipitated sewage, or using a stratum of it, through which sewage, &c., is allowed to pass or percolate [638, 3d.]

The date of the (second) patent granted to James Alexander Manning is March 27th, 1854; and is for "improvements in the treatment of sewage." The sewage is to be mixed with the "soft sludge" from the alum works: the contents of the reservoir are to be agitated, and during agitation powdered caustic or unslacked lime and animal charcoal are to be thrown in. This alum "sludge" is the deposit during the first boiling down of the rough liquor obtained from alum shales in the manufacture of alum, and which deposit consists essentially of basic and other sulphates of iron and alumina" [709, 3d.].

George Anderson, on December 23rd, 1854, obtained a patent for purifying sewers from noxious exhalations; and this he proposed to effect by using a pump, fan, or other exhausting apparatus, to force the vapours in contact with deodorising materials. The materials named by the patentee are, "lime as used in the gas works, peroxide of iron or other metallic salts, or dilute acids, or acids held by peat, coke, gravel, charcoal, sawdust, or other matter." The product obtained to be used as a manure, or applied to other useful purposes [2,715, 3d.].

The date of the (third) patent granted to James Alexder Manning is August 7, 1855, and is for the employment of "alum slate, alum shale, alum schist, alum ore, and other aluminous minerals and earths, as a precipitatory and clarifying agent for cleansing sewage matters. The method to be employed in preparing the shales is described. In addition to this alum liquor, powdered lime and charcoal are employed. The sewage is stated to be greatly improved in value for agricultural purposes by the addition of the alum shales." [1,786, 3d.]

Having thus reviewed very briefly, the various patents taken out for the deodorization and utilization of our town sewage, we shall be prepared to enter into the consideration of the relative values of manures prepared by some of the processes described, and the chances—favourable or otherwise—of their being employed on the large scale. This consideration we propose to take up, in conjunction with the *future prospects of the application of town sewage to agricultural purposes*, in noticing two important reports recently published, and to which we referred at the commencement of the present papers.

"LOIS-WEEDON" WITHOUT THE SPADE.

Lois-Weedon wheat-growing! How many years has it been known to the public, and how many agriculturists have adopted its advantages? In seeking answers to these inquiries, we have been compelled to reflect that one of the farmer's chief faults is a scepticism in regard to offered improvements, when they involve fundamental changes in his practice; and pioneers in farm mechanics, or discoverers of new systems of husbandry, should have fortitude almost like that of brave Bonnevard, of Geneva, in order to "possess their souls in patience," through years of distrust, neglect, or opposition. Why, can it be believed, the reverend Mr. Smith's pamphlet, detailing his practice, its cost and profit, appeared eight years ago! and he had then sufficient experience to warrant his recommendation of the plan to others; for he had thrashed his third harvest, grown year after year on the same acre of land.

The first wheat crop on the now world-renowned "clay piece" was sown in 1846; yet it was not until November, 1849, that the talented and assiduous cultivator felt (with that modesty characterizing all his works) that he would be justified in publishing his success. Thus prolonged and tedious must agricultural experiments necessarily be! So long has the husbandman, who sows *new seeds* in hope, to wait ere the fruits of his thoughtful ingenuities in preparing the soil, and his prudent nurture of the rising plants, reward him with more than promise! The first harvest was not measured; the second and third gave each thirty-four bushels per acre. With wheat at forty shillings a quarter, and straw at forty shillings a ton (for being grown without manure the straw was sold), the tenant's profit was found and proved to be at least four pounds per acre.

Now, it will be remembered that, in 1849, the general feeling among farmers was that, under the circumstances of the times, it was impossible to grow wheat crops that would pay; and, again, there were a great many unemployed labourers dependent on parish sustenance; and the new method of wheat culture by the spade offered not only profit to the farmer, but to the workmen employment and support. These considerations prevailed upon Mr. Smith to break silence with his simple and attractive "Word in Season;" "impelled," as he says, "in fulfilment of a duty which all owe to their fellows, to make known, I trust not presumptuously, what is no longer experiment, but experience, of a most profitable system of growing corn." When we infer a hasty conclusion from a single experiment, and

urge it as a settled truth, we must expect to meet with incredulous and closed ears; but when you have quietly tested a system for three long years, accurately booked, weighed, and measured, and calculated your profit with the certainty of demonstration, it is natural to suppose that the proposal of a simple though novel series of tillage operations, promising so handsomely in a time of despondency and bad prices, would be eagerly caught up, and (with the best kind of gratitude, appropriation, and imitation) at once tried in every province of the kingdom, and applied with ready and clever adaptations to all soils and varying circumstances. Now, Mr. Smith has no "interest" in the extension of his husbandry: he has never pushed it before public attention by any form of advertising, but simply given us annually his most telling, because most truthful, statement of the facts of his management and success; and it must seem hard to him to find only a few instances of Lois-Weedon husbandry here and there, after all these years of advising agriculturists for their own good. However, he has persevered with his own cultivation with the happiest success, and an ample profit; and if others do not choose to venture on the practice, they themselves are the losers. Mr. Smith has *not* been obliged to dig deeper for every succeeding crop; but the last two years' crops have been much greater than the previous average, though the double digging had been discontinued, and the fork worked only 10 inches deep. In fact, there is not one of the numberless objections, scientific as well as practical, raised against the system, that has not been proved untenable. It remains true, that wherever the plan has been found to fail, the rules have been violated—unless we except Mr. Piper's case, about which more particulars are desirable; and we have instances of success to corroborate the original testimony. Mr. Jones, of Lois-Weedon, published the satisfactory results of his practice; and Lieutenant Goodiff, of Granard, in Ireland, also made known the success of his trials on a small scale. In the winter of 1854-5, Mr. H. Dixon, of Witham, Essex, was double-trenching five acres for the purpose; but whether his wheat-growing answered, the world has not yet heard. R. Calwell, Esq., of Belvedere, county Down, tried 14 acres in the year 1854, and extended the breadth to 29 acres in 1855, the first year's crop leaving about £3 10s. per acre over and above the expenses, rent, profit, &c. In 1854-5-6-7 an acre of dry gravelly land near Reading was under a modified form of the Lois-Weedon system; and, though found to yield three quarters annually, would not have been remunerative except for the high price of produce. One or two quarters less than the land would grow in ordinary good culture is of course unsatisfactory; but in this case, some of the most important conditions of management were neglected. Mr. Piper's lately-published results are very unfavourable, as he got only five sacks of corn and half-a-ton of straw per acre; but the details of his management are not at present forthcoming. Lord Rayleigh has grown two acres of Lois-Weedon wheat, near Witham, for five years successively, without manure; the average yield being 44 bushels. Mr. Lawes has made the system fail at Rothamsted on a good loamy soil; but merely, we believe, in consequence of not adhering to Mr. Smith's instructions. We remember to have seen a large field of three-row wheat in Kent, last year. In Lincolnshire we knew a cottage plot under the same system; and last spring passed a field by the roadside where the farmer was rolling his triple rows with the wheels of a cart, the horse walking along the fallow intervals. A spirited agriculturist in Norfolk has for several years grown wheat on a plan much resembling that of Lois-Weedon. On a strong loamy soil he had wheat in triple rows, with a row of potatoes planted in each interval; but this was too troublesome in cleaning of couch, &c. His crops of wheat, with intervals fallowed for bearing wheat the next year, have been very heavy and productive; and there is no doubt they are abundantly profitable. He applies manure besides tilling the intervals; and is so satisfied with the practice (having tried it in portions of many different fields), that this year, we understand, he has sown nearly all his wheat land in three-row stripes. Accurate accounts of work done, and other items of expense, he has not been at the trouble to keep faithfully; but the produce has been so large and obviously remunerative, that his experience and management ought to be described in detail for the example of others. Let us hope he will come forward with a letter or address on the subject.

No doubt many cases of Lois-Weedon husbandry are known to Mr. Smith; but the above list, together with six acres in France, which alluded to below includes all we have yet heard of, with the exception, indeed, of a piece begun last year by ourselves.

In the following extract, have we lighted upon a foreign disciple of the Rev. Mr. Smith, of Lois-Weedon? or a contemporary and independent expounder of Tull's principles applied in the same manner to the culture of wheat? In Mr. Musgrave's "Ramble through Normandy," published in 1855, and describing a tour made in the autumn of 1854, occurs this passage: "While on the subject of foreign husbandry, it is worth noticing the fact that in the heart of Normandy I saw upon land of no very rich quality a heavy crop of wheat grown upon a tract of six acres that had not been 'mended' for nearly as many years. The owner himself occupied it. He was not a needy man; but being a breeder of sheep and a grower of fruit, he laid no great stress upon arable land, and cultivated his grain crop *scientifiquement*. The *science* lay in the preservation of a width of well-tilled unsown intervals of three feet, marking out the corn; and in constant resort to spade labour, which, the wages being low, had, in this instance, superseded the customary employment of horses and ploughs. The horse-hoe, spade, fork, and presser, turning up the clods to crumble, year after year, under the action of winter's wind, rain, and frost, had been followed up by supernal aids in spring and summer; for man having found labour, his Maker had contributed softening dews and balmy breezes, charged, as they must have been, with the treasures of nitrogen, and penetrating deeply the porous soil. Nothing but this winter and summer fallow, under the advantages of depth and constant pulverization, and such aid from the stores of heaven, could, in the absence of all manure, account for the self-same breadth of land yielding successive white crops in the abundance apparent in every part of it.

"I dare say the English tenantry would laugh at the bare mention of land yielding abundantly without manure; and the proprietor's face would lengthen if he surmised his broad acres were held by an occupier that never sent a tumbril of dung into the stubbles. But there is one party in the country who would be only too happy to see the system perpetuated; I mean the labourers, who, being sent on to the ploughed field to trench it with the spade, bury the exhausted top-soil, and bring the lower stratum of fresh soil to the surface, would throw all the worn-out loam to the bottom, and bring clean, fresh, vegetative mould to the surface; the depth and quality of the active soil being hereby wonderfully improved, and the number of hands employed being triple of the average amount of labour. An aid like this to ordinary tillage would reclaim the most unpromising pieces. But, in our variable climate, the process of cultivation must necessarily be expeditious,

and two horses can do in one day the work of twenty men. Hence the paramount obligation to use ploughs, and not spades; and to create, through the medium of nourishing agents, the principles of new vegetation: for, as we cannot replace every year as much as we remove from our fields, in the form of produce, and since we exhaust the finest soil by repeated cropping, we are bound to replenish with fertilizing substances, and to bring into operation, by artificial applications, those active elements (hydrogen, carbon, oxygen, and nitrogen) which the Divine husbandry above-mentioned would employ, were large and little farms exclusively cultivated on the principle I have described. The theory is most truthful, and for that reason I have adverted to it; but the practice is impossible, not only in respect of cost, but of the climate; and therefore the healthful and refreshing ammoniacal aroma sent forth from a field well ploughed, harrowed, and manured, in the most approved fashion, will be as acceptable to my critical nostrils as ever."

The author appears to be unaware of Mr. Smith's doings at Lois Weedon, and he seems to imply that this Normandy farmer had practised the system ever since the year 1848 or '9. If so, it will be exceedingly interesting to find that two scientific cultivators, so far apart, should have independently evolved identical methods of growing wheat in rows, and trenching and horse-hoeing the fallow intervals; for, though Mr. Smith began operations in 1846, the methods and results were not made public until the winter of 1849 50. It may be, however, that had the above account been more explicit as to dates, costs, and quantities, we should have found that the "Word in Season," so little heeded in our own land, crossed the Channel and went at once to the heart of this Normandy husbandman, who "cultivates his grain crop *scientifiquement*."

At any rate, we have here a capital corroborative experiment in the Lois Weedon system; and we by no means share in the author's opinion as to the impossibility of carrying out the principle, owing to the great cost of labour involved, and the want of time in our climate to accomplish the digging. Mr. Smith has already progressed a long way towards reudering himself independent of manual spade-work, by his invention of a rotary digger, used in connection with the ordinary plough; and, as we shall relate in another paper, there are other methods of endeavouring to perform the requisite tillage by horse-labour. Let us try to make *traction*-implements suffice; and then we shall not only cultivate with the greatest economy, but *steam* may be employed as the motive power, and machinery be more largely our fertilizer instead of manure.

AN ENGLISH FARMER IN FRANCE.

Sir,—According to promise I will give you my impressions on all here that is novel and interesting to an Englishman. As a farmer of 30 years, perhaps some account of the agriculture may be acceptable to your readers; but I will not confine myself to that alone. I hope I am unprejudiced, and can I possibly find anything worthy of adoption I will not fail to note it. In many parts of England there are many things agricultural, which appear strange to a visitor from a distance, but I make it a rule never to condemn too quickly. The more ridiculous a custom appears the more certain you may be there is some reason in it. In this frame of mind will I view here all I see, and if any of my brother farmers at home find amusement in my homely lucubrations, I shall feel repaid.

First, a few words to any who may like to do as I am doing, viz., enjoying health, amusement, and I may add information, at a small expense. By all means take your passport first. I did not, and so had to go to our Consul here for it; the charge is 5s.; but whatever number form your party one passport is enough. I prefer entering France by Dunkirque, because it is its most northern part; its richest in land, in population, and in manufactures. I went on board the boat at the Tower at 12 at night, by 12 o'clock next day, Oct. 16, I was here. The sea was as smooth as a pond, and the sun as brilliant as summer; the cost 10s. for the boat, and 2s. for the steward. The coast of France in this part is not very interesting, as all the country is as level as Romney Marsh; but still the first approach of a stranger to a foreign part must always excite and interest him. The moment I arrived no doubt could possibly exist that this was not my native land. The men, the houses, even the shipping was so unlike our Thames; one-third of all the men wear a uniform; nothing public can be done without it. Our first acquaintance, of course, are the Custom-house people; there are 175 "douaniers," all dressed like soldiers, with muskets, &c.; the police in green clothes and cocked hats! ! and swords; then the 800 soldiers, as a whole regiment, is here always; the priests in black gowns and hats, like our Quakers; the Sisters of Charity; the gendarmes in their most picturesque dresses and cocked hats, looking like the soldiers of Frederic the Great; and all the women, except the highest classes, without bonnets; all these odd costumes make the streets appear to a stranger almost like a carnival. The overhauling of your baggage is soon over, and you go to your hotel. The two best in town charge 1s. 8d. per day for your chamber, 1s. 8d. for the table d'hote, and 1s. 3d. for breakfast; so your expenses you know at once; if you like to stay a month they will do it cheaper. Everything is clean, people attentive, and the beds the best I ever slept in; they are differently stuffed to any in England; even the poorest have good beds of dried leaves. On having arranged your room, you have a cup of coffee and Cogniac, which always join company here, and have a look at the town; streets straight, houses high, rooms all lofty, roads and paths paved alike, most unpleasant to the feet, plenty of public buildings, large churches, and last, though not least interesting, the fortifications, which, of course, now only are of use to enable a small duty to be collected on all eatables and drinkables that enter the town. You return to dinner at 5 o'clock, and find for your two franks soup, fish, meat, poultry, and sweets and beer. Wine is extra. Common red wine, not so good as our cider, 1½ franc per bottle. Cogniac is about 12s. a gallon; and eau de vie, which is principally the spirit of the beet-root, half the money. I like it, and it agrees with me; but it is not considered wholesome. So far my friends would have been here twenty-hours, and have seen the town itself. They would now begin to look at other matters. The first thing that would strike the eye of a farmer is the extraordinary waggons, and mode of attaching the horses to them. The waggons of the town are narrow, very long, and not a foot from the ground: very convenient for the merchandize here. The front wheels are not above 2 to 2½ feet high, with a short axle, to enable them to turn in a small space, as they are altogether in front of the waggon-body. The horse is in shafts, and draws from a bar, like a chaise, to give

play to his shoulders; and, except that we are astonished to see one horse draw such heavy loads on such low wheels, the whole thing works appropriate for its purpose. But the country waggons are what excited my surprise: long, narrow, and clumsy; as they are liberal of wood, but careful in use of iron. Small lock under front wheels, with axle two feet shorter than the hind one. Never painted, and loaded occasionally with six or seven of our tons to three horses abreast. Two tons per horse is considered a fair load; but the horses and roads are both excellent, and the latter without a hill for many miles. In lieu of shafts, this waggon has a pole half the length of a coach-pole, at the end of which the horses are hooked on to whipple-trees—three for two horses, and five for three, as we have at plough in some parts of England. So that no one horse can draw more than the others, the driver walks at their heels with one rein in his left hand, and his right on the pole, as he has to guide it and assist in stopping it; but in passing bridges or other descents he screws up a wooden bar, which catches both hind-wheels. The horses are the most docile I ever saw, and certainly these ungainly waggons follow well. The harness is as simple as our plough-harness. I have endeavoured, but uselessly, to find out the reason for this placing the horses so far from their work. I believe it is that all here are Flemish, staid, sober, money-making people, who are satisfied to do as their forefathers did; and the only other reason is, that, the harness being all alike, they are momentarily detached from one job to another, or an extra horse added over a bad bit of road in their fields. But from this strange combination of horses and waggons two hints may be taken. Decidedly three horses with whippletrees more equally divide their work than with us, and more easily start a dead pull. I have not seen one horse fret, and another hang back, as common at home; and I see no reason why we should not attach them in the same way. Some may think one-horse might pull the other back till his hocks were on the front wheel; but if we had a pole (or two poles for three horses), the pole pieces would prevent this. How admirably these bars are adapted to the three-horse omnibuses of London, as they *must* all draw alike. As regards the men, ours might imitate their sobriety, cleanliness, and kindness to their horses. I have not seen one horse struck; they all (gentlemen's coachmen too) crack their whips backwards and forwards, that is, twice to our once, and are quite proud of the horrid noise. Fancy a nobleman's coachman doing this in Hyde Park! The other hint we may take from their collars: The hames are attached to them, and go all round. They open at bottom, with a hinge at top, so have no occasion to be thrust over the head. They are quickly put over the neck. At the bottom each hame has what I can only describe as half of a door-hinge; these are pressed together, and a pin inserted, and all is done is most quickly. We all know the trouble in England with colts and bad-tempered horses to get the collar over the head. I must think theirs the better way. All collars, whether nags or cart-horses, are the same.

The next attraction is the splendid asses; I did not know there was such a breed out of Spain—the Flemish ass, over twelve hands high, fat, handsome, and good workers. They never are shod, though they work on the roads, and are of the value of £12 to £14. I could not believe it, till all told me the same. The environs of Dunkirque for three or four miles are devoted to market-gardening, and principally managed by women, who come into the town with enormous carts of vegetables drawn by these donkeys. They think nothing of half a ton weight being drawn by one; and I saw a man riding on one with a barrel slung on each side of his saddle. But the most picturesque thing is the sight of acountry-woman riding to market on her donkey. She has a saddle of sheepskin, with the wool on, reaching from the withers to the tail. She sits sideways, and has behind her, as on a pillion, a tub of butter, &c., most beautifully clean; and herself without a bonnet, but instead a large cap as white as snow, completes as rural a subject as artist would wish to sketch. The barges of 200 tons on the canals which traverse Belgium and France I think complete the objects of greatest interest in the town.

I should fancy no foreign agricultural subject can be more interesting to your readers than an account of the *bette-raves*, and the manufacture of them into sugar and alcohol, as sugar and spirits we all consume. The former, it is often said, is unprofitable to produce in our West India colonies, and ought to be supplanted by cotton. To say nothing about much of our imported sugar being the result of slave labour, the spirit is doubly a matter of anxiety now that the vines (though better) are more or less affected by disease. It is a root well adapted to our land; and it does seem extraordinary to me we have nothing of the kind. Whether we are prevented by law I know not; and if some of your correspondents would inform me the reason, I would feel obliged

It is the main paying crop of the farmer here; and a most profitable one too, producing great weight, bearing an unlimited demand (except at this moment), and fetching always a remunerating price. Just now there is a complete panic in the trade, sugars having dropped in price, but more particularly spirits, which have fallen nearly half during the last six months, caused by the great crop of beet, the bad quality of them, and the increased supply of alcohol from the vine districts; consequently the roots, which for the last four years have fetched from 14s. to 18s., and in October 21s. per ton, are now a drug at 2s. 6d., and, after March, will be worth nothing, as every month after Christmas they lose some saccharine. So you may imagine the state of the trade and the feelings of the producers.

But, first, as regards the cultivation. The land here being all a splendid loam, is extremely applicable to the production of these roots; but, like our mangel wurzel, they are suitable to clays. Indeed, French chemists tell us that the most sugary roots are produced on clay with a deep top-soil, and containing flint. I need not say, the land requires to be clean: all here is always so. It is ploughed *very deeply* in autumn, well dunged, and sown from the middle of April to the end of May. The quantity of seed required is about 8lbs. to the acre, as it is either drilled or dibbled, with the thumb, one foot apart. The cost of it is about 5d. per lb. It is not liable to be attacked by the fly; and a plant is nearly certain. When the leaves are as long as the little finger, it is singled out, so that each plant stands exactly one foot apart each way; as if thinner, they grow too large. The smaller ones producing the most sugar, they are refused by the manufacturer if weighing much more than 4lbs. each. During the summer of course it is frequently hoed. The leaves are not taken off for cattle during the progress of its growth, as is sometimes done in England with the wurzel; and in September, when the tops droop and turn brown, it is time to lift them. This is often done by the acre, at 16s. I mention this to show how well the farm-labourers are paid here; but it requires to be most particularly well cleaned, which they do for this money, as also cut off the tops and *crowns* (which contain no sugar), and throw the roots into the waggons (carts are very seldom used here). The crop is about 22 tons per acre; often more. If not sold at once, it is clamped, and well covered with earth. Barns, cellars, and walls have been tried, but none do so well as the clamps, which are left open for some time along the whole ridge, to permit every particle

of evaporation to escape. In the neighbourhood of a factory whole fields may be seen covered with clamps, the reserve stock of the manufacturers. There are many sorts of *betteraves*, but the two sorts in general growth are the white Silesian, and a variety of the Silesian with a red skin and white interior. It exhausts the land more than potatoes; but though sold off the farm it has the good quality of returning to it as much manure, perhaps, as if wholly consumed on it (indeed the latter would be impossible, as in its raw state it is a dreadful scourer), as all the refuse after pressing—that is the farinaceous part of the root—is eagerly bought by the farmer at from 8s. 4d. to 13s. per ton for his fattening bullocks, cows, and sheep; to the first named he gives 100 lbs. weight per day. Now, as we know a bullock will eat 4 bushels of swedes in twenty-four hours, we may calculate at all events that it stands as 2 to 5 superior in quality to raw roots. This refuse, which looks like pressed rags, and is in flat pieces about as large as the palm of the hand, has also the peculiar quality of *improving* by keeping in clumps (well trod) for two or three years, enabling the farmer to lay in a store when a drop occurs in price. A great comfort to a stock-keeper to know he has always a reserve of food for all weathers and bad seasons. The crop that follows is wheat; hot summers suit it best.

It was a long time known to be a saccharine root in France, but its usefulness was not developed till 1812, when the Government passed a decree permitting the growth to the extent of 250,000 acres, and exempted it from all duties; in three years it ceased to give this encouragement to the growth, but its prosperity progressed; in 1827 there were 89 factories, producing 8 million pounds of sugar; in 1836 more than 500, making nearly 50 millions; in 1837 they put a duty on it of a half-penny per lb., and added another farthing in 1839. From thence to now it has continually advanced.

I introduced myself, one fine morning, at a factory about a league from Lille, as an English stranger, asking the favour of an inspection of it. The owner most politely acceded to my wish, first making me partake of his *déjeûner*, the usual eleven o'clock breakfast of chops, coffee, and wine. This hospitality I felt the more, as it was only the second time during my three months stay I had the opportunity of enjoying it, as all classes are alike unfortunate in their ignorance of our truly English custom of inviting all who cross our threshold to take something, from a glass of beer to a seat at dinner. He then showed me his sugar and his distilling processes; it took three hours to go over it, and a most interesting mass of machinery it was.

The commencement of the process is as follows: The loaded waggons are weighed, as they enter, on a weigh-bridge, and the empty vehicle deducted; the roots then well-washed by steam-power, and drawn into the macerating machine by an archimedian-screw; after this is very minutely performed, the pulp is pressed in hydraulic presses, and the remains in the press bags are instantly ready for sale to the farmer. 180 pints of juice are extracted from 2 cwt. *betteraves*, which goes into a reservoir tolerably impervious to air (which is detrimental) till wanted. It is then heated in boiling-pans to 60 degrees (I am not sure if this means the same as 60 degrees in England); and a solution of lime is thrown in at the rate of 1 part to 20 parts of juice, and a little sulphuric acid to neutralize any excess of lime. It is then filtered with animal charcoal, which also reduces the colour, and then passes into boiling-pans to evaporate; then a second evaporation and another concentration; and then a third filtration with charcoal; then boiling, and at this stage it passes into coolers and begins to crystallize. The remaining processes it would be tedious to your readers to have described.

	£.	s.	d.
One ton of roots will produce 1¼ cwt. sugar, brown, worth, duty included	3	10	0
And also ¼ cwt. molasses, worth	0	2	0
And 2½ cwt. of refuse for the farmer, worth	0	1	8
And 17 cwt. of juice.			
	£3	13	8

The duty here is two-pence per lb., and it is usually sold at 6d. (not now), which is considered a profitable price.

We undersell the French in most manufactures; so it is fair to suppose we can in sugar, if we please. We were told we were to have free trade, to be totally unshackled, whether it was sugar or tobacco we wished to grow.

The molasses are distilled, of course, and some potass made from the refuse.

Many distilleries are expressly for extracting spirit from the root itself: a ton is expected to make 10 gallons. The whole of the refuse from this is useless.

Beet-root sugar-refining is also carried on to a great extent; the decrease in weight by the process is one-fifth.

White sugar is retailed by the grocers *now* at 8d. to 9d. per lb. *Remember I always write in English measures and weights.*

It is allowed to be a most lucrative trade in all its branches. It is carried on over the whole of this northern department. Valenciennes is the very heart of it; but much is also done near Paris, Marseilles, and on the frontier near Switzerland.

The alcohol is sold for mixing with the Geneva cognac, and also for making *eau-de-vie*; also for varnish, and many descriptions of manufactures requiring cheap spirit. It has been sometimes exported to England, but is not allowed at this time.

Spirits are sold by all grocers, Geneva and *eau-de-vie* at 6d. to 7d. per pint; the licence for which costs £2 1s. 8d. per annum.

I cannot finish this letter without remarking on the cheapness of spirits here, and the general sobriety, and comparing it with the contrary of both in England. It cannot be that the climate is warmer, for there is no hill between this city and the Polar Seas, and it is indeed cold here. The unrestricted sale here, at all events, does not produce drunkenness.

AN ENGLISH FARMER IN FRANCE.

Lille, March 4th, 1858.

QUICKS (CRATGÆUS OXYCANTHA) Common Hawthorn—for general, or, more particularly, for agricultural purposes, are not to be excelled. Their culture is too well known to require any particular comment, did we not see so often erroneous practices carried out; for instance, the planting upon high banks, which dries them up, and, when crumbled down, leaves them exposed to the inroads of cattle, &c. No better example is taught us than those planted by the sides of railways—the Great Western, for instance. There you see them properly planted, well cleaned, and properly sheared—in fact, hedges worthy our best attention. We have often heard Mr. Sharp complain to the unfortunate nurseryman from whom he purchased his few thousand Quicks, that many of them died, when perhaps, as is very often the case, no care was taken in the first place to give them proper accommodation. First, then, the soil certainly, in every instance, should be trenched; and if manured, the plants will repay it. Always plant, if the nature of the soil will permit, upon the same level as the field, not upon elevated banks. Place a fence—constructed with piles about eight or nine feet apart, with two horizontal rails—for protection. Then select

two or three years' transplanted plants; and when the plants are well established, say the second year, cut them down within six or eight inches of the ground. The following year cut them to about two or three feet, according to their strength; then the hedge is made. Establishing a good bushy bottom is the principle to aim at. It is a very bad practice to thrust large bundles of bushes into decayed places or gaps: it makes the place larger. It is far better to select strong transplanted three or four-feet trees to fill up with, and give them temporary protection, and thus make up the slight deficiency. Never allow the hedge to produce timber, as you very often see; for after it is cut down, besides the sacrifice for one or two seasons, the old shoots generally throw up strong luxuriant thorny shoots, and form a bad bottom in return. Should the above fence not be practicable, a low bank might be made, putting in plenty of plants between each layer of turf and soil; this last suggestion does not make so perfect a hedge as the former described plan.

ECONOMY IN BREAD.—No. 5.

MAIZE BREAD.

SIR,—Maize may be considered as nourishing as wheat, but will not rise like wheat into light bread; and maize flour raised with wheat flour is neither so pleasant in texture or flavour as wheat bread alone.

The maize requires first to be boiled to pulp, like rice, and so made up with the wheat flour into dough. The following recipe has been much recommended:—

MAIZE BREAD.

To 1¼ lbs. of maize meal add a gallon of cold water (soft) and stir it up well; let it settle, and skim off the husk which floats on the top. It should then be boiled for three or four hours, if possible by steam, or the pan inserted in another containing water, boiling, which will prevent its burning to the bottom; and covered, to prevent drying away. If the meal be good, it will have absorbed all the water that has not evaporated, and have become a thick porridge; the produce of the Southern states of America will take one-fourth more water than the produce of Europe.

This may be made up into dough with 14 lbs. wheat flour as the rice in our last—yeast and salt added—and divided into loaves as usual.

This has been tried here, but did not please so well as that with Carolina rice. On the other hand, the Americans themselves are very fond of "Mush," a sort of maize porridge, made as follows:—

MUSH, AMERICAN.

"This is made in different ways; but the easiest mode is that which resembles the making of starch or arrow-root. Put five pints of water over the fire, in a pot or skillet; then take one pound of Indian meal, well sifted from the bran, and mix with a little cold water so as to make a thick batter; add salt. As soon as the water boils, add the batter, stir it well, and keep it stirred and boiling for at least twenty minutes.

"It should be about the consistence of hasty pudding, porridge, or stir-about; and may indeed be made in the same way. Take it up, and eat it with milk, butter, sugar, or treacle.

"This is the most manageable and convenient of all the preparations of maize; it is used daily in a large number of American families, and considered a most wholesome diet. What is not used at one meal, is cut into slices and fried or heated upon the gridiron at the next meal, and eaten with butter or treacle."

This worked up into dough with flour would be much like the maize bread given above, requiring, of course, more water to work in the wheat flour. And the proportion of maize may be much increased for those who like it. I have a statement of 38lbs. of bread from 14lbs. of flour with 7lbs. of maize. But for those who object to the maize flavour it is to be corrected with rice.

Maize bread with rice, and the compound of the two with M. Mege Mouries' improvement, to obtain the maximum excellent loaf at the minimum cost, the object of all these letters, are intended to form the subjects of our next.

I. PRIDEAUX.

BUTTER-MAKING IN WINTER.

"Winter butter" has no very enviable reputation anywhere, and compared with that made in June, seems an entirely different article. Of course there are reasons for this—let us enumerate some of them.

1. The character of the food is changed from green and succulent herbage to dry hay, or, more generally, cornstalks and straw. There is really very little butter in the latter.

2. The season is changed from mild and warm to cold, bleak, and uncomfortable. There is a constant demand for fuel to keep up the animal heat; this is partly at the expense of the butter product.

3. The management of the milk becomes difficult. If kept in a cellar, and a little above freezing, the milk becomes bitter before the cream rises; if allowed to freeze, the cream rises at once, but is injured in quality, and will produce very white butter; if kept in the kitchen pantry, when very warm during the day and cold at night, it does not rise well, and is apt to be bitter and acid.

Other reasons might be mentioned, but they will readily suggest themselves to the reader. Let us see what can be proposed to remedy the difficulties.

1. Feed well—not dry food alone—but grain and roots, as a substitute for grass. Carrots, turnips, beets, cabbages, etc., are all useful in keeping up the quality of the milk. Let their fodder be cut, and some nutritious slops be provided, if roots are not to be had; and it is well to cut the fodder in any case.

2. The comfort of cows should be carefully attended to. While they suffer from cold and filth, or foul air, they cannot yield as good milk as when in warm, clean stables, or in well-littered and sheltered yards. Water should also be provided—it is the more needed when dry forage is consumed—and it should be so arranged that every animal could drink at will. A supply of salt is also necessary.

3. It is difficult to get a proper temperature for raising cream perfectly in winter. Some butter-makers scald their milk when first drawn from the cow; others let it stand twelve hours, and then place the pan containing the milk in a larger one filled with boiling water, and allowing it to stand twelve hours longer, find the cream raised perfectly. It is said that more and better butter can be made in this way than in any other.

Churning in winter, as usually managed, is often a serious operation. The cream stands too long generally, becoming very sour and bitter; or, it is too cold and froths up, filling the churn, but producing no butter though churned for hours. Let the cream-pot sit near the fire for a few hours before churning, stirring it occasionally that all may get warm alike, and when it is at a proper temperature, 55°—feeling a little warm to the finger—the churning will be an easy half-hour's job, and the butter as yellow and hard as the season will admit of.

We have found that cows generally gave better milk when fed on well-cured corn-fodder, than on second-rate hay, and with "a mess" of roots, apples, or pumpkins, would yield milk of very fair quality. Attention to securing a supply of proper food for cows, and better care of them, would go far to redeem the name of winter-butter from its present character.

J. H. B.

MANURING ON THE SURFACE.

Surface manuring is no new idea; yet if our memory serves us, the practice is almost universally ignored by agricultural writers of the present day, as a method of manuring. It is acknowledged as a very good thing to preserve favourite plants or newly-set-out trees from the effect of drought; but very little beyond this. "Those who imagine," says the editor of the *Working Farmer*, "they find good results from spreading of manure on the surface, and leaving it for days, weeks, or months before it is ploughed under, mistake the action of the litter or longer portions of the manure as a mulch, for the action of the manure on the soil." We so far differ from this and kindred opinions on the subject, that we think manuring on the surface, for ninety-nine farmers in a hundred, the best general method of application. We except all cases where the drill application of compost is found desirable, and garden and lot culture. Nor do we maintain that there is not a more perfect method of preserving and preparing all the elements of the manure heap, by its careful husbandry under sheds, an occasional treatment with diluted sulphuric acid, or some other "fixer," a cistern to catch the drainings, and a pump to pump them back upon the heap, and patience and perseverance and constant watchfulness. A more perfect method still is that of Mr. Mechi, who applies his manure only in a liquid state, and for this purpose has his farm traversed with iron pipes, to convey the fluid to the different fields. He says it pays in England, and it may be so, though his neighbours doubt it very much. But on a Virginia farm, we think sensible men would account the Sheriff of London stark mad, We maintain that this mode of manuring (viz., on the surface) is in itself so little inferior to the most perfect methods, that taking into consideration the circumstances of our farming popluation, the extent of surface and high price of labour. the attention, and time and management that the mass of farmers can give to this branch of their operations, it is for them the most economical and the best. *It will pay better.*

We ask now the reader's attention to the ammonia theory. That *ammonia* is the element of greatest value in stable manures, we do not question. That it is very volatile, flies off and escapes by exposure to the atmosphere, everybody knows. Upon these principles is based the recommendation to plough under, immediately, manures which yield ammonia, that the earth may absorb and preserve it. Now let it be distinctly borne in mind, that *fresh* manure of any sort does not contain this volatile ammonia, but only *nitrogen*, which is not volatile, out of which the ammonia is formed; and that ammonia is generated only as the nitrogen putrefies in the rotting manures. If the manure accumulates in the stable, the warmth and moisture of the daily additions soon bring on active fermentation, and the pungent ammonia which assails us is the result of the putrefaction thus caused. Until this process of rotting commences, ammonia is not formed, and the manure not liable to waste, and it ceases to be generated when the rotting is checked. Now, when we are ready to remove our manure-heaps in the spring, we find them usually rotting to some extent. Let us follow, and observe the whole process. It is taken up first, forkful by forkful, and pitched into the cart; the ammonia, of course, all the time seeking its freedom; it is hauled, reeking and smoking, a long distance perhaps, to the field; now it is dropped into small heaps, where it remains a week or so, until you are ready to plough the land. If you are ready, or when you are ready, these heaps are carefully spread out on the ground, the more perfectly the better, and then ploughed under—not immediately, even under the most careful management, but as soon as it can be done—with a delay, ordinarily, of an average of some hours. Now, with all this necessary opening and forking, and tossing and spreading, our impression is that the free ammonia is very much like the Frenchman's flea, which when he put his finger upon it wasn't there; the point of time when we are ready to lay hold of it, is just when we may as well save ourselves the trouble: it is not there. But let it be borne in mind that the ammonia we have been dealing with, is that only which was generated in the rotting heap before its removal. When the heap was opened to the air, the process of rotting ceased, and ammonia was no longer formed. Supposing, then, this free ammonia is pretty well gone, at any rate we have the remainder of the manure, with its unchanged nitrogen (not ammonia) to deal with. Plough this under to the depth of eight inches, and for want of the proper temperature to cause its putrefaction, it may remain unchanged and unavailable until another ploughing shall bring it up again to the influence of heat and moisture, which will disengage the ammonia. It is a frequent experience, that we plough under deeply, for a spring crop, fresh stable manure, and receive no benefit from it whatever until it is brought up again to the surface, and the wheat crop following reaps the advantage.

But suppose, instead of making a week or two weeks' heavy labour of hauling out manure in the spring, when the teams are at best not strong, and there is a press of hard work on hand, you get rid of this necessity of hauling cut and ploughing under simultaneously, and hauling at your convenience, you throw the manure upon the surface of the grass field, what is the result? At the worst, as we have shown above, there is equal loss of the *free ammonia* when the manure is ploughed under. In both cases, that is about all gone, before it can be with certainty taken possession of, by any process. The mass remaining on the surface, however, the work of putrefaction, which made the free ammonia, and which was stopped by

the opening and exposure of the heaps, is now recommenced and very slowly carried on by the warmth and moisture at the surface. The ammonia thus formed is absorbed by the litter above it, and washed down by every shower into contact, and combines chemically with the humus at the surface, or with the soil itself. But bear in mind, that when these frequent removals are made, we never find the heaps in such a state of putrefaction as when we postpone to some one allotted time, and therefore never have so much free ammonia to deal with. A very large proportion of the manure never begins to rot before it is removed. By this plan, moreover, we take favourable opportunities for hauling, and may carry out much of the manure in damp or moderately rainy weather, when the showers will wash the ready-formed ammonia immediately into the soil.

We have thus undertaken to show that the practice of manuring on the surface is not inconsistent with admitted chemical principles, when properly applied; and we submit the explanation to the judgment of practical men, familiar with the processes of farm management.—American Farmer.

CALENDAR OF AGRICULTURE.

The sowing of all grain crops must now be finished as fast as possible, and also lucerne and flax-seed. Finish the preparation of grass meadow lands; sow vetches and grass seeds on wheat and barley tilths. The surface of wheat lands will be rough and stale; harrow it before sowing the grass seeds, and again after the seeds are sown, and roll with a heavy weight.

Prepare as quickly as possible the green crop lands, and towards the end of the month sow beet-root in drills well dunged, and twenty-eight inches apart; steep the seeds in weak solutions, and dry with quicklime. Plant potatoes in drills thirty inches apart, and well dunged with farm-yard manure in a half-putrescent state; use strong sets of tubers newly cut, very moist manure, and in a large quantity; cover the drills quickly, and roll them down. Before the land is drilled, spread pulverized lime evenly on the surface, in two hundred bushels to an acre, and harrow it immediately, or strew the cinders evenly over the ground, and the subsequent workings of the land will mix the lime, which will be powdered by the dampness of the soil. This mode requires an earlier application than the old way; but it must be more beneficial by reason of the damp and moist exhalations that will be evolved during the dissolution of the hot cinders of lime.

Early crops will now require both horse and hand-hoeing, as carrots, lucerne, wheat, beans, and peas.

Paring and burning of lands will now proceed vigorously. Burn the turfs moderately in a black scorched mass, as in that state carbonaceous matter most largely abounds. It is the best method yet known for bringing into cultivation all lands that contain much fibrous, inert, and ligneous matters.

Burn, for application by the drop drill, rough, earthy, and vegetable substances, found on road-sides and on ditch banks; also peat, and all combustible matters; the ashes will raise crops of turnips.

Rye, and watered meadows, winter vetches and barley, will now be ready for soiling cattle in the yards, and for being consumed on the ground by ewes and lambs. The food is best used by being cut and placed in racks, which are regularly moved over the ground. Fold the sheep nightly on the cleared space, allowing in the fold two square yards to each animal, and two nights in one place. All bare grounds and inferior grass lands may be much improved by the folding of sheep upon them.

The lambing season will now draw to a close. When beet-root and cabbages fail as food for the ewes, give oats, and bruised oilcake mixed, and with a portion of salt. Remove the strong lambs to the pasture fields.

Attend to the milch cows and to the suckling of calves; give the former an ample allowance of juicy food, natural or prepared; to the latter as much milk as the animals can drink. When begun to be weaned, at the end of sixteen weeks, give them in racks in the calf-pens young vetches, bruised cake, bean and barley meals boiled, and linseed jellies. Place a lump of chalk and rock salt to be licked; the latter substance will quicken the action of the digestive organs, and the former will correct the crude acidities of the stomach.

The last remaining fatting bullocks will be sold during this month; use oil-cake in finishing off the animals: the most backward in condition must go to grass.

The season of curing bacon being over, all pigs on hand must go on for summer stores, and come in for early winter fattening. The earliest fat lambs will now come in for sale.

During wet weather, carry all the dung from the cattle yard to the heaps in the fields, and litter the yards afresh for the summer soiling of cattle and horses.

Prepare by ploughing, harrowing, and rolling, the fallows for green crops, keeping most forward the portion to be sown with Swedish turnips next month. Plough clay lands for wheat fallows, and dung across the winter furrows with narrow slices.

SOAPSUDS.—In days that once were, the soapsuds went to the gutter as regularly as the washing-day was ended; and there are too many who allow the plan to be followed in the present day. All do not yet seem to have learned that a tub full of strong soapsuds is worth as much, as a fertilizer, as a wheelbarrow of good manure. Now every bucket of soapsuds should be thrown where it will not be lost. The garden is a good and convenient place in which to dispose of it; but the roots of grape-vines, young trees, or anything of the sort, will do as well.

B B

THE AGRICULTURE OF INDIA.

Removing my camp-stool to the opening of my little hill tent, I looked out into the fields, where I saw some men ploughing. For the first time, during my travels, I was struck with the appearance of the instrument which the natives use for tilling the soil; an instrument which, in fact, closely resembles that used by the Romans, according to the directions laid down in the Georgics:

"Curvi formam adcipit ulmus aratri," &c., &c.

—and, at first, I felt some surprise that an implement so apparently ill-fitted for the purpose for which it is designed, should answer all the requirements of the cultivator. The substitution of the English plough for this native hûr, has been several times projected by gentlemen who were zealous in the cause of agriculture, but without any success, or reasonable hope thereof; for when we consider the cheapness, and the great amount of labour always available, the general lightness of the soil, the inaptitude of the natives of India for great or continued physical exertion, the inferiority of the cattle, all of which are the marked characteristics of India, it would not only be undesirable, but impossible to introduce the English plough, generally, as an implement of husbandry — an implement requiring physical strength, manual dexterity, and a superior breed of cattle for draught. Rude and simple as the native hûr is, or as it may seem to the casual observer, cursorily viewing the operation of ploughing, it has still many good qualities which render it peculiarly suited to the genius of the Indian cultivator; and it is not in any immediate endeavour to improve it, or alter it, that any real benefit can be conferred on the cause of Indian agriculture. All the efforts, therefore, that have been made in that direction, have been time and trouble expended to no purpose. It has been said, that all improvement to be real, must be spontaneous, or take rise within itself; and it would seem to be more reasonable to improve such means and appliances as the natives use and understand, without running counter to the ideas, and shocking the prejudices, which they entertain, by endeavouring to compel their adoption of European modes of culture, which, however well suited to the land of their origin, have not the quality most necessary to their practicability, that of being comprehensible to the people of India. The true end of agriculture:

"With artful toil
To meliorate and tame the stubborn soil,
To give dissimilar yet fruitful lands
The grain, or herb, or plant that each demands,"

is best to be attained by aiding and assisting the development of those resources of the soil, which have already been made visible by the people themselves.

Here it is that the duty of the Government begins. The precariousness of the land tenure is one of the greatest impediments to the outlay of capital by the tenant in the improvement of the land; and as there is but little prospect of the removal of this objection, the Government should fulfil what would, were the case different, be the obvious plans of the landholder, in developing the resources of the soil. Irrigation and manure are the two great points most deserving of attention. On both points the resources of the country are incalculable; the advantages evident and immediate; both require system and an outlay of capital, which the zemindar (native landholder) is often unable, and oftener unwilling to adopt and incur—from want of confidence in the administration of the law, and the law itself. With the ryot, or cultivator, the case is very different. The law, or the administration thereof, affects him in a very slight degree, compared with the zemindar. The land tenure matters very little to him; his rights have been secured; he profits by the outlay of capital on the land. Risk, he has none. His advantage is immediate. But he does not possess the means of improvement in any way. He may build a well, dig a tank, or plant a grove to the memory of a departed ancestor, and, by so doing, enhance the value of the land to the zemindar; but he almost always ruins himself by the act, leaving his debts to be paid by his descendants, and the well, tank, or grove mortgaged to the banker, for the extra expenses incurred in its establishment! It behoves an enlightened government to do for the people and the country, what they are unable to do for themselves. An inquiry, properly set on foot, and undertaken by competent persons on the part of the Government, to investigate all particulars regarding the state of agriculture, would bring to light many facts, which, if made fitting use of, would not only greatly redound to the honour, but adduce greatly to the advantage and profit of the state. The information thus acquired, and not founded on the reports of native (government) collectors, police-officers, and peaons (messengers), but ascertained by the personal inspection of European officials, and from the opinions of the zemindars and cultivators themselves, would enable the Government to know and devise remedies to obviate the evils arising out of the gradual decline of the agricultural classes in our earliest occupied territories. It would show the Government many places where the expenditure of four or five thousand rupees (four or five hundred pounds) in the repairs or erection of a dam, for the obstruction of some rain-filled nullah (a wide and deep ditch), would yield a return nearly of equal amount, besides affording employment, and the means of livelihood to hundreds of persons. It would show where the opening of a road, or the building of a bridge, involving but a small expenditure, would give a new life to a part of the country hitherto forgotten, and render the inhabitants flourishing and happy, by throwing open to them a market for their produce—a market at present out of their reach. It would prove incontestably that the means of irrigation—the true water-power of India—has been even more neglected than the water-power of that (in comparison with the United States) sluggish colony, Canada. The initial step once taken—the march of improvement once fairly set on foot—private enterprise, duly encouraged, will follow in the wake of the Government; and capital once invested, land in India will become intrinsically valuable, and thus obtain the attention it merits. Agricultural improvement would induce lasting and increasing prosperity of the cultivating classes (the bulk of the population) and of the country itself.—*Household Words.*

AN AGRICULTURAL ODE.

BY WM. C. BRYANT.

Far back in ages
The plough with wreathes was crowned,
The hands of kings and sages
Entwined the chaplets round,
Till men of spoil
Disdained the toil
By which the world was nourished,
And blood and pillage were the soil
In which their laurels flourished.
Now the world her fault despairs—
The guilt that stains her story,
And weeps her crimes amid the cares
That form her earliest glory.

The throne shall crumble,
The diadem shall wane,
The tribes of earth shall humble
The pride of those who reign;
And war shall lay
His pomp away;
The fame that heroes cherish,
The glory earned in deadly fray
Shall fade, decay and perish.
Honour waits o'er all the earth,
Through endless generations,
The art that calls the harvest forth,
And feeds the expectant nations.

NORTON FARMERS' CLUB.

Report of the Judges (Mr. L. Furniss and Mr. J. J. Rowley) on the farms which competed for premiums in October last:—

"In examining the farms contesting for the premiums given by Messrs. Henry Rangeley, J. Dodson, and Wm. Staniforth, the judges had an agreeable and pleasing, yet difficult duty to perform. They had pleasure in witnessing the industrial efforts to cultivate and improve the soil of a district generally tenacious and frequently hilly; and in a sharp contest, they felt a difficulty in adjudicating according to the exact terms of the premiums offered. Having this difficulty before them—where the merits of each are so nearly balanced—it seems only reasonable and fair that the several competitors should have some mark of distinction to show a degree of merit, so that, if one competitor should win (to use a sporting phrase) by half a neck, the judges might have the privilege of placing the second and third in the race. For the reasons above stated, we recommended this arrangement to Mr. Rangeley, who generously consented to give us a discretionary power in awarding his premium of £5 to be equally divided between the several competitors—Mr. John Plant, of Birley; Mr. William West, of Windy House; and Mr. Thomas Parker, of Bowshow.

"We commenced the inspection of these farms on Tuesday, the 13th day of October, 1857. There had been a similar inspection in the previous year, and the system of cropping and general husbandry on these farms having been already described and published, it does not appear necessary on the present occasion again to notice it. But we have much pleasure in recording our entire satisfaction in the cultivation of these farms, as adapted to a *locale* immediately surrounding Sheffield, and not having any analogy to the cultivation of farms situate in a district strictly rural. Hence the difficulty of prescribed rules of husbandry and the laying down of a code and system of cropping, which ought to vary and will vary according to circumstances and situations. Climate and soils will have their effect; the quantity of rain falling, the proximity to mountains and towns, all exert an influence on cultivation, and give a wide scope for judgment in determining the course of husbandry to be followed. We are witnesses to these important elements in the cultivation of land, and hope we may say without vanity that, having had some experience in these matters, we are privileged to make any remark of praise or censure. Indeed, it may be expected that we should, in our perigrinations through the district, cast a farmer's eye, with furtive glance, over hedges and across the stubbles, where grow the stately thistle, the hardy couch grass, and the umbrageous dock—giving unmistakable evidence that in the 19th century these upas trees are cultivated in the parish of Norton, and at an easy distance from the metropolis of Hallamshire. But the cultivation of these plants is not the rule, it is the exception; and if there be much to condemn, there is more to commend and applaud. Still they are cultivated; their seeds are sown by inattention and neglect, and by the ignorance of natural laws bearing on good husbandry. In truth, the growth of these plants on the farm may be aptly stated as a disease of the skin, which, as in men and animals, affects the whole body corporate; the best remedy for which is cleanliness, and the application of purgatives, as administered by Dr. Bentall and others celebrated at the present day for the cure and eradication of cutaneous poison plants. It is not, however, the plants which are grown, to which we desire to call attention; it is the plants which are not grown, but which ought to be grown. There is a similarity in leafy appearance between the dock and the mangold. In the language of the ancient writer, we 'cleave to one, and despise the other.' The couch grasses and Italian grasses are similar in genera, but their effects are dissimilar and wide as the poles asunder. Like homœopathic treatment, as propounded by Dr. Hahnemann, a very small dose of couch grass will drive out Italian grass, and establish a cutaneous disease, that we imagine will run speedily over a hedge, across a turnpike road, or even a canal; such are its powers of contagion, or infection, or both. The thistles may be a stately plant—it is a Scottish emblem—but to our notion, we say, as appointed judges, it is the monkshood of Norton husbandry. And we do most earnestly recommend the club to abandon the growth of these exhausting plants, and substitute instead some of the genus colewort, such as the branching rape, the Scotch kale, and last but not least, the cow cabbage. We admire the plants we have mentioned, but we saw few or none. Some attempts to grow them were visible, but like 'angels' visits,' they were 'few and far between.' From Windy House to the Lees, from Birley to Bowshaw, these useful esculents were rare, and might really be looked on as exotics, and supposed to require a glass-house to grow them. No such thing; we tell you that, like the daisy, they blossom anywhere and everywhere, We tell you, wherever the dock will grow, so will the mangold; and it is a great fact that the rape and the thistle will grow on the same soil, but not at the same time and place. If farmers wish to grow thistles, they ought to be in rotation; and part of the course of husbandry pursued on the farm, and not at the same time and place as other root crops or legumes. Thistles and docks might be grown in alternate rows with mangolds or colewort; but we do not recommend it; and unless it could be proved that this course would suit the balance sheet when stock is taken, we advise the club not to patronise or follow it. Still, it is followed; and it may be gathered from these remarks, that in the inspection of the farms contesting for the prizes offered by the Norton Club and its members, we complain that these beef and mutton producing plants receive but little or no attention in the district. They are to the farmer 'the Hebrew, Greek, and Latin of the school-boy.' But when understood and cultivated, they are the classical as well as the practical and useful in husbandry. We have digressed, and must now leave the grumbling, to notice other things more agreeable in our report.

"In class 36, where the premiums are given by Messrs. Dodson and Staniforth, for the best cultivated farms under 50 acres, we found three competitors—Mr. Hutton, of Ridgeway; Mr. Joseph Wragg, of Norton Lees; and Mr. George Rogers, of Lightwood. These farms, considering the limited time we had at our disposal, were carefully inspected, with a view to do justice to the gentlemen who had generously offered the premiums.

"On inspection of Mr. Hutton's farm of 28 acres, we found the land in a good state of cultivation; the farmery well arranged and in good order; the whole of a character creditable to the occupier.

"Next in succession in this class of farms we visited Mr. J. Wragg's farm, of Norton Lees, consisting of 32½ acres. Judging from the produce of this farm, the crops must have been very good; the root crops exceedingly clean and well arranged, having been highly manured, as evidenced by the weight of the crops. The whole of the land on this farm is in a high state of cultivation, the fences in a very creditable condition, and present a neat appearance; stock numerous and good; farming premises very orderly, and every department of the farm showing evident signs of presevering industry.

"Mr. George Rogers' farm, at Lightwood, consisting of 30 acres (20 occupied since March, 1856). On inspection of this farm we were very much pleased with the substantial character of the improvements effected by the occupier in so short a time. A considerable sum must have been expended. 15 acres effectually drained with pipe, tile, and stone. Depth of drain, 30 to 33 inches, five yards apart. A considerable length of old, neglected hedges plashed, the sides grubbed close up to the fence. The root crops highly creditable, being very good and well arranged; additional buildings put up at the farmery; the house renovated and much improved; new gates introduced. The whole of the operations carried out in a most determined and skilful manner. Having seen this farm when first entered on by its present occupant, it being then in a most dilapidated condition, great praise is due to Mr. Rogers for the many and great improvements made in so short a time.

"To conclude, we can only add one remark, and that will apply to all the farms in this class. We saw proofs of good husbandry, neatness, and cleanliness throughout. Capital and

labour had been judiciously expended; and when the contest was sharp, and on nearly equal terms, we did not quite agree in our views and opinions. The matter in dispute was left to the arbitration of one of the competitors, who generously decided against himself, that Mr. Wragg should be No. 1, and Mr. Rogers No. 2.

"In offering the above report and animadversions on what we saw and examined, we trust that they will be received in the same spirit in which the men of the Norton Club always receive good intentions."

SUFFOLK LENT ASSIZES.

BREACH OF CONTRACT.

GARRETT *v.* WOOLNOUGH.

This was a Special Jury case.

Serjeant Wells and Mr. O'Malley for the plaintiff, and Mr. Couch for the defendant.

The action was brought for breach of contract.

Mr. O'Malley having opened the case,

Mr. Garrett deposed: I am the senior partner of the firm of Garrett and Sons, Leiston Works. At first I carried it on myself, and then took my sons in. The defendant was formerly in my father's service, and continued with me down to 1855. He occupied the post of foreman over a small portion of the manufactory and salesman up to April, 1854. He had a salary of £150 per year and a house. In November or December, 1853, the defendant reminded me that the agreement terminated, and that he wanted an advance of salary. I agreed to advance him £50 per year. He afterwards wished that the £50 should be paid for five years in advance, to which I agreed, and an agreement was drawn up. He suggested that it should be binding for ten years, so that at the end of five years I should pay him another £250. The £250 was paid on the 6th of April. On the 31st of July, 1855, the smith's foreman showed me some ironwork which Woolnough had sent back, and on the 1st of August, as I was standing at the counting-room door, the defendant came up to me, and in abusive language said he would not be humbugged any longer; he was going away. I turned round and said, "What's the matter?" He was in a passion, and I told him to go home and consider the matter. I said, "There is an agreement between us, you had better look to that." On the following day I sent for defendant, and he came to my counting-house, and I asked him if he had considered what he said the day before, and he said "Yes, he was going." The 31st of July was a critical period, being after the Royal Agricultural Society's Show, and we had many orders, particularly in defendant's department. After some conversation, I told him he must pay me back the proportion of the bonus; but he laughed, and patted his hand on his pocket, and said he should keep it. I suggested he should go and ask advice as to that of some man of business. The day after he came again, and said he had been for advice and found he must return the money; and he would pay it me if I would give a receipt in full of all demands and cancel the agreement. I refused to take the money on these terms. (The receipt which Mr. Garrett proposed reserved to himself any rights he might derive under the agreement.) He would not pay the money on this receipt, and went away. The defendant had a son-in-law named Sudbrook in the smiths' department. The defendant had been of great use to me in the sale department, and after he left me my sons were obliged to attend to the getting proper foremen into Woolnough's department instead of the general supervision. We tried to get persons to suit us as salesmen, but could not, and we lost very much commercially. I employ 600 or 700 hands, 60 or 70 of whom were under the defendant's supervision. I would rather not state the loss, but I would have gladly given another man a larger salary as a user and seller of implements.

Cross-examined.—I don't think we received any damage from his leaving us as foreman. We made better implements without him than we ever could have done with him, but we had to neglect the selling department, and lost more by that. It is very difficult to replace a foreman to sell implements and show them to the best advantage. He had been with me many years as my assistant, but when my health failed I sent him. Other men used to go with me to show particular implements. On the 2nd of August he did not ask me to allow him to remain. I did not say that when he left the room he would no longer be my servant. After we had made our arrangements I understood from my son that he was desirous of remaining. On the 4th of August I wrote a letter, in consequence of an application from him, stating that "W. Woolnough knew R. Garrett's views, and when he was prepared to fall in with their views R. G. would see him." Had not made any arrangements for substituting him as a seller of implements, but as a foreman. On the 4th of August he wished to leave, but in consequence of his behaviour I could not allow it. I did try to make an arrangement to keep him as salesman, but failed. On the 10th of August defendant received a letter from my son. (The letter stated he could only be received back on R. Garrett's terms.) The terms were that he should show the implements and buy timber, and should have £50 a year for buying timber and 10s. a day when he attended market. I thought I should make his income as much as formerly. Mr. Neeve came to me and asked me to take him back under the old contract. We appointed three men the same day to take Woolnough's place as foreman. They were paid as common workmen before, but their wages were advanced £1 and 10s. a week.

Re-examined: I received his letter on the 31st of July, but did not proceed to make arrangements to fill his place until the next day. I could not put the defendant as foreman over a number of men after he had abused me before the men without any cause whatever.

Mr. E. Cottingham, brother-in-law of the plaintiff, corroborated the previous witness as to the conversations which took place between him and defendant on the 1st and 2nd of August.

Cross-examined: Mr. Garrett never said, "When you leave this room you are my servant no longer." I advised Mr. Garrett to give defendant the agreement and settle, but he would not. I also advised the defendant to settle it.

James Kirrage deposed: I was in plaintiff's service in July, and Woolnough said to me Ludbrook was the man to be put foreman over the smiths' department. On the evening of the 2nd of August the defendant came to my house and said, "I have left Mr. Garrett's service, that's certain, and will stand no more of their humbug." I asked him not to be too fast.

Mr. Taylor deposed: I have been with Mr. Garrett thirty years. On the 31st of July Woolnough came to me to settle with him for his expenses to Carlisle. I refused; and he said he was off, he would have no more of it.

Cross-examined: I refused to settle the expenses, as I heard there had been some unpleasantness between him and Mr. Garrett. As the firm had advanced money to him I did not know whether he had money to pay or receive.

This being the plaintiff's case,

Mr. Couch contended that no breach of covenant had been proved.

His Lordship held that the defendant had not left the plaintiff's service; but was ready to perform the agreement, only he would not let him.

Mr. O'Malley objected and his Lordship reserved the point.

Mr. Couch was addressing the jury, when his Lordship suggested that a juror should be withdrawn on the defendant paying the proportion of the bonus £184, Mr. Garrett promising if any balance was due to the defendant it should be deducted from £184.

Mr. Couch applied for time for payment; but on Mr. O'Malley objecting, it was agreed that the money should be paid under a rule of court in a month.

Mr. O'Malley stated that there were three other actions pending for infringement of patent, and his client was willing to refer the cases to any three respectable men.

Mr. Couch declined to do so.

SIMPLE TEST FOR GUANO.—A bushel of guano, if pure, weighs almost exactly 70 lbs.; if adulterated with light substances (which is rarely the case), it will, of course, weigh less. If clay, marl, sand, &c., have been used, the weight will be materially increased, and, so far as this test applies, gross adulterations will be easily detected.—*Cameron's Chemistry of Agriculture.*

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR MARCH.

Since we last wrote, the weather in nearly all parts of the United Kingdom has been very favourable for out-door farm labour, in which, consequently, great progress has been made. Much of the light wheats, and most of the spring corn, have now been sown even in our backward counties, and the land has been everywhere in fine condition for the reception of the seed furrow. So far, therefore, everything is in a satisfactory state; but when we consider the wheat trade, the continuous decline in prices, and the future prospects of the growers, there is reason to anticipate a state of things—as respects wheat in particular—almost without a parallel. The effects of the late severe panic in the commercial world—a panic that has led to a decrease in our aggregate shipments during the first two months of the present year, compared with last season, of nearly *four millions* sterling—have, to some extent, produced a decline in the consumption; there is literally no speculation going on, either in home or foreign produce, notwithstanding that money is unusually abundant and cheap; and great anxiety continues to be shown by the holders of foreign grain to sell at almost any price. The result of the last year's wheat harvest in this country shows an enormous yield, and an unusually large quantity on hand, both in barn and stack. Throughout France the produce seems to be equally large; and the same state of things prevails in the United States. The consequence is that we have had all sellers and very few buyers, except for immediate consumption, and forced sales of grain have continued, to the prejudice of the value of home-grown qualities. Again, in order to compete with French flour—which may be had as low as 34s. per 280 lbs., free on board, at Nantes—the town millers have reduced their top price to 40s., and country marks have fallen in an equal proportion. The value of wheat has, too, declined fully 4s. per quarter, and the question generally asked is—When will the downward movement cease? We can scarcely assume that wheat can be much lower than it now is, because it would be better for the wealthy growers to withhold supplies altogether, and take the chance of future markets, than sell at present quotations; but, at the same time, it is very evident that any advance cannot be anticipated at present. The last official averages show a fall in the quotations, compared with the same time last year, of about 12s. per quarter, and, in the present tone of the trade, that difference seems likely to increase than diminish. From France, the north of Europe, and from the United States, we are threatened with heavy importations in the face of great abundance at home, and there is not the slightest appearance of speculative investments.

The want of speculation has compelled the foreign houses to sell on their own account; consequently there has been no accumulation of supply in warehouse. However, there is no question but that the downward movement must have a limit, and that ordinary prudence on the part of our farmers, and of shippers generally, will have its accustomed influence upon the demand.

The barley trade has continued healthy, and prices have ruled steady. Oats, beans, and peas have likewise commanded extreme, to rather advanced, rates; and these articles are likely to sell well, and at full quotations, during the remainder of the season.

A further advance, owing to their scarcity, has taken place in the value of the best potatoes. We, however, continue to receive large supplies from the Continent, in fair condition, and which have changed hands at from 80s. to 105s. per ton. Evidently, the extent of our growth last year—though we admit that a large portion of it has turned out unfit for human consumption—has been much under-rated, as, even now, the supplies on hand are extensive.

The result of the last Colonial sales is quite as satisfactory as could have been anticipated, considering the dulness of trade in our manufacturing districts. Fine wools sold at 1d. to 1½d. per pound more money; but inferior qualities went lower. The English wool trade has been in a state of great depression, and the fall in prices during the last six months has been fully forty per cent. This decline arises, in some measure, from the almost total absence of the usual Continental orders. This year's clip is turning out unusually large, even in districts not generally considered "crack" ones. Advices from Australia bring great heaviness in the wool trade, and a fall of from 1d. to 1½d. per pound in the quotations.

In the value of hay and straw very few changes have taken place. Meadow hay has realised £2 10s. to £4 4s.; clover do., £3 10s. to £5; and straw, £1 5s. to £1 10s. per load.

Throughout Scotland farming operations have progressed steadily, and the wheat trade has ruled heavy, at drooping currencies. Fat stock has likewise fallen in value.

In Ireland, the transactions in all kinds of produce have fallen off, and prices have ruled in favour of buyers. The shipments of grain to England have been very small for the time of year.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that only moderate supplies of fat stock have been on offer in the Metropolitan Market, the greatest heaviness has prevailed in the trade generally, and a serious decline has taken place in the quotations. The continuous fall in prices has led to the opinion in various quarters that the consumption of food *in London* is rapidly falling off. Such, however, is not the fact, and the cause of depression in the currencies may be easily traced. That an unusually small amount of butchers' meat is now being consumed in the manufacturing districts, is obvious from the enormous supplies which have reached London by railway, and which, in a general way, would have been sent to Manchester, Birmingham, &c. These supplies—which, in some weeks, have amounted to *twenty thousand* carcasses—have been overwhelming; so large, indeed, have they proved, that the greatest difficulty has been experienced in effecting sales on any terms. Had they been only moderately extensive, seeing that the consumption of meat in London is still large, prices would not have run down to their present low point, and great losses, on the part of those who bought store stock at high values, would have been prevented. On the part of the foreigner there has been very little competition, as the surplus produce of both Holland and Germany is still directed to France. In February there were imported into that country 19,119 oxen and sheep, against 23,513 in the corresponding month in 1857, and 23,050 in 1856. It is true that these figures show a slight falling-off when compared with the two previous years; yet they prove that the production of live stock in France is considerably less than the consumption. Our dependence upon the foreigner, as will be seen by our statistical details, is now reduced to a nominal amount, and the reduction in our importations shows a steady onward progress in our production, both as regards number, weight, and condition. The high prices prevailing in this country up to a recent period have, no doubt, operated as a stimulus to production; and our impression is that there is now more stock, both in England and Scotland, than has been known for many years past. Perhaps, however, our remarks may be more strictly applied to beasts, the breeds of which are now undergoing changes of great importance. In Norfolk the shorthorns have been more generally introduced, not only as a separate breed, but they have been mixed with Scots, until the pure breeds of the latter have become much less numerous than formerly; in point of fact, the Scots in Norfolk are not now kept up, as formerly, by direct arrivals from Scotland, owing to the Scotch breeders keeping their store animals at home, and the shorthorns have been more generally introduced into that and the adjoining counties as fresh blood; hence,

of late years, noble-looking and heavy Scots, to all appearance, have arrived from Norfolk; whereas it has been recently discovered that they are crosses with the shorthorns. The supplies of really *pure* Scots now derived from Scotland for the Metropolitan Market are gradually falling off: the size of the stock is increasing, and yet no fault can be found with the quality of the meat. Scotland, therefore, arising from the steady increase in the growth of the root crops, is now furnishing more meat than at any given period during the present century. To some extent, these remarks may be applied to Ireland. The old Irish breed, generally a slow feeder and a large consumer, is making way for English blood. Crosses are now the general fashion, and we are, consequently, enabled to draw stock from most of the Irish ports during each month of the year. We will not now stop to argue the question whether this comparative neglect of pure blood will eventually reduce our supplies of food; but, to all appearances, the system up to this point has worked well, and greatly increased the amount of consumable food.

Compared with the corresponding period last year, prices, almost generally, show a fall of nearly 1s. per 8 lbs., but we see no reason to apprehend any further important decline. True, we have bread at very low figure—viz., from 4½d. to 7¼d. per 4 lbs. loaf; but, on the other hand, potatoes of good and sound quality are very scarce and dear. It frequently happens, however, that whilst the commerce of the country is in an active state, and whilst the price of wheat is low and drooping—such being the case at this moment—the effect upon the value of other kinds of food is important; and it is just possible, even though the trade of the country may revive, that both beasts and sheep will be selling at rather low quotations during the next two or three months, unless there is a considerable falling off in the arrivals of dead meat per railway.

In nearly the whole of our grazing districts the health of the stock has continued good, and very few losses have been sustained by disease. The lambing season has passed off remarkably well, the weather having been highly favourable for it, and the fall has been larger and stronger than for many years past.

The following return shows the importations of live stock into the United Kingdom during the past month:—

Beasts	666	head.
Sheep	318	,,
Calves	527	,,
Total	1,511	,,
Same time in 1857	5,419	,,
,, 1856	1,842	,,
,, 1855	2,103	,,
,, 1854	8,409	,,
,, 1853	10,884	,,
,, 1852	6,747	,,
,, 1851	8,381	,,
,, 1850	6,004	,,

The above comparison shows that last month we imported a smaller amount of supply than during the last eight years; but this falling-off has been *more* than made good by increased production at home—a fact which appears to be worthy of special remark.

The total supplies of stock shown in the London market, derived from all sources, have been as under:—

Beasts	17,821	head.
Cows	476	,,
Sheep and lambs	74,410	,,
Calves	704	,,
Pigs	1,915	,,

COMPARISON OF SUPPLIES.

March.	Beasts.	Cows.	Sheep.	Calves.	Pigs.
1857....	17,345	490	74,880	1,118	2,230
1856....	22,623	470	100,700	797	2,140
1855....	18,644	380	86,790	835	2,765
1854....	20,533	532	93,060	1,091	2,780
1853....	19,228	360	85,680	1,614	2,780

The few lambs on offer have sold slowly, at from 6s. to, in some instances, 7s. per 8 lbs.; and the supplies of sheep out of the wool, have rapidly increased. The general quotations have ruled thus:—

	s. d.	s. d.
Beef,	from 2 10	to 4 6
Mutton	3 0	— 5 2
Lamb	6 0	— 7 0
Veal	4 0	— 5 2
Pork	3 0	— 4 4

COMPARISON OF PRICES.

	March, 1855.		March, 1856.		March, 1857.	
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
Beef, from	3 4	to 5 0	.. 2 10	to 4 10	.. 3 4	to 5 0
Mutton	.. 3 4	— 5 2	.. 3 2	— 5 2	.. 4 2	— 6 0
Veal	.... 3 10	— 5 4	.. 4 10	— 6 0	.. 4 4	— 5 8
Pork	.... 3 2	— 5 4	.. 3 4	— 4 8	.. 3 6	— 5 2

The month's arrivals of beasts from Norfolk, Suffolk, Essex, and Cambridgeshire have amounted to about 10,610 Scots and shorthorns; from other parts of England, 2,600 of various breeds; from Scotland, 1,720 Scots and crosses; and from Ireland, 1,350 oxen and heifers.

Immense supplies of each kind of meat have been on offer in Newgate and Leadenhall. The trade generally has ruled heavy in the extreme, and a considerable fall has taken place in the quotations. Beef has sold at from 2s. 10d. to 4s.; mutton, 3s. 10d. to 4s. 4d.; lamb, 4s. 8d. to 6s.; veal, 3s. 8d. to 4s. 8d.; and pork, 3s. to 4s. 4d. per 8 lbs. by the carcase.

The City authorities—under, we presume, the impression that a change of day will improve the trade of the Metropolitan Market towards the close of the week—have determined to change the day of holding the market from Fridays to Thursdays. The continued falling-off in the supplies of stock, when compared with Smithfield, and the enormous sums lavished upon the new market, have rendered it necessary to double the tolls; and now, in order to attract additional supplies and more buyers, a change in the day is considered necessary. The authorities should bear in mind that double tolls will have the effect of reducing the supplies shown—that ever since the market has been removed a smaller number of stock, taken in the aggregate, has been brought forward—and that any change in the day ought to be taken into consideration by purely practical men. We are told that the butchers require more time to get their stock home and slaughter it for Saturday's business; but surely every man at all acquainted with the trade must be aware that the butcher—more especially as he has now to travel several miles of additional ground—finds it necessary to visit, *in one day*, not only the Metropolitan (or live) market, but also Newgate and Leadenhall. Now, in hot weather, this would be impossible; and it is quite clear to us that the change—as was the case many years since—will prove a complete failure, and that eventually only one market day will be held in each week, because unquestionably the butcher's interest must be consulted, or he will turn his attention to local markets, which are now rapidly increasing in importance.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

CARMARTHENSHIRE FAIRS.—Cattle fairs have been held at Haverfordwest on the 20th, at Narbeth on the 22nd, and at Newcastle Emlyn and Cross Inn on the 23rd of this month. The show of store beasts was considerably under the average of former years, and the dealers purchased very sparingly at from 12 to 15 per cent. lower than last year's prices. Fat cows sold readily at from 5d. to 6½d. per lb., according to quality, sinking the offal. The few cows with calves shown, sold at highly remunerating prices. Horses and colts were scarce, and sold at very high rates. The small number of bacon pigs and porkers sold at from 5½d. to 6d. per lb. dead weight. A fair number of store pigs were on offer; those sold rather sluggishly at lower prices.

DERBY FAIR.—The horse fair was very small, and with few exceptions the animals exhibited were of a middling character. In horned cattle and sheep very little business was

done. The attendance was unusually scanty, and the fair is described as being upon the whole "very poor."

DURHAM FAIR. — Buyers were numerous. Colonel Teasdale attended as a purchaser on behalf of the Government. Superior horses sold at about 100 guineas; army horses, £25 to £30, and in some few instances, £35; best cart horses, £30 to £35 per head; commoner animals were a drug. Prices are 10 to 15 per cent. lower than last year. Dealers and farmers state that prices are yet likely to fall considerably.

EAST RETFORD FAIR.—There was a good attendance of buyers and sellers. There was a very large show of agricultural and draught horses of a superior description. There were but few hacks shown, and but little business done in either description of these animals. Prices ruled, for really useful sorts of draughts, from £33 to £40; hacks, £20 to £30. As usual there were plenty of "offal" horses on sale. There was a large supply of cattle, but very little fat stock on sale. Drapes and steers readily sold from £9 to £14, according to size and quality. Milkers and store beasts went off sluggish. There were but few calves. Beef sold at 8s. per stone, and mutton at 6½d. per lb. Hogs realized 37s. fully. Few sheep were penned.

HELSTON FAIR.—Purchasers were not willing to give so high prices as ruled for some time past. Towards the close of the fair, however, a good amount of business was done. A fine lot of bullocks, five in number, reared by Mr. John Tyacke, of Merther, was sold by auction, and realized good prices.

HEXHAM FAIR.—A moderately light show of cattle, which met a brisk demand at good prices, excepting milk cows, which sold slowly at drooping prices. Horses a very good show; demand slack, prices lower, and many left unsold. Pigs a numerous show, at lower rates, and part left unsold.

HORNCASTLE HOG SHOW AND FAIR—Was the largest that has ever been known, the recent favourable alteration in the weather having brought sellers of stock into the market in large numbers, in expectation of a rise in prices. Both beasts and sheep partook of the upward tendency, and although the market was rather lower than was anticipated, the stock exhibited was gradually disposed of. There was a strong interest excited in the competition for the silver cup, given by Mr. Stanhope to the exhibitor of the best pen of hehogs; the competitors being Mr. Parker, of Walmsgate, Mr. Jos. Walter, of Edlington, and Mr. Jos. Davey, of Fulletby. Mr. Parker was again fortunate enough to bear off the prize, and obtain a companion to the cup he won last year. The judges were Jos. R. Kirkham, Esq., Andleby, Mr. Harwood Mackinder, Langton, and Mr. Mayfield, Dogdyke.

ILSLEY FORTNIGHTLY MARKET.—There was about an average supply, and a fair attendance of dealers. The sheep this season are in good condition, and handled remarkably well. The trade was dull, but eventually nearly the whole was disposed of at about 1s. to 2s. per head reduction from that day fortnight.

LEOMINSTER FAIR was well supplied with most descriptions of stock, but the trade ruled dull except for steers and good barren cows, and those were in demand at high rates. Cows and calves met with customers and remunerative prices. Beef averaged 6½d.; and wether mutton, in the wool, 7½d. per lb. Pigs were low. Really good horses in demand at high rates; inferior animals lower.

MUIR OF ORD FAIR.—3,689 sheep, chiefly Cheviot hoggs, were for sale. Last year the number on the same day was 3,690. On this occasion the sheep were in fair condition, but not equal to last year; and in estimating the fall of prices, some allowance must be made for this fact. The want of keep throughout the country, and the depreciation in prices, told heavily on the market. Until about three o'clock only two transactions were reported; these were two lots, each of from 300 to 400 Cheviot wether hoggs, in good condition and well-bred, which were sold at a guinea a-head—Mr. Scobie, Lochinver, and Mr. Clarke, Eribole, being the purchasers. They were reported to be the best lots on the ground. After three o'clock Mr. Scobie gave the market a little activity by purchasing several lots of hoggs, at from 18s. to 20s., which were counted cheap at the money, and sold from want of keep at home. Mr. Fraser, Mauld, bought a lot of Cheviot hoggs from Mr. Ross, Fairburn, at 14s.; and another lot at the same figure. Mr. Sim, Scotsburn, sold a lot of black-faced hoggs at 13s. A fine lot of half-bred wethers, belonging to Mr. Macleanan, Tomich, were intercepted on their way to the Inverness steamer, by which they were to be sent to Edinburgh, and were bought by Mr. Jackson at 35s. a-head. Mr. Mackay, Cape Wrath, bought Cheviot wether hoggs at 19s; Mr. Mackenzie, Balnabeen, sold the Mulchaich shot Cheviot wether hoggs at £16 per clad score. The market on Thursday was duller than on Wednesday, and at a late hour little or nothing had been done. Forty cattle were on the ground, fifty horses, and seventy-six pigs, besides a large portion of the sheep exposed on the previous day. A good many horses changed hands, and most of the pigs; but, so far as we could learn, there was not an offer made for any of the lots of cattle, and nothing further was done in sheep. Horses were greatly down from last year, and pigs were selling at something like 20 per cent. less than at the corresponding market of 1857.

NEWARK FAIR.—There was a moderate supply of store beasts, which sold as well as was expected, at prices considerably below those realized this time last year. There was a good supply also of milking cows, but prices were not so high as at previous markets. We had a good show of sheep, which sold off much lower than last year; hogs fetched about £2 each. Not many lambs were shown at the stock market on Tuesday; the show of sheep was good. Prices were 6d. per lb. out of wool, and 7d. in wool. Beef realized 7s. to 7s. 6d. per stone.

ROSS FAIR was not so well attended as it generally has been. Beef fetched 7d. per lb., mutton 6½d. There were very few horses offered, and the sales were generally dull.

UPTON FAIR.—The supply of stock was larger than usual. Useful cows and calves sold at from £13 to £14 a-piece; barrens about £11 or £12 each; wether sheep averaged from 30s. to 40s. a-head. Store pigs were numerous, and were disposed of at a considerable reduction in price from last year's value.

WREXHAM FAIR was exceedingly well attended by business men, but the tendency of prices for all kinds of stock, with the exception of sheep, was downwards, and in consequence not a very large amount of business was done. The show of fat stock was good, but barrens fetched the best prices comparatively. Sheep were scanty, both fat and store, and prices were firm. Of horses there was a larger show, especially of cart-horses, amongst which there were many fine animals, the prices ranging from £30 to £50. Pigs were plentiful, and cheaper than ever known in Wrexham.

YORK FAIR.—Very few lean beasts were shown, and business trifling. A moderate supply of horses had slow demand, at rates much below last Palmsun fair.

IRISH FAIRS.—BALLINAKILL: There was a good average display of stock. Prices ruled pretty much as during the past month, and good store stock were in demand. Store pigs sold a shade lower than previously. At ATHLONE FAIR there was large supply of prime cattle, for which there was little demand, in consequence of the absence of Leinster buyers. The supply of pigs was very large, but the demand was slow, and prices were very considerably down from the January fair. CARLOW: There was a good supply of stock, principally stores; but there was a disinclination on the part of graziers to purchase, unless cattle of good quality. Fat stock manifested a downward tendency — some prime lots brought good prices. Mr. Joseph Fishbourne sold two three-year-old stall-fed heifers for £17 per head. Major M'Mahon received for a lot of fat heifers £13 5s. per head. A large lot of stores, two and a half years old, were sold by Mr. B. B. Feltus to P. Maher at £10 per head. Beef may in general be quoted from 50s. to 55s. per cwt. for prime. Strippers and dry cows were numerous, and those of a good quality sold well; inferior classes were not much in request, prices ranged from £13 to £16. Mr. Browne, of Ballyraggan, county Kildare, sold a lot of three-year-olds for £10 12s. 6d. per head; and Mr. Browne, of Corbally, a lot of three-year-old bullocks, at £11 17s 6d. The sheep fair was thinly supplied, but some lots of excellent quality were exhibited. Mr. Thomas Dowse sold a prime lot (fat) at £3 10s., the top price; Mr. Peter Salter, a lot of wethers at £2 7s. per head. The average price of hoggets was from 35s. to 42s. Store pigs from 20s. to 25s., bonhams 7s. to 12s. per couple.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

The mouth of March has exhibited extraordinary differences of temperature. The first fortnight was a continuation of the sternness with which February closed; but immediately afterwards a brilliant spring-time commenced, with a warmth occasionally oppressive, and an almost entire absence of rain. Field-work was immediately resumed, and the sowing of Lent corn, which had been interrupted by the severe frost, has proceeded most favourably. Whatever damage was done to the wheat and other autumn-sown corn by the cutting winds must soon be apparent, but as respects the principal grain very little harm has been yet reported beyond what might have been expected on exposed and light lands, from the want of a snow covering. The dryness of the whole season, and the general appearance of the plants, are favourable to future prospects. The uncertainty of politics at the outset of the month seemed a check upon business, but the renewed assurances of peace, followed by the most propitious weather, and a liberty to export wheat in the Papal States, have combined, towards the month's close, to somewhat reduce prices, and the value in the London market has receded about 4s. per qr. On all hands it is allowed that good stocks exist throughout the country; and if, with a steady importation from abroad, farmers show an anxiety to sell, and overdo the markets at a time when the spririt of speculation is entirely wanting, there can be but one result, viz., a still lower range than what is now obtaining. One thing is however certain, that the reduction in value greatly increases consumption; and the largest importations and lowest rates have invariably been followed by scarcity and dearness, and the safety of holding must be proportioned to the moderation of prices.

In the Baltic the season was commenced with empty garners, and the produce of 1857 in these quarters is consequently reported to be below an average; and should any drought occur this year in these fertile provinces, they may require an importation: while Spain continues in this position, and is likely to remain so till her new crop is gathered. Neither Odessa or the United States have yet shaped their course by the English markets, though doubtless supplies will come on thence for the chance of improvement here, but not at the rates suggested by interest or apprehension, for old wheat has become a scarcity both in the old world as well as the new one; and while it behoves us never to mistrust an overruling Providence, it is well to remember that the blade on the ground is not the sheaf in the barn. The importation from the Papal States is not permitted beyond the end of May, and should prices rise materially before then, would be suspended. In Southern Europe and Algeria the wheat crop at present looks well, but in the North some fears have been felt, as the consequence of the great changes and exposure.

The following were the recent quotations of wheat in different foreign ports:—At Paris the finest quality is quoted 41s., and Antwerp notes 42s. 9d. per qr. as a top price. Polish wheat at Amsterdam brought 56s. per qr. The best quality on the spot at Hamburgh was held at 45s. The rate at Stettin was 40s. 6d., and at Berlin 41s. 6d. Ghirka and Polish wheat at Odessa was still worth 43s. per qr. Low Saidi wheat at Alexandria had sold at 27s. 9d. Berdianski quality, at Leghorn, was held at 44s. per qr. At Alessandria, in Piedmont, top price was 41s. for soft wheat. Barcelona quotations were still as high as 52s. 8d. per qr. New York, by last accounts, was firmer; the price of good red there was 1 d. 25 c., equal to 43s. per qr.; Southern white 1 d. 30 c. to 1 d. 52½ c., equal to 44s. 8d. to 52s. per qr.

The foreign importations into United Kingdom for the two months ending February 28th, 1858, were 606,394 qrs. of wheat, and 613,860 cwt. of flour.

The first Monday commenced on a small supply of foreign wheat, and a moderate one of English; from the near counties, during the morning, the samples were but few. The weather was then extremely cold, and the condition being improved, it went off steadily at the prices of the previous week; there was also a fair retail demand for foreign. In the country there were but slight changes: Hull, Manchester, Birmingham, and Bristol were firm; Lincoln and Louth were 1s. dearer, but a few markets equally declined; Liverpool, being over-supplied with French wheat, was 2d. per 70 lbs. cheaper. Friday's market there underwent no farther change, and the London trade remained quiet to the week's end.

The second Monday was still less liberally supplied from abroad, and what arrived was chiefly from Antwerp; of our own growth, the quantity was moderate. The morning's supply from Kent was good, from Essex insignificant; the business done was effected slowly, but there was a pretty general clearance, at full prices; foreign samples being unchanged. No particular change took place in subsequent country markets: Leeds and Hull were firm, but Birmingham scarcely obtained former rates; Liverpool had but a thin attendance both on the Tuesday's and Friday's market, and no alteration of quotations was noted.

The third Monday had an increased supply of foreign, with rather more English; the near counties also during the morning sent up rather more samples, and the weather having completely changed, with some appearance of permanence, there was less disposition to buy on the part of millers. Early in the morning at the Kentish stands some choice parcels were quitted at quite as good prices, but it was afterwards difficult to place without a small concession. The foreign trade was heavy without change. Several of the country markets responded to the London reports by accepting a decline of 1s.,

among them were Birmingham, Wakefield, and Bristol, while Wolverhampton and Chelmsford quoted a fall of 1s. to 2s. No reports were cheerful, the majority merely indicating a heavy state of trade. French wheat was again rather cheaper at Liverpool on Tuesday, but Friday's report only noted a small attendance, and retail trade. London was then certainly tending to lower rates.

The fourth Monday occurring after a week's very fine weather, with fair supplies both English and foreign, did not require a large quantity from the near counties to make a heavy market, especially as there was a liberal arrival of American flour. Though Kent and Essex scarcely sent an average quantity, millers held off, and notwithstanding factors were willing to take a reduction of 2s. per qr., only a small portion was sold on these terms, an apprehension apparently prevailing that the breaking up of the frost would soon largely increase the arrivals from abroad. The foreign trade was in a state of stagnation, sales being only possible in retail at a similar decline. In the country about a similar decline took place: Hull, Lynn, St. Ives, Gainsbro', Birmingham, Wolverhampton, Manchester, and Bristol were all 1s. to 2s. lower, Louth giving way 2s. to 3s. per qr. Liverpool, on Tuesday, was 1d. per 70 lbs. cheaper, with a very small business; but Friday was dull, without change.

The fifth Monday had very short supplies from Kent and Essex, but an extreme dulness prevailed, and prices further receded 2s. per qr.

The arrivals into the port of London during the five weeks referred to were 24,580 qrs. English; 29,551 qrs. foreign; giving a weekly average of 10,826 qrs., and showing a decrease as compared with February, of 1,703 qrs. per week; the falling off being only in foreign qualities.

The flour trade has been in keeping with that of wheat; the top price of Town-made was reduced on the 5th Monday to 40s.; Norfolks were unchanged till the fourth Monday, when they were reduced from the nominal rate, 32s. to 30s. per sack, with a very limited sale at the quotations. French and American also on this day receded fully 1s. per sack and brl.; the arrivals of the latter being larger than during any week since the 15th of December, 1857. The closing price of Norfolk was 29s. The supplies from the country have been constantly large, and have greatly interfered with the wheat trade, London millers being thus undersold.

During the five weeks, the receipts have been 93,921 sacks of country made; 8,311 sacks French, &c., and 26,704 brls. American; giving a weekly average of 20,440 sacks and 5,340 brls.

In barley throughout the month there has been scarcely any alteration, London having been very moderately supplied with really fine malting quality, and the seed demand running through the month has taken off all choice lots at full rates. From abroad also less has come to hand, the heavy supplies of low Mediterranean sorts having ceased, and those that were previously stored having been partly worked off in mixture with oats, as cheaper food. Our own stocks of this grain getting reduced, there seems every prospect that whatever foreign arrivals appear they will find a sale, or not remain long in store.

The arrivals during the five weeks have been, in English 17,087 qrs., in foreign 29,075 qrs., making an average of 9,231 qrs. per week, against 13,726 qrs. weekly in February.

The malt trade has been little altered, fair supplies being kept up, and about the same prices realized from the beginning of the month to its close for fine qualities.

The oat trade has been remarkably steady, on short arrivals scarcely any quotable change occurring, and the cause of this grain's not advancing can only be found in the quantity of Russian landed during former gluts, which have served to feed the market in the absence of ship samples. Had it not been, however, for increased supplies from Ireland, it would have been impossible to keep prices down, and even with their help cargoes of sweet Riga and Petersburg qualities have been held at rather more money. From Scotland as well as from foreign ports the supplies have been reduced. On the fifth Monday prices improved 6d. per qr.

The receipts during five weeks have been 5,317 qrs. English, 6,503 qrs. Scotch, 21,880 qrs. Irish, and 27,366 qrs. foreign, giving a total weekly average of only 12,213 qrs., which is 4,991 qrs. weekly below February arrivals.

Beans and peas, in the comparative absence of foreign supplies, till the last week have rather improved in value, especially the former, to the extent of 1s. to 2s. per qr. Boiling peas, which slowly found favour in the cold weather, have again upon its ceasing diminished in consumption: maples and duns remaining scarce have commanded good prices from retail buyers, who prefer them to cheaper substitutes. Of English beans the quantity received has been 4,785 qrs., of foreign 4,593 qrs. Of foreign peas there were only 105 qrs., and 1,663 qrs. English.

In linseed there has been little change: the first Monday of the month noted a rise of 1s., and at this improvement the market has remained with a quiet trade; but cakes all through have been much in request, and notwithstanding some large supplies recently received from the United States, they have commanded about former prices.

The cloverseed trade, checked at first by the frost, on the return of fine weather did not meet the expectation of holders; the season getting late, those who have stocks of foreign have been uneasy at the slackness of the demand, especially as it appears that the first reports of the English crop were below the reality. A good deal of red seed it now appears was produced, but part of it being badly harvested, the extent of the injury was exaggerated, the bulk being fit for sowing, though discoloured; and as the farmers have not received high prices for their wheat, they have been less disposed to buy too dearly. A fair trade came at the month's close, however, at lower rates; and great prices are not now to be looked for, either in red or white seed, or trefoil. Canaryseed had a start during the intense frost, but with mild weather it seems likely again to recede, as the Dutch ports must have some to spare at present prices; and Hambro', now free, is likely to send some spring tares, which have been scarce and dear. Rapeseed has been a better sale, the plants being reported abroad as partly injured. Mustard, hempseed, carraway, coriander, &c., have very little varied during the month's course.

HAMBURG	11 0	11 10	BELGIUM	10 10	11 0

HAY MARKETS.

Saturday, March 27.—SMITHFIELD.—A fair average supply, and a moderate demand.

CUMBERLAND.—Supply tolerably good, and trade rather dull.

WHITECHAPEL.—Both hay and straw moved off slowly, at our quotations.

	At per Load of 36 Trusses.					
	Smithfield.		Cumberland.		Whitechapel	
MEADOW HAY	50s. to	85s.	50s. to	84s.	50s. to	84s.
CLOVER DITTO	70s.	100s.	70s.	100s.	70s.	100s.
STRAW	24s.	30s.	25s.	30s.	26s.	30s.

POTATO MARKETS.

SOUTHWARK WATERSIDE, Monday, March 29.—Since our last export supplies have been light coastwise, but heavy from foreign ports. Our markets having been previously pretty clear, there was a ready demand all last week at much the same prices as quoted on Monday the 22nd inst. The following are this day's quotations:—

Yorkshire Regents	140s. to 190s.	per ton.
Lincolnshire do.	140s. to 160s.	,,
Dunbar do.	140s. to 180s.	,,
Do. reds	90s. to 100s.	,,
Perth, Fife, and Forfar Regents	100s. to 145s.	,,
Ditto ditto reds	90s. to 100s.	,,
French whites	80s. to 95s.	,,
Belgian do.	80s. to 90s.	,,
Ditto reds	100s. to 105s	,,

BOROUGH AND SPITALFIELDS.

LONDON, Monday, March 29.—The arrivals of potatoes, coastwise and by railway, last week, were moderate. The imports were 1,005 tons from Antwerp, 826 tons from Rouen, 837 tons from Dunkirk, 47 tons from Ostend, 80 tons from Tornenzen, 265 tons from Ghent, 270 tons from Calais, and 110 tons from Louvsine. Selected samples are firm and rather dearer, and the value of other kinds is fairly supported.

York Regents	140s. to 200s.	per ton.
Kent and Essex do.	100s. to 160s.	,,
Scotch	120s. to 170s.	,,
Do. Cups	100s. to 110s.	,,
Middlings	60s. to 120s,	,,
Foreign	80s. to 100s.	,,

COUNTRY POTATO MARKETS.—York, March 20: Potatoes sell at 13d. to 14d. per peck, and 4s. to 4s. 3d. per bushel. Leeds, March 23: We had a middling show of potatoes, which sold at 16d. to 16½d. per 21lbs. wholesale, and 17d. to 18d. retail. Richmond, March 20: Potatoes, 4s. 8d. per bushel. IMPORTANT TO FLOCKMASTERS.

THOMAS BIGG,

AGRICULTURAL AND VETERINARY CHEMIST,

BY APPOINTMENT, TO H.R.H. THE PRINCE CONSORT, K.G., &c.

LEICESTER HOUSE, GREAT DOVER-STREET, BOROUGH, LONDON,

Begs to call the attention of Farmers and Graziers to his valuable SHEEP-and LAMB DIPPING COMPOSITION, which requires no Boiling, and may be used with Warm or Cold Water, for effectually destroying the Tick Lice, and all other insects injurious to the Flock, preventing the alarming attacks of Fly and Shab, and cleansing and purifying the Skin, thereby greatly improving the Wool, both in quantity and quality, and highly contributing to the general health of the animal.

Prepared only by Thomas Bigg, Chemist, &c., at his Manufactory as above, and sold as follows, although any other quantity may be had, if required:—

4 lb. for	20 sheep,	price,	jar included	£0	2 0
6 lb.	30	,,	,, ,,	0	3 0
8 lb.	40	,,	,, ,,	0	4 0
10 lb.	50	,,	,, ,,	0	5 0
20 lb.	100	,,	,, (cask and measure	0	10 0
30 lb.	150	,,	,, included)	0	15 0
40 lb.	200	,,	,, ,,	1	0 0
50 lb.	250	,,	,, ,,	1	3 6
60 lb.	300	,,	,, ,,	1	7 6
80 lb.	400	,,	,, ,,	1	17 6
100 lb.	500	,,	,, ,,	2	5 0

Should any Flockmaster prefer boiling the Composition, it will be equally effective.

He would also especially call attention to his SPECIFIC, or LOTION, for the SCAB, or SHAB, which will be found a certain remedy for eradicating that loathsome and ruinous disorder in Sheep, and which may be safely used in all climates, and at all seasons of the year, and to all descriptions of sheep, even ewes in lamb. Price **5s.** per gallon—sufficient on an average for thirty Sheep (according to the virulence of the disease); also in wine quart bottles, 1s. 3d. each.

IMPORTANT TESTIMONIAL.

"Scoulton, near Hingham, Norfolk, April 16th, 1855.

'Dear Sir,—In answer to yours of the 4th inst. which would have been replied to before this had I been at home, I have much pleasure in bearing testimony to the efficacy of your invaluable 'Specific for the cure of Scab in Sheep.' The 600 Sheep were all dressed in August last with 84 gallons of the '*Non-Poisonous* Specific,' that was so highly recommended at the Lincoln Show, and by their own dresser, the best attention being paid to the flock by my shepherd after dressing according to instructions left; but notwithstanding the Scab continued getting worse. In December I informed the 'Agent for the above Specific,' that the flock was not cured, and that it required their immediate attention. The Agent informed me theys hould be at once seen to, but did not do so until *five* weeks afterwards, and in the mean time the Scab spread over the whole flock, that I never saw such a disgraceful sight in my life; and when the Dresser was sent over to inspect the Flock, he decided on not dressing them again, as one-third of the Sheep had lost half their wool. I then agreed with an experienced dresser in Norfolk to dress the flock, and when he saw the sheep he declined doing them, as they were so very bad, and the time of lambing so near. Being determined to have the Scab cured if possible, I wrote to you for a supply of your Specific, which I received the following day; and although the weather was most severe in February during the dressing, your *Specific* proved itself an invaluable remedy, for in three weeks the Sheep were quite cured; and I am happy to say the young lambs are doing remarkably well at present. In conclusion, I believe it to be the safest and best remedy now in use.

"I remain, dear Sir, your obedient servant,

"For JOHN TINGEY, Esq.,

"To Mr. Thomas Bigg." "R. RENNY.

In addition to the foregoing, he has very materially improved, as well as considerably reduced the price of his Dipping Apparatus; and he would venture to suggest that no Flockmasters ought now to be without one. Price in London.

Apply (in the first instance) to Beta, care of T. W. Clough, Esq., Solicitor, Huddersfield.

FRAMPTON'S PILL OF HEALTH. Price 1s. 1½d. and 2s. 9d. per box.—This excellent Family Pill is a medicine of long tried efficacy for purifying the blood, so very essential for the foundation of good health, and correcting all Disorders of the Stomach and Bowels. Two or three doses will convince the afflicted of its salutary effects. The stomach will speedily regain its strength; a healthy action of the liver, bowels, and kidneys will rapidly take place, and renewed health will be the quick result of taking this medicine, according to the directions accompanying each box. PERSONS of a FULL HABIT, who are subject to headache, giddiness, drowsiness, and singing in the ears, arising from too great a flow of blood to the head, should never be without them, as many dangerous symptoms will be entirely carried off by their timely use. The following extract of a letter from Mr. Thomas Province, of Winchmore Hill, Middlesex, is another proof of the Invaluable Medicinal Properties of FRAMPTON'S PILL OF HEALTH:—"For upwards of nine years I have experienced the efficacy of this excellent medicine. I had long previously been afflicted with headache and indigestion, but a friend having induced me to make a trial of Frampton's Pills, I now inform you that a few doses gave me great relief; and during this long period of time I have taken them in preference to any other medicine; and I have the happiness of saying that I never had a better state of health, which I attribute to Frampton's Pills. I beg further to add, that this medicine is in general use by my family, and we know of nothing to equal it." FOR FEMALES these pills are truly excellent, removing all obstructions, the distressing headache so very prevalent with the sex, depression of spirits, dulness of sight, nervous affections, blotches, pimples, and sallowness of the skin, and give a healthy, juvenile bloom to the complexion. To MOTHERS they are confidently recommended as the best medicine that can be taken; and for children of all ages they are unequalled. These Pills unite the recommendation of a mild operation with the most successful effect, and for elderly people, or where an occasional aperient is required, nothing can be better adapted. In consequence of the great and increasing demand, the Proprietor has obtained permission from her Majesty's Commissioners to have the name and address of "Thomas Prout, 229, Strand, London," impressed upon the Government stamp affixed to each box. Sold by all Vendors of Medicine.

Patronized by the Principal Farmers and Graziers in the Kingdom.

CUFF'S FARMER'S FRIEND.

One dose of this invaluable medicine will cure the SCOUR or LOOSENESS in Lambs, Calves, Sheep, Colts, Heifers, Steers, and all Cattle, without leaving costiveness; and given occasionally to Beasts whilst fattening will promote a healthy and thriving condition. It will also perfectly cure the FRET, COLIC or GRIPES in Horses. Price 1s. 8d. or 3s. per Bottle.

CUFF'S FOOT-ROT POWDER

Is a cheap and effectual remedy for the FOOT-ROT or HALT, a single Packet of which will cure One Hundred Sheep, and large Flocks may be soon freed from the Disease by its use. It has been extensively used and highly approved of for nearly thirty years by large Sheep Breeders throughout the Kingdom. Price 1s. per Packet.

CUFF'S FLY, SCAB & MANGE OIL

Will very quickly destroy MAGGOTS in Sheep, and LICE or VERMIN in all animals. It will also cure the MANGE, and SKIN DISEASES in Horses or Cattle, and effectually cleanse a Flock of Sheep from the SCAB or SHAB. Price 1s. 8d. and 3s. per Bottle.

THE BRITISH SHEEP WASH

Is used for Dipping or Dressing Sheep and Lambs, without boiling, to prevent the Fly striking, and the Scab or Shab from spreading, and effectually to destroy TICKS, LICE, and VERMIN in Sheep. Price 2s. 9d., 5s., and 10s. per Jar; or 2s. 6d. per packet.

SHERWOOD'S ORIGINAL DRIFFIELD OILS

Are strongly and confidently recommended for preventing GANGRENE or MORTIFICATION after Lambing or Calving, and for Healing CUTS, STABS, WOUNDS, BRUISES, STRAINS, SWELLINGS, &c., &c.. As these Oils are in constant use by some of the most celebrated Breeders in the world, and have maintained a reputation about fifty years, it would be superfluous to enlarge upon their value and importance. Pints, 2s. 6d., Quarts, 5s.

Prepared by J. H. CUFF, No. 10, Smithfield Market, London, and sold by Druggists and Medicine Vendors

None is Genuine unless signed by J. H. CUFF in writing.

KEATING'S COUGH LOZENGES.

"A SLIGHT COLD,"—if its first symptoms are not arrested, too often lays the foundation of a variety of *Pulmonary Complaints*, including *Winter Cough*, *Asthma*, and other constitutional derangements. The evil consequences of these disorders may be easily averted or subdued by keeping at hand a supply of the above celebrated LOZENGES, which have now stood the test of public experience for upwards of half a century. The Testimonials to their efficacy have been voluntarily given by the most eminent of the Faculty, as well as by all classes of private individuals. Containing neither opiates nor any injurious anodyne, they may be safely taken by the youngest child or the most delicate female.

VALUABLE TESTIMONIAL.

CURE OF ASTHMA OF SEVERAL YEARS' STANDING.

Cainscross, near Stroud, Gloucestershire.

SIR,—Having been troubled with Asthma for several years, I could find no relief from any medicine whatever, until I was induced about two years ago to try a box of your valuable Lozenges, and found such relief from them that I am determined for the future never to be without a box of them in the house, and will do all in my power to recommend them to my friends.

If you consider the above testimonial of any advantage, you are quite at liberty to make what use of it you please.

I am, Sir, your most obliged servant,
W. J. TRIGG.

Thomas Keating, Esq.

Prepared and sold in Boxes, 1s. 1½d., and Tins, 2s. 9d., 4s. 6d., and 10s. 6d. each, by THOMAS KEATING, Chemist, &c., 79, St. Paul's Churchyard, London. Retail by all Druggists and Patent Medicine Vendors in the world.

N.B.—To prevent spurious imitations, please to observe that the words "KEATING'S COUGH LOZENGES" are engraven on the Government Stamp of each Box, without which none are genuine.

KEATING'S PALE NEWFOUNDLAND COD LIVER OIL, perfectly pure, nearly tasteless, and free from adulteration of any kind, having been analyzed, reported on, and recommended by Professors TAYLOR and THOMSON, of Guy's and St. Thomas's Hospitals, who, in the words of the late Dr. PEREIRA, say that "The finest oil is that most devoid of *colour*, *odour*, and *flavour*," characters this will be found to possess in a high degree. Half-pints, 1s. 6d.; Pints, 2s. 6d.; Quarts, 4s. 6d.; and Five-pint Bottles, 10s. 6d., Imperial Measure.

79, ST. PAUL'S CHURCHYARD, LONDON.

ELEGANT PERSONAL REQUISITES.

Under the Patronage of and Royal Family the several Sovereigns

Her Majesty "The Queen," of Great Britain, and Courts of Europe,

AND UNIVERSALLY PREFERRED.

ROWLANDS' MACASSAR OIL

Is universally in high repute for its successful results during the last half century in the GROWTH, RESTORATION, and IMPROVEMENT of

THE HUMAN HAIR.

It prevents Hair from falling off or turning grey, strengthens weak HAIR, cleanses it from Scurf and Dandriff, and makes it BEAUTIFULLY SOFT, CURLY, and GLOSSY.

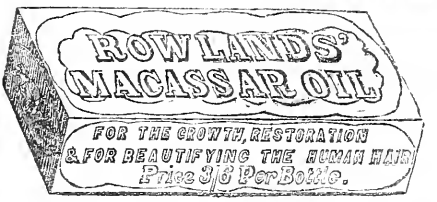
In the growth of

THE BEARD, WHISKERS, AND MUSTACHIOS

it is unfailing in its stimulative operation. For CHILDREN it is especially recommended as forming the basis of A BEAUTIFUL HEAD OF HAIR.

Price 3s. 6d.; 7s.: Family Bottles, equal to four small, 10s. 6d.; and double that size, 21s.

IMPORTANT CAUTION.



To prevent the substitution of *Spurious Imitations* for the genuine article by unprincipled shopkeepers, A. R. & Sons here add a small copy in *outline* of their Label (as it appears round the bottle) from the burin of Messrs. Perkins, Bacon & Petch, the eminent engravers, of London.

Another portion bears the Signature of the Proprietors, in Red Ink—

"A. ROWLAND AND SONS."

ROWLANDS' KALYDOR,

AN ORIENTAL BOTANICAL PREPARATION

FOR IMPROVING AND BEAUTIFYING THE COMPLEXION AND SKIN.

It eradicates all REDNESS, TAN, PIMPLES, SPOTS, FRECKLES, and DISCOLORATIONS, and renders

THE SKIN SOFT, FAIR, and BLOOMING.

It obviates all the effects of Climate on the Skin, whether with reference to cold and inclemency, or intense solar heat, and affords immediate relief in cases of sunburn, stings of insects, or incidental inflammation. Gentlemen after shaving will appreciate its softening and ameliorating properties.—Price 4s. 6d. and 8s. 6d. per bottle.

CAUTION.—The words Rowlands' Kalydor are on the Wrapper, and their signature, "A. Rowland & Sons," in red ink, at foot.

A GOOD SET OF TEETH

Ever insures favourable impressions, while their preservation is of the utmost importance to every individual, both as regards the general health by the proper mastication of food, and the consequent possession of pure and sweet breath.

ROWLANDS' ODONTO,

OR, PEARL DENTIFRICE,

Compounded of the choicest and most recherché ingredients of the ORIENTAL HERBAL, and of inestimable value in

PRESERVING AND BEAUTIFYING THE TEETH,

IMPARTING A PEARL-LIKE WHITENESS,

STRENGTHENING THE GUMS,

And in rendering

THE BREATH SWEET AND PURE.

CAUTION.—The words Rowlands' Odonto are on the Label, and A. Rowland & Sons, 20, Hatton Garden, on the Government Stamp affixed on each box.—Price 2s. 9d. per box.

Sold by A. ROWLAND & SON, 20, Hatton Garden, London, and by Chemists and Perfumers.

BLAIR'S GOUT AND RHEUMATIC PILLS.

Price 1s. 1½d. and 2s. 9d. per box.

THIS preparation is one of the benefits which the science of modern chemistry has conferred upon mankind; for during the first twenty years of the present century to speak of a cure for the Gout was considered a romance; but now, the efficacy and safety of this medicine are so fully demonstrated by unsolicited testimonials from persons in every rank of life, that public opinion proclaims this as one of the most important discoveries of the present age; and, in testimony of its efficacy, Mr. W. Burch, Chemist, West Bromwich, writes—"Nov. 8th, 1856. Gentlemen, The enclosed Testimonial was received by me from a customer residing in this town. Yours respectfully, W. BURCH. To Messrs. Prout & Co." Mr. ARKINSTALL, of the Lyng, West Bromwich, says :—"I have much pleasure in bearing my testimony to the wonderful efficacy of Blair's Gout and Rheumatic Pills. Having been a great sufferer from rheumatic gout, I have upon various occasions had recourse to them, and am happy to say that however acute and distressing the pain may be, I always receive relief in an almost incredibly short time, even after taking only one dose. If taken in the early stage of the disease they dissipate it; if later they ease the pain and cure much sooner than any other medicine I ever made use of. I would not be without them on any account."

FURTHER PROOF OF THE GREAT EFFICACY OF BLAIR'S GOUT AND RHEUMATIC PILLS.—Forwarded by Mr. Reinhardt, Chemist, Hull. Sir,—Enclosed is a testimonial from a customer of mine, who is well known about here: he speaks in the highest terms of Blair's Gout and Rheumatic Pills, and would be glad to give information to anybody. "To Mr. Reinhardt, 22, Market-place, Hull. December 4th, 1855. Dear Sir,—I have been afflicted with rheumatism for 12 years, during which time I have tried almost everything, both internally and externally, but could not obtain any permanent relief. A short time ago I purchased a 2s. 9d. box of Blair's Pills of you, and before I had taken the whole of them I was more free from pain than I had been for the last dozen years. You will please let me have another box, as I mean to keep them by me in case I should again require them, and oblige, dear Sir, yours obediently, JEREMIAH GAMESS."

These Pills require neither attention nor confinement, and are certain to prevent the disease attacking any vital part. Sold by all medicine vendors. See the name of "Thomas Prout, 229, Strand, London," on the government stamp.

THE ROYAL FARMERS'
AGRICULTURAL AND COMMERCIAL
INSURANCE COMPANY.

3, NORFOLK STREET, STRAND, LONDON, W.C.

RATES.

HAIL.—Wheat, Barley, Oats, and other ordinary Crops, without limitation, as to quantity grown. } 6d. per Acre.

The last Bonus (1856) was upwards of 66 per Cent. to Insurers of the four previous years, and in proportion to Insurers for a less period.

The Royal Farmers' is the first Office which introduced this additional means of protecting the interest of the Farmers.

It should be borne in mind that no care whatever can prevent damage by Hail, and that there is no means of protection other than that now offered.

The losses by Hail Storms within the last few years in districts where parties neglected to insure, have been very severe; and many persons were reduced from prosperous circumstances to the painful necessity of availing themselves of a public subscription—a necessity they might have avoided by the trifling payment of Sixpence per Acre.

FIRE.—Fire Insurances of every description at moderate rates. Farming Stock without average, 4s. per cent.

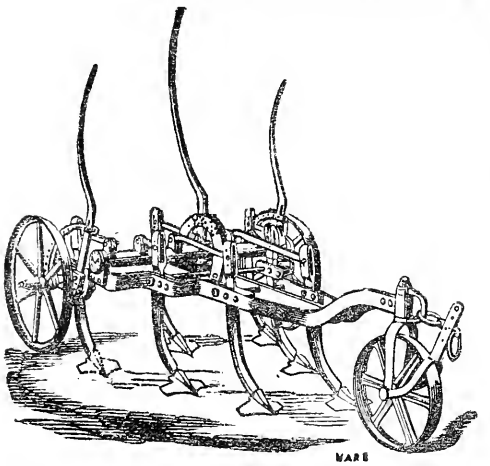
LOSSES paid immediately after the amounts have been ascertained.

LIFE.—Life Insurances on moderate terms by Policies payable to the Registered Holders.

Further particulars may be had at the Chief Office, or of the Agents.

ADDITIONAL AGENTS WANTED. Application to JOHN REDDISH, Secretary and Actuary.

COLEMAN'S PATENT PRIZE CULTIVATOR.



FOR Spring work this Implement is most effectual and economical, thoroughly breaking up and pulverizing the surface without turning it over, and at one-third the cost of ploughing.

Its strength, convenience of management, and ease of draught are unrivalled.

The Public are respectfully reminded that besides a large number of FIRST PRIZES given by the Royal and other principal Societies in the Kingdom, the Royal Agricultural Society of England, at their Triennial Competition, at Chelmsford, awarded Coleman's Cultivator TWO FIRST PRIZES, as the best Cultivator, and the ONLY FIRST PRIZE FOR PARING.

MANUFACTURED BY

COLEMAN & SONS, CHELMSFORD,

Of whom Prices and Testimonials may be obtained post free.

ALSO,

COLEMAN'S PATENT PRIZE EXPANDING HARROWS,

AND

COLEMAN'S IMPROVED HANSON'S PATENT PRIZE POTATO DIGGER,

Of which Implement COLEMAN & SONS are Sole Manufacturing Agents for England and Wales.

CARSON'S
ORIGINAL ANTI-CORROSION PAINT,

Specially patronized by the British and other Governments, the Hon. East India Company, the principal Dock Companies, and other public bodies, &c., is particularly recommended to the Nobility, Gentry, Agriculturists, Manufacturers, West India Proprietors, and others, it having been proved by the practical test of more than seventy years to surpass all other paints as an out-door preservative. It is extensively used for the protection of wooden houses, farm, and other out-buildings, farming implements, conservatories, park paling, gates, iron railings, iron hurdles, copper, lead, brick, stone, old compo, and stucco fronts, and tiles to represent slating. The superiority of the Anti-Corrosion to every other paint for out-door purposes may be easily inferred from the simple fact, that its use has been always most strenuously opposed by Colour Manufacturers, Painters, Oil and Colourmen, and others interested in the sale of common paints. It is also very economical, any labourer being able to lay it on.

COLORS:

WHITE STONE	34s. per cwt.	DARK CHOCOLATE	30s. per cwt.
LIGHT Do.		BRIGHT and DARK RED	
DRAB or PORTLAND Do.		COPPER	
BATH Do.		BLACK	
LIGHT YELLOW Do.		INVISIBLE GREEN	46s. per cwt.
DARK YELLOW Do.		DEEP GREEN	56s. „
LIGHT and DARK OAK		BRIGHT GREEN	56s. „
BROWN	30s. per cwt.	BLUE (for Carts and Wagons)	56s. „
LIGHT and DARK LEAD			
LIGHT CHOCOLATE			

In casks of 28, 56, and 112 lbs. each, and upwards.—OIL & BRUSHES.—The Original Anti-Corrosion Paint is only to be obtained of

WALTER CARSON & SON,

(Successors to the Inventors)

9, GREAT WINCHESTER STREET, OLD BROAD ST. (NEAR THE ROYAL EXCHANGE) LONDON, EC.

who will show 700 most flattering Testimonials received from the Nobility, Gentry, and Clergy, who have used the Anti-Corrosion for many years at their country seats.

A Copy of the Testimonials will be sent on application,

No Agents.—All Orders are particularly requested to be sent direct.

ROBERT AND JOHN REEVES,
BRATTON, WESTBURY, WILTS,

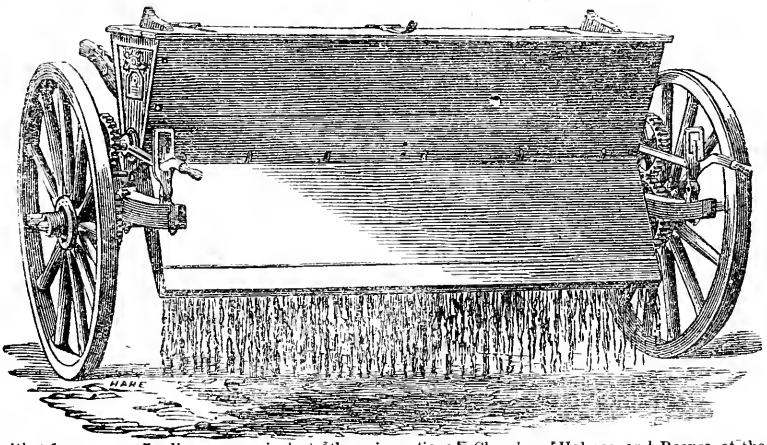
BEG to call attention to their useful Implement,

REEVES'S DRY MANURE DISTRIBUTOR,

which is equal to any for top drilling with all kinds of manure, and is superior to all others for putting in Soot.

PRICE.....£10.

THREE PRIZES were awarded to it last year—at the Bath and West of England Society, Newton; at the Royal Agricultural Society of England, Salisbury; at the Yorkshire Society, at York.



"The Dry Manure Distributors furnished one of the most interesting trials of the whole meeting. Who ever has witnessed the effect of hand-sowing guano on a dry windy March day will not refuse the epithet *humane*, as well as economical, to these inventions. Chambers, Holmes, and Reeves, at the descending scale of 20 gs., £14, and £10, are the names and the corresponding prices that offer themselves; that of Mr. Reeves, at the lowest sum, being introduced first to the Society at this meeting. The machinery of the two dearer ones is most ingenious, and almost inevitably exact in their steady delivery of the manure, whether damp or powdery. But Mr. Reeves' lower-priced implement is a positive boon to the *labourer* as well as the farmer."—*Report on Trial of Implements at Salisbury Meeting, by C. W. Hoskyns.*

CHANDLER'S PATENT LIQUID MANURE DRILL,

After the test of Ten years, is still acknowledged to be the most simple and efficient.

R. & J. REEVES have made arrangements with Mr. CHAMBERS to Manufacture his PATENT LIQUID DROP COULTER, so that those who prefer the bunching system can now have the most complete Drill that has been yet offered to the public.

REEVES' PATENT ECONOMICAL DRILLS,

For Drilling all kinds of Artificial Manure with Roots or Grain, in their pure state, without the expensive system of mixing them with a large quantity of ashes. They will Drill from 2 to 20 Bushels per Acre, and will be found very useful when water is too scarce to use the Liquid Drill, and also on light down land. Prices from £8 to £14. They gained Two Prizes and a Silver Medal last year (being their first year).

REEVES' PATENT HAND DRILL,

For Gardeners, Market Gardeners, and small Occupiers, will Drill or Bunch Onions, Parsnips, Carrots, Peas, Beans, Wheat, or any other Grain; will drop Mangel Seed in Bunches at different distances, and will be found very useful for persons accustomed to thin seeding, as they will drop 2 or 3 corns (only) in Bunches at 6 inches apart.

Price List and particulars sent post free on application.

BRATTON IRON WORKS, March 27, 1858.

RANKIN'S
NEW PATENT CORN SCREEN AND SMUT MACHINE
MANUFACTURED SOLELY BY
R. & J. RANKIN, UNION FOUNDRY, LIVERPOOL.

THE very great improvements made in this new PATENT SMUT MACHINE comprise an arrangement by which (in addition to freeing and purifying the Wheat from *all Smut, however badly it may be affected*) all Sand, Seeds, and heavy matter are extracted in one operation. The Machine has a Double Action upon the Wheat, and combines all the important advantages of the original (Grimes') Machine, with the addition of those of a *Wire Screen*. The following Testimonials prove that the Machine is found to be the best of the kind in use:—

Messrs. R. & J. Rankin, Liverpool. [COPY.] Slane Mills, 14th August, 1856.

DEAR SIRS,—We have much pleasure in saying that the Patent Smut Machine has given us every satisfaction, and for so far has not cost us one penny. The working parts—that is, bearings, &c., are just as good as the first day we put it to work, now twelve months ago, and it has run nearly every working-day since.

Yours, truly,
(Signed) WETHERILL, POWELL, & Co.
Boston, 25th July, 1857.

GENTLEMEN,—Your Smut Machine I consider to be the best invented, and after working it seven years I find it to be as effective in its operations as it was the first week it was erected.

I shall be happy at any time to render an account of it and its good qualities when called upon; and I am, Gentlemen, your obedient servant,
(Signed) A. REYNOLDS (late Reynolds & Son).

RANKIN'S NEW PATENT BONE MILLS.

These MILLS are adapted for the use of Farmers and Manufacturers, and are made in all sizes. They are a most decided improvement upon those in ordinary use, taking much less power to drive them, whilst they work far more efficiently. The Mills will Grind the largest and hardest Bones with ease to any degree of fineness that may be wished, there being provision made to regulate their working as may be required.

Manufacturers will find this Mill to be much more durable, to Grind quicker, and to a greater degree of fineness than any other.

TESTIMONIAL. *Amersham, Bucks, November* 8, 1855.

This is to certify that Messrs. Rankin, of Liverpool, have fixed one of their Four-horse Bone Mills for me, with which I am perfectly satisfied, not only as it regards the power taken to drive it, but also the fineness of the Bones when ground. The principle I consider superior in every respect to the old ones. The work is exceedingly well done, not only as it regards the Mill itself, but the Horse Gear is of a very superior character. I shall be happy to show the Mill when working, or answer any enquiries.

(Signed) THOMAS H. MORTEN.

Messrs. R. & J. Rankin, Liverpool.

Samuel Jonas

THE FARMER'S MAGAZINE.

MAY, 1858.

PLATE I.

PORTRAIT OF MR. SAMUEL JONAS.

PLATE II.

VICTORIA; A SHORT-HORN COW.

MR. SAMUEL JONAS.

There are few better representatives of his order than Mr. Sam. Jonas, of Ickleton. A shrewd judge and a spirited man of business, with every ability to carry out his intentions, he brings the character of the British farmer quite up to the standard of our own times. With something of the old school in his bearing and appearance, there is no one more alive to the advancement and improvement the art of agriculture must achieve. It is, indeed, from the experience of such men that we gather the only reliable test of the progress we are making. Theorists may write, and amateurs may talk, but it is the practical man who works. He flourishes or falls with the pursuit; and makes it his first duty to see what he can adopt and what he shall avoid. The farmer shuts himself up no longer in his own home and to his own prejudices. On the contrary, you find him all the world over; a farmer still, learning and sifting out all he can for the advantage of his profession.

"Sam Jones," as he is familiarly termed, is one of these—known all the world over. You see him at all our great meetings, bustling about either as one in authority, or in some other way quite as much interested in what is going on. It is not for himself alone either that he is speaking or working. On many an occasion ere this he has been one of the best champions of his class. There is moreover an independence of action and earnestness of purpose in what he does that is always sure to tell. Whether it be at a local meeting in his own county, or on a grand field-day in Hanover-square, there is no farmer speaks up for his fellows with more effect than Mr. Jonas. He occupies no ambiguous position, but is thoroughly identified with those he professes to feel for. And so when he says, the farmers "must have this," or "they wont have that," the Council know it is no idle boast or vain prayer they are now hearing of.

Mr. Jonas—like his relative Mr. Jonas Webb—is a native of Suffolk. He was born at Great Thurlow, in that county, on the 27th of September, 1802, so that he is now in the fifty-sixth year of his age. It is, however, with the county of Cambridge that, until very recently, he has been more identified, having farmed for a number of years at Ickleton. His doings even as a public man are all more or less associated with this district. He wrote, for instance, the Prize Essay on the farming of Cambridgeshire, for the "Journal of the Royal Agricultural Society"—the farming of his own county, as it was then called. This paper was an especial favourite with the late Mr. Pusey, the then Editor of the Journal, and often cited by him as an example of what such an essay should be.

More in connection—at least by its boundaries—with his present residence, Mr. Jonas was instrumental in forming the Saffron Walden Agricultural Society, of which it is almost needless to add he is a zealous supporter. His sideboard gives evidence with what success as an exhibitor.

Of the great national Society of the kingdom he

has been almost from the first a prominent member. His name has been on the Council for no less than eighteen years, while he has been actively employed as a member of the sub, or really working committees. His services have not even ended here, as he has officiated as steward of the cattle-yard at five of the great annual meetings. His knowledge of his subject, unwearied activity, and business-like tact have more than usually well qualified him for such an appointment.

Some years since he was equally distinguished as a leading man at the meetings of the Protection Society—a cause of which he was a most energetic and determined supporter. He wrote a good deal at the time, in maintenance of the principles he so warmly advocated and so conscientiously believed in. Although he fought a losing battle, he retains the friendship of many good men he here first became acquainted with. They saw and appreciated how thoroughly he was in earnest.

Mr. Jonas has been for some years a Director of the Royal Farmers' Insurance Institution; and is, in fact, ever ready to take his part in promoting the interests and watching over the welfare of his brother farmers.

Mr. Jonas has left Ickleton, and is now occupying about three thousand acres of land at Chrishall Grange, near Saffron Walden, in Essex. The largest portion of this extensive holding, when first engaged on by him, was in as exhausted and as foul a state as it was possible to imagine. It was truly uphill work. His proverbial energy and determination have, however, brought it round; and we believe we are justified in saying that, for the spirited manner in which he cultivates his land, and the large sums he expends in food for stock and artificial manures, Mr. Jonas ranks worthily with Mr. Hudson of Castle Acre, and other such eminent English farmers.

We usher him accordingly into their company; where his friend Mr. Webb first "sat" at our request, now some years since.

PLATE II.

VICTORIA, A SHORT-HORN COW;

THE PROPERTY OF LIEUT.-COLONEL TOWNELEY, OF TOWNELEY PARK, BURNLEY.

VICTORIA, a red roan cow, bred by Colonel Towneley, calved October 30, 1853; got by Valiant (10989), dam (Jenny Lind) by Bem (8881), g. d. (Ruby) by Selim (8545), gr. g. d. (Lady) by the Earl of Aylsford (6155), gr. gr. g. d. (Lily) by Sir Robert (5178), gr. gr. gr. g. d. bought at the Earl of Aylsford's sale.

Victoria ranks amongst the most famous of prize animals. She has already taken no less than fifteen first prizes, at meetings of the Royal Agricultural Society of England, of the Yorkshire Society, the Midland Counties Society, the Smithfield Club, and others of more local repute. At the Chelmsford meeting of the Royal Society, in 1856, she was awarded the first prize as the best heifer in-calf, which she produced in the September following. At the Salisbury show, in 1857, she was awarded the first prize as the best cow. In the December of the same year she took the first prize as the best of her breed, and the GOLD MEDAL as the best of all the cows at the Birmingham Fat Cattle Exhibition. The next week she was again declared the first prize and GOLD MEDAL cow at the Smithfield Club. Never before this has any one animal been so highly honoured.

Victoria is really a splendid cow—of most magnificent proportions, perfect symmetry, and admirable quality. Her head is neat, breadth great, and her chine, chest, and fore-quarter wonderful—as, indeed, is she good all through. She had fed, moreover, most evenly, and was an extraordinary specimen of what a fat beast should be. Victoria, however, was not destined for the butcher, but returned after her last triumph at the Smithfield Club to Towneley Park. She was even said to be in calf when exhibited—a declaration that, it will be remembered, caused some talk at the time. Victoria's praises should be sung over the "Herd Book," and not in Mr. Jeffries' window.

THE WANDLE VALLEY.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

The farming of the valley of the Wandle river partakes rather too much of the character of the other suburban districts. The high prices paid in the metropolis for certain roots and household vegetables, and the ready access to almost inexhaustible supplies of organic manure, enable most of the holders of the land near London to cultivate their ground in defiance of all rotations, regardless of almost any other object than that of the highest-priced produce. The farming of the Wandle valley is not an exception to this rule. From its commencement at Croydon till it terminates at Wandsworth, the banks of this bright chalk stream are hardly ever more than ten miles from Westminster Bridge; the influence of London upon the lands around it is therefore evident at every footstep we advance along all the rich vale through which it flows towards the Thames.

Still there are some things to be noted even here, worthy of the attention of the farmers of other districts of our island. The very geological situation of the valley is worthy of notice. The Wandle, in fact, traverses pretty closely, for a considerable portion of its course, the line which marks the division of the London and the plastic clays, from the great southern chalk formation. As the traveller descends the valley from Croydon, he will find the clay hills of the London basin sloping down to the northern bank of the river, and the chalk hills bounding his view, and forming the soils of the south side of the stream. From the base of these considerable chalk hills issue forth the copious bright springs which form the Wandle river; and on their northern slopes rest the calcareous loam soils, known in Surrey as "the marme lands"—soils long since correctly described by Stevenson as deep hazel loams resting on the chalk, and varying in depth with the elevation: very deep at the base of the hills, and thinning off to three or four inches in ascending to the Downs. When deep, there is no drawback to their fertility. When shallow, pale, and inclining to clay they are considered to form backward soils in the spring. They are described by Mr. Trimmer as forming a narrow band extending on the north-side of the chalk hills from Croydon to Guildford (*Jour. Roy. Ag. Soc.*, vol. xii., p. 488).

If the farmer, in his way, during the month of May, from London to "The Derby," alights for an hour or two at the Carshalton station, he will find himself on this marme soil. He will first see around him extensive fields of lavender and other scented oil-producing plants; and leaving them, he will enter upon the marme farms, held by considerable and enterprising holders. He will find here the ordinary powerful Kentish turnwrest plough chiefly employed; and if he has not been used to see it in operation, he will hardly fail to note how much better it does its work than its first appearance would lead the stranger to anticipate.

It was on these lands that, in the past month of April, I found the powerful steam-ploughs of Mr. Fowler. They were at work on a sainfoin field of the hazel loam to which I have before alluded. Around these were assembled a group of intelligent farmers, with Garrett of Leiston, and other zealous and scientific implement makers. Here I had the pleasure of again noting the excellent work which these steam-ploughs accomplished, the evenness and depth of the furrows, and the uninterrupted steadiness with which the machinery accomplished its allotted task.

Few spots could have been better chosen for such trials than this field at Woodcote; the soil being of an even texture; the field level and extensive, and not altogether devoid of historical recollections, which might serve to cheer on the skilful modern implement maker in his difficult task; since, only a few fields off, in the same hamlet of Woodcote, is found the site of the old British, and afterwards Roman Noviomagus, where it is pretty certain rude old British, and Roman ploughs once merely roughly-stirred the surface of the ill-cultivated land, and where the ploughman could not venture forth to his miserably-executed task without an armed attendant to protect him and his team from the robber. Strange advances these, from the old wooden plough then employed, made by the ploughman's own hands, and dragged slowly through the soil by half-a-dozen ill-fed horses or oxen, to the ploughs of the turnwrest, and of Ransome, and Howard, and Fowler!

Of the steam plough, I am well-disposed to speak hopefully. Much has already been done with it: practice and experience will in time assuredly do far more to render it practically available; and this remark may apply not only to the plough dragged through the soil by portable engines, but to the too-much-neglected digging machines, which have been hitherto only partially

successful. The existing general feeling of the farmers of Surrey, with regard to the steam plough, is much the same as those which have been pretty well described by Mr. C. W. Hoskyns, in his report upon the implements of the Salisbury Meeting, where he observes (*Jour. Roy. Ag. Soc.*, vol. xviii., p. 424): "It is remarkable, and may be accounted for by those who can best explain the alternations of public feeling and opinion, that at Chelmsford, the year before, the one expression heard on every side was, in various modes of exclamation, to the effect that 'at last the problem of steam-culture was solved!' while at Salisbury, where the preparations for this new class of trials were on a scale far larger, and twice the number of competitors were actually on the field (several more having been entered), the general expression was quite the other way. Not that the interest shown, or the concourse of spectators, was less; but a feeling the opposite of anything like sanguine expectation, or the prospect of realized results, seemed to have gained ground during the lapse of the twelvemonth. Whether it was that there had been time to reflect that, after all, there was nothing really new in ploughing by steam, except perhaps in the subordinate ingenuity of improved details in connecting the implement with the engine, or in turning at the headlands, or whether simply because the novelty of the thing as matter of competitive trial had lost its first freshness, the eager expressions of expectation heard before had subsided into a tone and attitude of mere criticizing interest, somewhat difficult indeed either to accommodate, or, in the language of the police, to 'keep back,' so that the ploughs, and workmen attending the machinery, might have room to act, but far from exhibiting the ready and impulsive conviction of a thing accomplished, that had been noticed the year before.

"Of the actual trials themselves, at Salisbury, to say much is impossible. Such a soil, on such a situation, hardened to such a condition not only by its own flinty nature, but by the long-continued influence of one of the most extraordinary seasons that has ever been known, were enough to render any trial practically abortive. But no one who saw the work performed, even under these adverse circumstances, by Mr. Fowler's plough, could doubt that, in his case at least (not to the least disparagement of the other competitors), steam-*ploughing*, as such, had attained a degree of excellence comparable in point of execution even with the best horse-work. As to the relative economy, there seems little reason to doubt that the calculations arrived at by Mr. Amos and others the year before, at the adjourned trial at Boxted Lodge, were sufficiently near the truth to leave a very inconsiderable difference in favour of horse-work. And if this be true as a comparison, merely taking acre for acre, or hour for hour, every one who knows the supreme value of *time* in the autumn months on clay soils, and the difference, in capacity of *day-work*, between a horse and a steam-engine, must be aware that a new multiplier at least of 2, if not more, may be placed to the credit of the steam-engine, regarded as an available power or auxiliary when work is pressing, and when, according to a well-known poetical authority, the best, or rather only method to lengthen the shortening days, is to 'steal a few hours from night.'"

On the right-hand side of the road leading through Woodcote to Banstead, the traveller will pass "The Oaks," once the beautiful hunting seat of the Derby family, the early and powerful supporters of the races at Epsom, whose former powerful influence there is still known throughout the land in the "Derby" and the "Oaks." About a quarter of a mile beyond this seat commences the yet unenclosed portion of Banstead Downs, which a few generations only since extended from Epsom Downs to Croydon; and to the pedestrian or the equestrian traveller on his road to Epsom, I commend the open down to the right of the road as one of the most picturesque routes he can select. He will see here the farming of the most thin-skinned chalk soils, intermixed here and there with fields of stiffer soil, and of the diluvian alluded to by Mr. H. Evershed in his prize report on the Farming of Surrey (*Jour. Roy. Ag. Soc.*, vol. xiv., p. 395); and, during nearly the whole distance between "The Oaks" and Epsom Downs, the explorer will traverse an elevated ridge commanding the finest views of the valleys of the Wandle and the Thames, backed by the distant hills of Middlesex and Buckinghamshire.

As is remarked by Mr. Evershed, in many instances the natural herbage which clothes the sides of the chalk ridge, producing alike an imposing prospect and very useful sheep pasturage, has been broken up and brought under tillage; but the change has seldom produced satisfactory results, the unlevel position of the ground opposing a natural barrier to its cultivation, while the scantiness of the produce forms a very insufficient return for the necessary outlay. Under these circumstances the Downs of Surrey will probably long remain one of the most prominent features of a very beautiful locality. The size of the farms in this district varies from 200 to 600 acres, the average being about 300—the rental averaging about one pound per acre. The course of cropping as we recede from London is commonly the four or five-shift, viz.: 1. Turnips; 2. Barley; 3. Seeds; 4. Wheat, or 5. Oats. Sainfoin is extensively grown on the

soils having a subsoil of chalk at a moderate distance. The irrigation system is not very extensively practised in the valley of the Wandle, although its waters (which bubble out of the base of the chalk in so many directions) are well adapted for the purpose. It is water containing the same foreign substances as those which irrigate the noble meads of the valleys of the Itchen, the Trent, the Wiltshire Avon, and the Kennett. The water of the Wandle, when examined by Professor Way, was found to contain in an imperial gallon—

Organic matter	1.74
Silica	0.45
Carbonate of lime	16.00
Carbonate of magnesia.....	0 47
Common salt.....	1.38
Sulphate of soda	0.98
Sulphate of potash.....	0.33
Total foreign substances	21.35

In this water, therefore—and the irrigators of other districts will do well to ponder over the fact—is to be found hardly any other substance of a fertilizing nature for the grasses than carbonate of lime. This salt is here held in solution chiefly by the presence in the water of a considerable proportion of carbonic acid gas. This is parted with by the water when heated to boiling, and then nearly 12 grains per gallon out of 16 of its carbonate of lime is deposited. A similar effect is produced by exposing the water in an open vessel to the action of the sun's rays, and it is probable these phenomena may in some degree account for the excellence of the chalk formations' waters for the purposes of grass irrigation.

Many of these things attracted the attention of Arthur Young, who often visited this valley. It was at the farm of Waddon Court, more than half a century since, that he was frequently the guest of the eccentric John Parker, who there farmed more than 2,000 acres. It was here that Young used to meet John Marshall, Grose (the antiquarian), the Boscawens, and a few other enlightened enquirers after truth. The modern agriculturist who treads over the same ground will proceed with far greater advantages than those who, towards the close of the last century, were thus accustomed to assemble together. Such an explorer will have that advanced science to aid him of which poor Arthur Young was wont to so feelingly lament his deficiency. The visitor in our day will moreover, be cheered on by observing, many things accomplished here of which the Surrey farmers of the last century were unacquainted. Such an enquirer will feel assured, after viewing even in the Wandle valley many other good efforts besides the steam plough, that there are as yet no symptoms of agriculture having attained its culminating point.

WEEDS AND WEEDING.

The season is at hand when every good farmer is keeping a close over-sight upon the various weeds which infest the crops of his farm, and the land he is fallowing. It is a very important season to a cleanly farmer, and he is often sorely perplexed as to the best means to adopt for eradicating these pests to good cultivation. His first aim will be to clean his fallows; and the greatest pests he finds there are root-weeds, *i. e.*, twitch, docks, foal-foot, buttercups, cornbine, thistles, goose-grass or pignut, toadpipe, horse-mint, &c., &c., &c.; many of these roots are very tenacious of life, and will require his utmost attention and care to overcome their hardy habits and to destroy them. Their varieties are very numerous. The varieties in twitch alone have been stated to reach seventy-three distinct specimens; and the sorts vary in the size and strength of their roots, from the thickness of a tobacco-pipe to the fine thread-like sort, a short and almost interminable kind. The larger sorts may with tolerable facility be worked up to the surface, in fallowing, by a requisite number of scarifyings and harrowings, from whence they can easily be got off and burnt; but the finer varieties are with very great difficulty managed. The more you plough, scuffle, and harrrow, the more sets you make; and as every knot is a set, they soon strike in fine mould, and are so minute as to be almost undiscernible; and unless the weather is dry and sunny—indeed, so scorching hot as to injure vegetation—this kind can scarcely be got rid of. To effect this most desirable end, in fallowing the soils that produce this sort, it is necessary to keep it constantly stirred either by harrow or scarifier; the latter to be preferred. However, I am not speaking of the best mode of fallowing at this time, but of the eradication of weeds. The great end is to keep them on the surface in fallow time, so that the sun's scorching heat may dry them up. Docks, foal-foot, buttercups, thistles, pig-nut, horse-mint, toadpipe or mare's-tail, as also cornbine and hog-grass, have each hardy roots, and require the same kind of management to effect their destruction. The safest course, however, is to pick off most of these larger roots for burning; but the twitch may be better got off by raking, or by the use of the chain harrow. This is a comparatively new application of this implement; but in a dry season, and twitch being abundant, it is probably the best appliance for clearing the land we yet have had introduced. These harrows act in a double capacity—by pulverizing the surface, and at the same time rolling the twitch up into irregular collections of various sizes, and quite as clean as by the hand-rake. For rolling off the finer sorts of

twitch it is a very effective implement, and worthy the adoption of light-land farmers where such twitch abounds. Phillips' poppy extirpator may also be advantageously used in lightening up this sort of twitch, and freeing it from adhering soil. *Howards* and *Ransomes* have fitted these extirpating teeth to their horse-rakes, with every prospect of great usefulness in working, and of economy to the purchaser. A combined implement of this kind cannot fail to be advantageous, as it is brought into such general requisition upon the farm at different seasons. In the spring it is a poppy extirpator, in the summer a twitch and hay-rake, and in the autumn a stubble-rake.

I am well aware that good clay-land farmers are apt to scoff at twitch growers, and pronounce them to be bad farmers; be this as it may, it is still the great bane of every light-land farmer, and of not a few heavy-lands men. Much has been written upon the best modes of extirpating it, but to no great purpose; and so long as farmers will crop heavily (and why should they not?) they must expect a continuation of this pest. What steam cultivation may effect I cannot say, but with our present appliances I am without hope. The great thing at present is to keep it in subjection, so as not to allow it to injure any growing crop. The introduction of steam culture will enable us to work our lands when our horses are in full requisition in harvest and other work, which is one great means to this desirable end; and much good will unquestionably arise, leading to a further extension of our rotations in cropping: but the pest still remains. I will, therefore, offer a few observations or suggestions as to the most effective mode of subduing or suppressing it. The first attack should commence immediately after the corn is cut. Wherever there is a plant or bed of twitch, it should be broken up either by fork or other more powerful implement. The deeper the better, so as to reach the bottom of the roots: the further spreading will thus be prevented. As soon as opportunity serves, and the season is suitable, it should be worked to the surface and be picked off. Another excellent mode is to have all the green crops—the fallow crops—looked over in the autumn, and have every plant of twitch forked up and carried off: this is taking the young plant before it has time to gain much strength and spread its roots, "nipping it in the bud." The broad-clover crops ought also to be looked over, and every stray plant should be extracted. Every hedge-row should be cleansed during the winter, so that neither roots nor ripened seeds should be permitted to propagate their stock; finally, never let a plant of twitch stand unmolested on any part of the farm where it can be got at without damaging the crop.

As preventives, never sow any grass seeds containing the seeds of twitch: this is one of the worst and most pernicious things done by a farmer in the whole course of his business, and is the great nursery of twitch. A thorough determination to avoid this at all hazards would ultimately cause the growers of rye-grass seeds to be more cautious. Cheap grass seeds are notorious intermixtures, and certain propagators of twitch. Meadow-grass seeds abound in twitch seeds, &c. Once in every summer at least, cleanse out or "*rode*" every ditch, and do not permit the ditch-side grasses to ripen their seeds, so that birds and stormy winds may carry and deposit them over the lands adjoining. Hedgerows should also be looked over in July or August, and the detrimental grasses growing here should be cut down. Constant laborious attention will be ever needed to rid the farm of this most obnoxious enemy, and no opportunity should be lost whenever the land is clear, and in a state to be worked. It is by long courses of cropping, by delayed cultivation, or in resting the soil, that much increase takes place. Let every farmer pay due attention to these minor points, and then he will have the satisfaction to cultivate a cleanly farm.

THE GROWTH OF BARLEY BY DIFFERENT MANURES CONTINUOUSLY ON THE SAME LAND, AND THE POSITION OF THE CROP IN ROTATION.

By J. B. Lawes, F.R.S., F.C.S., and Dr. J. H. Gilbert, F.C.S.

The original paper under this title, of which the following is an abstract, occupies nearly eighty pages of the last number of the *Journal* of the Royal Agricultural Society of England (vol. xviii., part ii. pp. 454—531). The results of extensive series of experiments are there given, in much detail, in the tabular form. It is proposed to give here only an outline of the plan of the experiments, and an abstract of the conclusions arrived at, with but little numerical detail. A main object of the inquiry was to ascertain the characteristic manuring required for full crops of barley as grown in our rotations. The results of three separate sets of experiments are brought to bear on the question; and others, of an earlier date (1845), had given results consistent with those now more fully considered. In the first set of the newer series the crop was grown, after two previous corn-crops, for six successive years on the same land with different descriptions of manure, the same being applied to the same plot each year. One or two plots were always without manure, one with farm-yard manure, some with purely mineral manures, some with ammoniacal salts alone, some with nitrate of soda alone, some with rape-cake alone, and some with mixtures of both the mineral and nitrogenous manures; in all, making about twenty experiments each year. In a second field, barley was grown for three years in succession, without manure, after ten successive crops of turnips, which on some of the plots had had no manure, on others mineral manures alone, on others mineral and nitrogenous manures, and so on. In a third field, barley was grown experi-

mentally in the ordinary rotation of turnips, barley, clover (or other leguminous crop), and wheat. In the rotation experiments one plot was entirely unmanured throughout each course; a second had superphosphate of lime only, and this for the root crop alone; and a third was well manured with mineral, nitrogenous, and carbonaceous manure, for the roots commencing each course. The produce of the barley of three successive courses of each of these differently manured rotations has been recorded.

The experiments on the successive growth of barley on the same land with different manures come first under consideration. And the point relating to them to be first noticed is the very varyin result obtained with one and the same manure, in the six different seasons (1852—7) in which the trials were made. On this point it is remarked—

"From the pervading influence of *season*, by which the produce may be double as much one year as another, even with one and the same set of conditions supplied by the farmer, and by which, when unfavourable, the crops most highly manured suffer most, it results that the amount of produce obtained for a given outlay in manure may be only half as much in some seasons as in others." It resulted, too, that the higher the condition of manuring, if beyond a somewhat even narrow limit, the less was the proportional return of produce for a given quantity of manure.

Referring to the effects of the different *manures*, notes taken in the field showed, that the crops grown on the unmanured, and on the only mineral-manured plots, as a rule stood up till the time of cutting. Those having nitrogen in manure equal to about 50lbs of ammonia per acre per annum (supplied by 200lbs. of salts of ammonia,* or 275lbs. nitrate of sodat), were generally, more or less laid; as also were those grown by farmyard manure. Those having double this amount of nitrogen in the manure, or more (supplied by 400lbs. ammoniacal salts, 550lbs. of nitrate of soda, or in 2,000lbs. rape-cake), were invariably laid, and in most years very much and injuriously so. The produce with this latter amount of manure was in fact far too heavy to bear any moderate amount of rain about or after the time of heading. Of the mineral manures used, the "*mixed alkalies*," which consisted of a mixture of the sulphates of potash, soda, and magnesia, whether alone or in admixture with nitrogenous manures, invariably tended to retard the ripening of the crop. Superphosphate of lime, on the other hand, always tended to early ripening. The superphosphate of lime also always gave a notable increase of crop, whether it was used alone, in admixture with other mineral manures, or with nitrogenous manures. The nitrogenous manures, however, increased the produce in a far greater degree than any of the purely mineral combinations.

In the following table is given a summary of the numerical results obtained, showing the average annual produce taken over the six years of the experiments, by each characteristic description of manure employed:

ABSTRACT OF RESULTS OF EXPERIMENTS ON THE GROWTH OF BARLEY BY DIFFERENT MANURES, DURING SIX CONSECUTIVE YEARS ON THE SAME LAND, 1852, '3, '4, '5, '6, AND '7.—HOOS FIELD, ROTHAMSTED, HERTS.

Nos.	Manures—Quantities per acre per annum.	Average Annual Produce per acre.				
		Dressed Corn.		Total Corn.	Straw and Chaff.	Total Produce (Corn and Straw).
		Quantity.	Weight per bushel.			
		Bush. pecks.	lbs. & tenths.	lbs.	lbs.	lbs.
1	Farm-yarm manure, 14 tons	43 0¾	52·0	2,407	2,790	5,197
2	No manure	28 0	51·9	1,585	1,760	3,345
3	Mineral manures, only (mean of 3 plots)	31 2¾	51·9	1,763	1,885	3,643
4	275 lbs. nitrate of soda, alone (containing nitrogen = about 50 lbs. ammonia)	42 0¼	51·9	2,364	2,862	5,226
5	100 lbs. each sulphate and muriate ammonia, alone (containing nitrogen = about 50 lbs. ammonia)	38 2½	51·5	2,191	2,538	4,729
6	100 lbs. each sulphate and muriate ammonia (containing nitrogen = about 50 lbs. ammonia), and mineral manures in addition (mean of 3 plots)	43 3½	51·8	2,471	3,075	5,546
7	550 lbs. nitrate of soda, alone (containing nitrogen = about 100 lbs. ammonia)	47 3¾	50·9	2,666	3,532	6,198
8	200 lbs. each sulphate and muriate ammonia, alone (containing nitrogen = about 100 lbs. ammonia)	46 0	50·7	2,603	3,191	5,794
9	200 lbs. each sulphate and muriate ammonia (containing nitrogen = about 100 lbs. ammonia), and mineral manures in addition (mean of 3 plots)	47 3	50·6	2,672	3,733	6,405
10	2000 lbs. rape-cake, alone (containing nitrogen = more than 100 lbs. ammonia)	48 0¾	50·9	2,664	3,548	6,212
11	2000 lbs. rape-cake (containing nitrogen = more than 100 lbs. ammonia), and mineral manures in addition (mean of 3 plots)	46 3	51·0	2,613	3,553	6,166

From a review of the whole of the results relating to the action of the special manures upon the barley crop, taking the average of six successive years of growth by each, on land in an agricultural sense somewhat ex-

* An equal mixture of the sulphate and muriate of ammonia of commerce.

† The commercial nitrate of soda.

hausted for corn-growth, the following conclusions are arrived at :

"That exclusively mineral manures, and especially those containing phosphoric acid, annually increased the produce of barley; even doing so in the first year of their application on land in the condition described."

"That with barley grown continuously on the same land (as was the case with wheat), nitrogenous manures had a much more striking effect than mineral manures."

"That by the annual supply of nitrogenous manures alone (nitrate of soda or ammoniacal salts), larger successive crops both of corn and straw were obtained, than by the annual use of 14 tons of farmyard manure, with all its minerals, and certainly more nitrogen than either the nitrate or ammoniacal salts employed by its side."

"That within certain limits, even on this comparatively exhausted soil (and it would probably be more nearly so on soils in ordinary condition for the crop), nitrate of soda, ammoniacal salts, and rape-cake, all increase the produce of barley, approximately in proportion to the amounts of nitrogen they respectively supplied. Their comparative effects will, however, vary somewhat according to season, the nitrate being generally more rapid in its action."

"That to obtain a maximum amount of increase in proportion to the nitrogen given in manure, the barley crop will, on the average of seasons, bear a considerably less acreage amount of it than is required by the wheat crop under similar circumstances."

"That the effect of a given amount of nitrogen, if not excessive, will be considerably increased by the addition of certain mineral manures, especially those containing phosphates. The action of the mineral manures is very much increased under such circumstances; that is, their application gives very much more increase, when there is present a liberal supply of *available nitrogen within the soil*, than when there is not."

"In other words, a soil brought by previous cropping into a condition to require manure of some kind before it will grow a full crop of corn, when afterwards cropped year after year with barley, only yields full crops when a liberal amount of nitrogen is supplied to the soil. Mineral manures, especially phosphates, considerably increase the action of the nitrogen so supplied; but the effect of such mineral manures on the increase of crop will be extremely limited, without there be a liberal amount of *available nitrogen within the soil itself*."

The next set of experiments to be noticed, is that in which barley was taken successively from the same land in the seasons of 1853, '4, and '5, after ten successive crops of turnips, which had been grown experimentally, by different manures.

On one plot, the last seven of the ten preceding crops of turnips had been grown without any manure whatever; and this unmanured produce, leaf and bulb together, averaged little more than two tons per acre per annum. The second plot had received for the last eight of the ten crops of turnips liberal supplies of mineral constituents, mostly in much larger quantities than they were taken off in the root crops. Plot 3 had the same mineral manures for the turnips as plot 2, and, in addition, during the six middle years of the ten, about 44 lbs. of nitrogen per acre per annum in the form of ammoniacal salts. On the 4th plot there had been the same mineral manures as on plots 2 and 3, and an average annual addition, during six of the years of turnips, of about 95 lbs. of nitrogen per acre, in the form of rape-cake. The turnips on the 5th plot had received the same mineral manures as on plots 2, 3, and 4, and in addition, during six of the years, both the ammoniacal salts as on plot 3, and the rape-cake as on plot 4, which together gave an average annual supply of about 140 lbs. of nitrogen per acre.

The mineral-manured plot gave much larger crops of turnips than the unmanured one; and the addition of nitrogen, and other organic constituents of manure, as on plots 3, 4, and 5, always afforded a further increment of increase. But in neither of the three cases was the nitrogen recovered in the increased produce of the turnips equal to that which was supplied in the manure. It might be expected therefore that where nitrogen was supplied for the turnips—unless it were evaporated or drained in some form from the soil, distributed too widely throughout it, fixed in it in an unavailable condition of combination, or in some way dissipated during the growth of the plant—that there would be some remaining available for the three succeeding crops of barley. The discussion of the results of the three years' growth of barley, after the ten differently manured turnip crops, is prefaced as follows:—

"If the characteristic influence of a *rotation of crops*, upon the increased growth of the cereals, be at all materially due to the elaboration in the soil, during the growth of the other crops, of the necessary mineral supplies for the white crop, it might surely be expected that here, after ten meagre, unmanured crops of turnips, appropriating no amount of silicates, we should have, if ever it were possible, a large produce of barley, depending, with these rich stores of prepared mineral food in the soil, upon atmospheric sources for its nitrogen? If not after the many crops of *unmanured* turnips, surely after those provided with a very large excess of other mineral matters than silicates—the crop taking none of the latter out—we should have enough elaborated and conserved in the soil both of these and of all other mineral constituents, to yield the fullest crop of barley which it is possible to obtain by the conjoint influence of a very rich mineral condition of soil, and the normal season supplies of available nitrogen?"

But the result was that, comparing the produce of barley after the unmanured turnips with the unmanured produce during the same three years, in the field devoted to the continuous growth of the crop by different manures, the turnip land gave an average annual produce of not quite 19 bushels of corn, and the continuous barley field nearly 32 bushels. The amount of straw, too, was only about two-thirds as much after the ten crops of turnips as in the field whence so much more corn had been recently taken. In fact, a produce of

scarcely 19 bushels per acre per annum of barley corn, and little more than half a ton of straw—together, equal to not a ton of dry substance of produce—will be admitted to be exceedingly small. The conclusion was, that the *condition* of the land, after ten successive crops of turnips had been removed, must have been, for barley growth, at the lowest possible point.

"That a liberal supply of mineral constituents distributed through the soil cannot restore this exhausted fertility is seen by the produce of barley after the mineral-manured turnips. After ten years of turnips, the last eight of which were grown by excessive supplies of mineral manures, we have an annual average of 54lbs., or 1 bushel of corn more, and 79lbs. of straw less, equal to 25lbs. *less total produce*, than after the unmanured turnips."

The question is then—"In what constituent, or constituents, had these unmanured and mineral-manured turnips exhausted the soil, in so far as the after production of barley was concerned, to a point even far below that arrived at in the other field by the previous growth of one crop of wheat, one crop of barley with sulphate of ammonia, and one crop unmanured—that is, three white-straw crops in succession without mineral manure?"

A comparison of the produce of barley on the plots where the turnips had been manured with nitrogenous as well as mineral manures, with that where they had received mineral manures alone, throws some light on this point. Thus, where ammoniacal salts as well as mineral manures had been supplied to the turnips, the succeeding barley gave an average annual increase of about 2 bushels, or 102lbs., of corn, and 94lbs. straw, over the produce where the mineral manures alone had been applied. Where, in the rapecake, a larger amount of nitrogen had been supplied to the turnips, there was an average annual increase in the barley crop of 5¾ bushels of dressed corn, or 333lbs. total corn, and 381lbs. of straw. Lastly, where during six out of the ten years of turnips their manure (in the form of both ammoniacal salts and rapecake) supplied a still larger amount of nitrogen, in addition to the mineral manures, the succeeding barley gave an average annual increase of nearly 5¾ bushels of dressed corn, or 315lbs. total corn, and 331lbs. of straw, over the produce where there had been mineral manures alone.

"We had then, with a residue in the soil of merely mineral manures, even a loss of produce of barley—due to a greater growth, and consequent greater exhaustion of other matters, by the turnip. We find, on the other hand, a perceptible gain in the barley wherever the turnips had received either ammoniacal salts or rapecake as well as the mineral manures. Even here, however, the produce, with this nitrogenous and full mineral residue in the soil, was not equal to the annual unmanured produce in the other field, where the barley was growing continuously."

"That the beneficial effect of the residue of the rapecake was not due to the mineral constituents it supplied, may be judged by the fact, that the residue of the direct mineral manures had not any such effect. It was undoubtedly a residue of *available nitrogen within the soil*, that gave the increase of produce of barley where the ammoniacal salts or rape-cake had been employed for the turnips. If this be admitted, we have in the facts at once a beautiful illustration of the degree of reliance upon nitrogen in the soil, of the turnip crop, and of the utter incapability of rich supplies of mineral constituents in the soil, to be of any avail in yielding agricultural quantities of barley, unless there be at the same time *within the soil* a liberal amount of *available nitrogen*."

If further proof be wanted that the necessary mineral constituents were in abundance, and available in this turnip-exhausted soil for very full crops of barley, provided only available nitrogen were also within the reach of the roots of the plants, it is to be found in the results of experiments, in which, in one of the three years of barley after turnips, one portion of the plot, where the residue of the turnip mineral-manures alone had been unavailing to increase the produce of barley, now received about 82lbs. of nitrogen in the form of ammoniacal salts, and another portion about the same amount of nitrogen in nitrate of soda. They were as follows:

"In 1854, those portions of the mineral-manured plots left without further manure gave 19½ bushels. But where now (in 1854), about 82lbs. of nitrogen per acre were added as ammoniacal salts,* we had, instead of 19½ bushels, 52½ bushels of barley; and where the same quantity of nitrogen was added as nitrate of soda,† 54¾ bushels. The increase in the produce of straw was in greater proportion still. By the addition of the ammoniacal salts, the straw was raised from 1,397lbs. per acre to 4,379lbs.; and by the nitrate of soda it was increased to 4,781lbs. The total produce (corn and straw together), was thus from 3 to 3½ times as great by the simple addition of ammoniacal salts or nitrate of soda." And it may be observed, in passing, that here, as has been noticed in other cases, the nitrate of soda was more active than a quantity of ammoniacal salts containing an assumed equal amount of nitrogen.

"It is very remarkable too, that although the produce after the mineral-manured turnips was little more than half as much as the unmanured produce in the field of continuous barley experiments, yet the addition of a given amount of nitrogen gave very nearly identical results in both fields. Thus, after the mineral-manured turnips, we had, with the ammonaical salts and nitrate of soda respectively, 7,377lbs. and 8,005lbs. of total produce (corn and straw together); and in the field of continuous barley experiments we had, with the same amount of nitrogen, given as ammoniacal salts (without minerals), 7,548lbs., and as nitrate of soda (second year without minerals), 7,400lbs. of total produce. Again, in the same field of continuous barley experiments, the mean result of direct mineral manures and ammoniacal salts together, was 8,320lbs.; and that of even more nitrogen given as rape-cake (itself supplying also mineral constituents, as well as carbonaceous

* 200lbs. sulphate and 200lbs. muriate of ammonia of commerce.

† 550lbs. commercial nitrate of soda.

organic matter), with, in three out of four cases, direct mineral manures also, was 8,150lbs."

"In the contrasts and coincidences afforded by the results in these two fields, we have the clearest evidence that it was in *available nitrogen* for the barley crop that the previously mineral-manured turnip soil had become deficient, as compared with the unmanured land in the field of continuous barley experiments. It is evident, moreover, that on the mineral-manured turnip plots there was an abundant provision of the requisite mineral constituents for an exceedingly full crop, within the reach of the barley plant, provided only *available nitrogen* were also within the reach of its roots. Lastly, with the widely differing condition of the land in the two fields without further nitrogenous manure, and the approximation to equal amounts of produce when with comparable other conditions, both are supplied with a full dressing of such manure, again we learn how marked is the influence of season on the productive effects of our most active manures."

With the further light upon the "*condition*" of soil required by the barley crop, which the examination of the produce obtained after ten years of turnips, and its comparison with that in the other field, affords, the results obtained in still another field, under circumstances differing widely from either of the other two, are next to be considered.

In 1848, three portions, of nearly an acre each, were set apart for separate experiments on the chemical statistics of *rotations of crops*. For all three of these portions of land, the rotation chosen was—turnips, barley, clover, wheat. As was to be expected, however, the clover, coming round after a lapse of only four years, failed; hence, in the second and third courses, half of each plot was sown with beans, and the other half fallowed, instead of the clover. None of the crops were manured, excepting the turnips.

The plot of rotation No. 1 remained entirely unmanured—even the turnips—course after course.

The turnips of rotation No. 2 were manured, each time they came round, with superphosphate of lime alone.

The turnips of the third plot (rotation No. 3) were manured, each course, with superphosphate of lime, the sulphates of potash, soda, and magnesia, 2,000lbs. rape-cake, and 100lbs. each sulphate and muriate of ammonia, per acre.

There were, therefore, three parallel rotations with the same crops; one of these had no manure whatever, course after course; the second had superphosphate of lime alone, once in four years; and the third, after the same interval, received a mixed manure, supplying liberally to the soil phosphates and other mineral constituents, and both nitrogen and carbonaceous organic substance.

In each of the three four-course rotations, barley has been taken three times—namely, in 1849, in 1853, and in 1857; and, as from half of each turnip-plot the entire produce, leaf and bulb, was carted-off, and on the other half the roots were eaten by sheep, and the leaves distributed over the land, the produce of the barley on each turnip-plot was so subdivided, as to show the comparative effects of the drawing-off and folding. The turnips on the continuously unmanured plot averaged only from 4 to 4½ tons per acre, per course, leaf and bulb together; the superphosphated turnips from 13 to 14 tons; and those by the full mixed manure, over 20 tons.

The result was, that the produce of barley obtained in *rotation*, even when the turnips were both unmanured and carted-off, was considerably greater than when, as in the field first described, the crop was grown annually in succession on the same land, without manure. This was even more strikingly the case in the third unmanured rotation-course than previously. And it will be remembered that the barley grown continuously in succession was, in its turn, considerably more than that after the series of unmanured turnip-crops as in the second field considered. Consistently with this last point, the produce of barley in *rotation* was considerably less after those *carted-off* turnips which were grown by superphosphate of lime, than after those grown without any manure whatever. This is explained by the fact that much larger crops of turnips were taken from the superphosphated than from the unmanured land. On the other hand, as was to be expected, the *fed superphosphated* turnips gave larger succeeding crops of barley than the *fed unmanured* ones.

On the unmanured rotation-land, the folding of the meagre crops of turnips did not increase the produce of barley. On both the superphosphated and the mixed-manured rotation-plots, the folding of the turnips did much increase the produce of barley. The difference in the amount of barley after the folding, compared with that after the carting off of the turnips, was greatest on the *superphosphated* plot; in which case the exhaustion of the land by the *removal* of the turnips was the greatest, and the manuring from the *folding* was not too high. In fact, on the highly manured rotation-plot, the land after the removal of the turnips was still left in good condition, and after the folding in too high a one for the barley to stand the vicissitudes of season—under which it was the more liable to injury when manured beyond a somewhat limited degree.

It will now be interesting, for a moment, to review as a whole, the various field experiments on the growth of barley.

"It has been found, that the amount of produce when grown after a succession of removed unmanured, or even highly mineral-manured turnip crops, was far below a moderate agricultural yield. It was seen that by the simple addition of nitrogenous manure to land in this condition, enormous crops were raised. When barley was grown without manure year after year, on land in a less artificially exhausted condition than that where ten successive turnip crops had been grown, the produce was considerably greater than after the succession of turnip crops. On this land mineral manures somewhat increased the produce. But, as on the turnip exhausted land, nitrogenous manures did so

much more strikingly. In both fields, indeed, the amount of available nitrogen supplied to the soil ruled the amount of produce very much more strikingly than did the supply of the necessary mineral constituents of the crop. In growing barley in *rotation*, on land previously brought to that comparative state of exhaustion, in which, under ordinary cultivation with home manuring and ordinary cropping, the conclusion of a course will leave it, the unmanured produce of barley throughout three subsequent courses of an entirely unmanured rotation was considerably greater than that where barley was grown year after year; and it was still further in excess of that obtained after a series of unmanured turnip crops."

"Here then is a striking effect upon the produce of barley by growing it in a *rotation*—even unmanured—of turnips, barley, clover, wheat. When the turnips in such a rotation were grown by superphosphate of lime, and by it larger crops of the roots removed than without manure, the produce of barley was less than after the unmanured turnips. Here too, then, the produce of barley is diminished after unusual exhaustion by turnip-cropping. But either the consumption of the superphosphated turnips on the land, the residue of a mixed mineral and nitrogenous manure after turnips grown by it had been carted off, or the consumption of these turnips on the land, greatly increased the subsequent produce of barley above that of the turnip-exhausted rotation land. It could certainly not be the restoration of mineral matters, to which, in these cases the increased produce of barley was mainly due; for the increase was greater by the consumption on the land of the merely superphosphated turnips, than by the residue of far richer mineral (and organic) manure where the turnips grown by it had been removed, taking away but a small proportion of the supplied minerals; and it was greater still where these highly-manured turnips were fed on the land, and returned to it a considerable amount of nitrogen, in addition to the already relative excessive amount of minerals. It was seen too, in the other fields, that mineral manures were quite unavailing to give even moderate crops of barley, unless there were *available nitrogen within the soil.*"

"It may be fairly concluded that a characteristic effect of alternating the other crops with the barley, has been to leave more available nitrogen from some source, within the reach of the roots of the latter, than when either this same crop was grown continuously in succession, or when a number of successive turnip-crops were previously removed from the land. Barley then, like wheat, requires characteristically what may be termed a nitrogenous *condition* of soil. It cannot, however, under ordinary circumstances, bear such large amounts of nitrogen supplied as wheat; though what it does require, from the habit of the plant, and its usual limited period of growth, should be more confined to the upper layers of soil. For these reasons, barley may often be taken with advantage after a previous white crop, by a spring dressing merely, of chiefly nitrogenous manure. In such cases the direct addition of mineral manures, especially those containing phosphates, will have a more striking effect than upon the *winter-sown wheat*. The effect of such mineral manures is not only to increase the general growth, but to bring the crop more rapidly to maturity. The more frequent alternative is, that barley is taken after a root-crop, in part or entirely fed on the land. The appropriateness of this course for barley rather than for wheat, besides the advantage arising from the season of the year at which the land is generally clear for the corn, rests mainly on the fact, that the manure by folding, with the subsequent light working of the land, is more confined to the superficial layers of soil, in which, comparatively, the roots of the barley play more freely.

"A disadvantage of growing barley after the folding of sheep on turnips is, that with high farming the land is apt to be thus left in too high a condition for the crop to succeed well in the average of seasons; whilst, on the heavier lands, there is frequently much injury done to the texture, rendering it difficult to get the fine tilth so essential to the favourable growth of barley.

"Of direct portable manures for barley, Peruvian guano, or salts of ammonia, or nitrate of soda—either of them with a small quantity of superphosphate of lime—are the best. Rape-cake is also a good manure for barley, but it is generally too high in relative price. These manures, as well as purely mineral manures, are most advantageously applied before, or at the time of sowing, so as to be somewhat distributed through the surface soil by the mechanical operations. As a mere top-dressing nitrate of soda is the best. Of the more exclusively nitrogenous manures—salts of ammonia and nitrate of soda—the nitrate acts somewhat more rapidly for a given amount of nitrogen supplied. The action of the purely nitrogenous manures is economised by admixture with a small quantity of superphosphate of lime, or other appropriate mineral manure. Other things being equal, the later the barley is sown, the less should be the proportion of nitrogen in the manure, and the greater that of mineral constituents; otherwise the crop is liable to be too luxuriant; and with a limited range of root in the soil, it will probably not find mineral constituents rapidly enough in the later stages of growth, for a favourable development and maturing of the seed."

Some additional remarks are here appropriate, on the observed more marked effects of direct mineral manures on the *barley* than on the *wheat* crop. A consideration of the distinctive habits and usual circumstances of growth in our rotations, of these two nevertheless much allied crops will be found to throw some light on the point alluded to.

The necessity of considering the various habits and conformation of the different crops of our rotations in relation to their resources of growth was prominently insisted upon in previous papers, in the *Journal of the Royal Agricultural Society*, more than ten years ago. Such considerations, the bearings of which are among the first lessons taught by the progress of field experiments, tend materially to modify the conclusions to which a more purely chemical view of the offices and province of the various constituents in a system of

manuring would lead. In order to verify and define the more obvious conclusions of superficial observation on some of the points here in question, the summer of 1846 was mainly devoted to the examination of the comparative underground ranges of the various crops of our rotations. In reference to the results of the experiments then made, it may be mentioned, that the relatively great depth and extent to which several of the leguminous crops, and also wheat and oats, penetrated, were very remarkable. In defect of drawings of the specimens then traced out, rough sketches taken in the case of some recent experiments, in which, with another object in view, wheat and barley had been grown side by side, under somewhat artificial conditions, in pots, illustrated the strikingly different distribution of the roots of these two plants. The barley threw only a single fibrile to the bottom of the pot. The wheat, on the other hand, sent out such a mass of ramifications, that the whole of the surface of the dish in which its pot rested was covered with a thick net-work of roots; as also was the bottom, and, to a great extent, the sides of the inside of the pot itself. The contrast here manifested is, indeed, pretty characteristic of the two plants as grown in our fields.

Further on this point:—"When considering the results of field experiments on wheat, we have directed attention to the fact, that the success of the autumn-sown crop was greatly dependent upon the progress of the under-ground development during the early months of growth. It was held that this was very much favoured, other things being equal, by a liberal supply of available nitrogen within the soil, and that thus, the range of collection of the fibrous feeders of the plant was so extended as to render available, when needed in the after-stages of growth of the plant, the mineral constituents of a much larger area of the soil than otherwise would be the case. Very different are the usual conditions of the growth of barley. Instead of winter-growth, and a compressed soil, tending to increased depth and area of root-distribution, we sow our barley in the spring, work the staple shallow, and keep it as light and open as possible. Under these circumstances of short time, rapid growth, and comparatively limited depth and area of root-development, we find the direct supply of some of the rarer, but essential mineral constituents of our soils, much more efficient with the barley crop than with wheat.

"The mechanical conditions of soil, and the season of growth of the barley crop, are in many respects more like those required by the turnip; and they are calculated to favour the distribution of a large amount of fibrous root near the surface, rather than any considerable development in the lower layers. In our paper on 'Turnip Culture,'* it was shown how much this distribution of surface root-fibres was increased by the use of superphosphate of lime. The same is the case with barley. It is obvious, that with this multiplication and more thickly-distributed net-work of root-fibres, the greater must be the resources of the plant within its comparatively limited period and area of growth. Thus it is, that the increased supply of certain important constituents within a limited area, enables the plant to provide itself more freely and rapidly with others it may require." Again—

"Still referring to the action and province of mineral manures applied to our crops grown on cultivated land, it has been shown on former occasions that, in a soil brought to what may be termed a condition of *agricultural* exhaustion—that is, at the end of a rotation, when in the ordinary course of things it would receive manure of some kind—the autumn-sown wheat was not increased in produce by the *direct* application of mineral manures, until so many crops had been taken from the land as to exhaust it of mineral constituents more than would happen under nearly a century of ordinary rotation and home-manuring. It has now been shown, that a very similar soil, certainly not more exhausted in an agricultural sense, gave an increase in the produce of *barley*, even on the first year's application of mineral manures. Collateral experiments in the same field, as well as those in other fields of very different, yet to a certain extent known history of relative exhaustion or fertility, showed, however, that mineral manures were competent to yield, under these conditions of agricultural exhaustion, but a small amount of increase when compared with that obtained by nitrogenous manures. The evidence has also led to the conclusion, that the mineral manures, if at all, yielded increase in an extremely limited degree, unless there were available nitrogen accumulated by some means *within the soil*; in fact, that the increase of produce, other things being equal, was more in proportion to such available nitrogen within the soil, than to any other supplied condition. It has, however, recently been maintained in the Journal of the Royal Agricultural Society, that our characteristic nitrogenous manures cannot be said to be active in proportion to the nitrogen they contain."

In the paper referred to,* Baron Liebig states, that ammonia alone, or nitric acid alone, has never been used in agricultural experiments. His conclusion is, that the acids in combination with ammonia in ammoniacal salts, and the bases in combination with nitric acid in the nitrates, have had their share in the results obtained by the use of these salts. He also further quotes experimental evidence to show, that the value of manures cannot depend upon the amount of their nitrogen, but must depend upon the substances combined with the nitrogen.

In regard to the first mentioned statement, which was one of fact, it might be observed, that the results of experiments made at Rothamsted had been published, in which ammonia in combination with only *carbonic* acid had been employed. Mr. Pusey had also given the results of trials, in which nitric acid, soda, and potash, were each separately applied to grass. Of these results Mr. Pusey said: "In both trials the nitric acid acted decidedly. The alkalies, neither of them produced even a trace of effect on the colour or on the growth of the grass." And again, "The question being whether in saltpetre the alkalies or the acid contain the active principle, we have found upon a given soil the alkalies

* Journal of the Royal Agricultural Society, vol. viii., 1847.

* Ibid, vol. xvii., part 1.

absolutely inoperative, while the acid has acted exactly like saltpetre itself and like ammonia."

As to the general question here at issue, "it cannot for a moment be denied that the state of combination of the nitrogen in our nitrogenous manures, or their admixture with other substances, has some share of influence on the result. We have clearly shown that they have an influence, fluctuating according to season, exhaustion, amount employed, and other circumstances. It is, however, entirely inadmissible to attempt to draw any conclusions as to the influence of the state of combination of the nitrogen, or of the effect of substances supplied with it, from the comparison of the results of experiments in which unequal quantities of nitrogen are employed to a given area, or which were made indiscriminately in the same or in different seasons. Every one, at all conversant with field experiments, will have been early impressed with the very varying proportional effect from one and the same manure, if used in different quantities in the same season, in even equal quantities in different seasons, and above all, in unequal quantities in different seasons. But Baron Liebig founds his arguments upon the influence of the varying chemical combination of nitrogen, and upon the comparative effects of ammoniacal salts used *alone*, or in admixture with other constituents, upon experiments with nitrogen in these different states, made indiscriminately with different quantities of nitrogen to a given area, and in different seasons."

M. Kuhlmann indeed, upon whose results Baron Liebig founds his arguments, called particular attention to the influence of the various seasons in which his experiments were made. The following statement must further show, that the experiments cited were quite incomparable on the point in question. Thus, Baron Liebig compares with one another the results of about 70lbs. of nitrogen to a given area in the form of sal-ammoniac *alone* in *one year* (1843); of about 176 parts in the form of sal-ammoniac *with phosphates*, applied partly in 1844 and partly in 1846 and the increase of produce taken over the three years, 1844, '5, and '6; and of about 115 parts of nitrogen in the form of guano applied only in one year (1844), and the increase taken over that and two succeeding years; and upon the comparison thus made, he founds conclusions as to the effects of the different states of combination of the nitrogen in the manures, or on that of its admixture with other constituents. But, besides the experiments above alluded to, in which Kuhlmann applied about 15 parts of nitrogen to a given area in the form of guano, he made another, side by side, with the same guano, but with double the quantity, yielding therefore 30 parts of nitrogen to the same area. The result was, that where the smaller quantity of nitrogen was used, 72 per cent. more increase was obtained for a given amount of nitrogen than with the larger; yet, it was the action of the smaller quantity of guano applied in one year, and acting over three, which Baron Liebig selects to contrast with the large amount of nitrogen applied in different seasons in other manures, attributing the difference in result to the action of the associated mineral constituents in the guano. In another of Baron Liebig's illustrations on the same point, although 74½lbs. *more nitrogen* were supplied *with phosphates* than were given without them, he attributes the increase of produce in the one case over that in the other, to the addition of the phosphates.

Further, Baron Liebig explains the efficacy of a *fresh* supply of salts of ammonia, when a still unrecovered supposed residue of nitrogen from previous applications would be without effect, by supposing that the mineral constituents have been exhausted by the action of that portion *before* supplied which had been active, and that by the action of *fresh* salts fresh mineral constituents were set free from the soil, and thus the conditions restored for the supplied nitrogen to become effective. How far such an explanation is probably correct, may perhaps be judged of by the results which have been recorded on the growth of barley after ten years of turnips differently manured.

"During the growth of the ten turnip crops, some of the plots had received every year enormously more of all the mineral constituents of the barley crop, except silica, than the turnips removed. The latter removed no silica. So that, besides the excess of other mineral constituents, there was an accumulation during ten years of available silica. Yet with all this unusual accumulation of the necessary mineral constituents, the residue of nitrogen unrecovered in the increase of turnip crop—amounting as it did in some cases to more than the largest dressing we ever applied in one year to a corn crop—gave us, where there was the largest amount thus unrecovered, during three successive years of barley, an average annual increase of only 5¾ bushels of corn, and between 300 and 400 lbs. of straw per acre. On the other hand, the addition of fresh nitrogen, in the form of salts of ammonia and nitrate of soda respectively, gave at once an increase of 33 and 35 bushels of corn, and 4,903 and 5,531 lbs. of straw. And although the addition of the fresh nitrogen in the form of ammoniacal salts yielded an increase of 33 bushels of corn and 4,903 lbs. of straw, which together would contain only about half the nitrogen supplied in the manure, yet the remaining half, notwithstanding the still enormous excess of previously supplied mineral constituents, gave in the succeeding year only 6¾ bushels increase of corn and 646 lbs. of straw. Are we then to conclude, that, under the circumstances stated, the supposed large residue of nitrogen supplied to the turnips, was inefficient only for the want of available minerals? and that the striking effects of the newly-supplied lesser amounts of nitrogen were chiefly due to the action of the acids of the ammoniacal salts and of the soda of the nitrate, in rendering available the otherwise locked up mineral constituents within the soil? The utter inefficiency of even a liberal *direct* supply of mineral constituents, to recover, in the second crop of wheat after nitrogenous manures, more than an insignificant proportion of the supplied nitrogen not recovered in the first, has been forcibly illustrated in a former paper."

By the concurrent testimony of field experiments of

very various kinds, the conclusion has been arrived at, that full crops of barley cannot be grown unless there be, by some means, available nitrogen provided within the soil. In practice it is frequently convenient to increase the produce of the barley crop by the direct application of portable nitrogenous manures. It is very desirable, therefore, both in a practical and scientific point of view, to have some means of judging what is the probable proportion of the nitrogen so supplied in manure which will, on the average, or under given circumstances, be recovered in the immediate or successive increase of crop obtained. The experimental evidence which has been collected bearing upon this point also throws some light upon the influence of season and manuring on the per-centage of nitrogen in the barley crop, and upon the amount of nitrogen obtained annually from a given area without manure.

Before speaking of the direct evidence which analysis has supplied in the case of the experiments on the growth of barley without and with nitrogenous manures, the evidence and reasoning of others as to the proportion of the nitrogen supplied in manure, which is recovered in the increase of produce obtained by its use, may be first briefly noticed. In his paper in the *Journal* of the Royal Agricultural Society of England, before referred to (vol. xvii. part 1), Baron Liebig deduces from Kuhlmann's experiments on *hay*, that when ammoniacal salts were used *alone*, there was an apparent loss of four-fifths or three-fourths of the nitrogen employed; but that, when *mineral constituents were also added*, there was no such loss, but a *gain* from natural sources. To show this *gain*, the instance is quoted in which Kuhlmann used about fifteen parts of nitrogen to a given area in the form of guano. Adopting the same mode of calculation, however, there would be a *deficiency*, instead of a gain of nitrogen in the increase of produce, where Kuhlmann applied it in the form of the very same guano, but in just double the quantity to a given area, as in the former instance. In another of Kuhlmann's experiments, too, where a still larger proportion of nitrogen was employed to a given area of land in the form of sal-ammoniac, but *mixed with phosphates*, there would be, still adopting Baron Liebig's mode of calculation, a loss of more than 56 per cent. of the supplied nitrogen. In fact, so far as the evidence and arguments adduced bore upon the question, it appeared that to attain the result of no deficiency of the supplied nitrogen in the increase, but a gain over that supplied in the manure, the farmer must employ it in quantity which, in a practical point of view, was quite insignificant. The real bearing of the evidence which Kuhlmann's experiments supply is not the question here. It is, too, hardly necessary to reiterate an assent as to the essentialness of a liberal supply of the necessary mineral constituents of our crops. It has been frequently shown in former papers, what, under an ordinary course of practical agriculture, with rotation, *as it is*, are the usual circumstances of the removal and return of the mineral constituents, and what the requirements for their direct supply.

The experiments of Kuhlmann above alluded to were made upon grass. The direct results to be now noticed have reference, as already intimated, to the experiments in which barley was grown for six consecutive years on the same land, by different manures, of which the same description was applied to the same plot throughout the six seasons. More than one hundred nitrogen determinations were made on the barley corn or straw, grown respectively with and without nitrogenous manures.

Referring briefly to the influence of varying season and manuring, upon the per-centage of nitrogen in the produce of barley, it appeared from the results of the few seasons over which the experiments extended, that, so far as the crops grown without nitrogenous manure were concerned (that is, those which ripened best), the tendency was to give the lower per-centage of nitrogen, the higher the character of the crop, and *vice versâ*. The same has been found to be the case with wheat; but, as with the latter, so with barley, the rule is not without exception; it seems only to apply, on the average, as our seasons go.

When comparing the produce of the different seasons, grown by *nitrogenous manure*, the rule just indicated is not so clearly borne out; but, as the influence of even the smaller amounts of the nitrogenous manures which were employed, was to produce over-luxuriance, and depreciate the proportion and the quality of the grain, that is, to be unfavourable to perfect maturation, the apparent exception was rather a confirmation of the assumption, that high maturation and low per-centage of nitrogen were generally, with the average of our seasons, coincident.

"That we should get the higher *qualities* of crop indicated with the lowest amounts of produce per acre, is perfectly consistent with the practically admitted fact, that the *sample*, particularly of barley, is, on the average, the better the smaller the amount of crop. This smaller amount of crop is coincident with the relative deficiency of available nitrogen within the soil; and, with this higher quality of sample obtained with a low relative provision of nitrogen in the soil, we have a tendency to low per-centage of nitrogen in the most valuable descriptions of the grain. But *quality* cannot in practice be bought at so great a sacrifice of *quantity*. And it is seen that, when we increase the *quantity of crop* by increasing the relative amount of available nitrogen in the soil, it is generally depreciated in the admitted characters of *quality*; and at the same time the per-centage of nitrogen is increased. Further, the tendency to diminished quality and increased per-centage of nitrogen on the one hand, with increased amount of crop on the other, would appear to be the greater, the more excessive the supply of nitrogen beyond that which in the average of seasons can yield a well-conditioned and healthily-ripened crop. Barley indeed, from its comparatively limited hold on the soil, and its small and weakly straw in proportion to the weight of corn it has to carry, is, so far as favourable ripening and good sample are concerned, more sensitive to vicissitudes of season and to high manuring than wheat; and it is with the greater variation in degree of maturation in the former than in the latter, in one and the same season, with different proportions of available nitrogen provided within the soil, that we have, at the same time, a greater variation in the *per-centage* of nitrogen in the produce depending on the manure employed." It would appear, too, that we cannot, keeping within the limit of healthily-matured full crops, increase the per-centage of nitrogen in our barley grain much above a comparatively low amount, as our seasons go.

The next point of interest is, as to the amount of nitrogen annually taken from the land in the produce, where none was supplied in manure. "The highest amount of nitrogen thus stored up from the unaided soil and season resources was in 1854—namely, 32¼lbs. per acre; the lowest amount was 17½lbs., in 1856; and the average annual yield, taking the mean of the six years, was about 28¾lbs. It may be mentioned, that this latter amount is more than that annually deposited in rain and other aqueous depositions, in the forms of ammonia and nitric acid. Investigation—of which there is at the present time much going on in reference to this subject—has still to determine the source or sources of this annual excess of assimilated nitrogen, beyond that supplied in the combined form, in the measured and analyzed aqueous depositions. Whether it be due to

exhaustion of previously-accumulated nitrogen in the soil, to direct condensation by the latter of the nitrogenous compounds occurring in the atmosphere, to the formation of ammonia or nitric acid within the soil at the moment of the evolution by chemical changes of certain elements in the nascent state, to the accumulation of combined nitrogen from the atmosphere by the plant itself, or to its assimilation of the free nitrogen of the atmosphere—whether, or in what proportion, these several possible sources may take part in the result, is as yet a great problem, open for solution."

With regard to the important point, of the proportion of the nitrogen supplied in the manure, which was recovered in the increase of barley corn and straw obtained by its use, the general result, omitting all reference to detail, may be very briefly stated. In the experiments in question, the analyses showed that, even when the nitrogen supplied in manure was the less excessive, scarcely 40 per cent. of it was recovered in the increase of produce, taking the average result of several consecutive years. In some of the individual years, there was nearly, or even over, 50 per cent. recovered—that is, when the tendency to corn was the highest; in others, there was less than 30 per cent. of the supplied nitrogen recovered in the increase of crop obtained.

"In thus speaking of the proportion of the supplied nitrogen recovered in the immediate increase of the barley crop, our form of statement must be understood as only representing the practical result, as measured by the difference between the amount of nitrogen in the produce with nitrogenous manures, and in that without them. It must be admitted that we have not the means of deciding whether or not the crop grown by nitrogenous manure has assimilated the same amount of nitrogen from other sources, as that grown without it. We cannot say, therefore, whether the soil has to render an account of more or less of nitrogen than that indicated by the column of the amounts unrecovered in the increase of crop. The proportion unrecovered in the immediate increase is, however, obviously very large. It may be supposed that this at first unrecovered amount is still available to after-crops. We may as alternatives assume, that a portion is locked up in the soil in a practically-unavailable form—that it passes into states of combination in which it can be drained away, or evaporated from the soil—or lastly, that in some form or other it is got rid of by the functional processes of the growing crop. The actual or relative amounts of the several influences, science is not yet able to determine."

"It is obvious that, at any rate, some of the apparent loss to immediate increase of the supplied nitrogen will be due to the unequal distribution of the manure, in relation to the under-ground feeders of the plant. If this were all, however, the unrecovered nitrogen in a first crop should be sooner or later available to those which follow. But one thing is certain, that, even taking together the increase in several immediately succeeding after-years, the *proportion* then recovered, of the previously unrecovered nitrogen, is very much less than the *proportion* of the whole supplied, which is recovered, in the year or years of its application. This is even the case when the provision of the necessary mineral constituents is very liberal. Indeed, a much less amount of nitrogen newly supplied in the form of salts of ammonia or nitrate of soda alone, will give a greater increase of produce than the larger amount of supposed residual nitrogen, with direct mineral manures in addition. It cannot well be supposed, therefore, that the amount of the supplied nitrogen unrecovered is simply due to its greater distribution, or the exhaustion of mineral constituents, though still remaining, so far as state of combination is concerned, *available*."

"As a fact in practical agriculture, it must be concluded, that the nitrogen supplied in manure for full crops of grain, is not recovered in the increase within any moderate period of time. We hope on an early occasion to add to the statistical results in this and in former papers on other crops, those relating to the proportion of nitrogen recovered in increase, to that supplied in manure for *grass*. But even with all the evidence which the facts of the field will be able to provide, the problem will still remain—of the exact explanations to be given by science, of the loss which is experienced by practice."

THE USE AND ABUSE OF ALUM IN BREAD-MAKING.

Every now and then, of late years more especially, we are terrified with some household cry. By some means or another we are found to be slowly, perhaps, but systematically killing ourselves. We are living over sewers; have heavy curtains to our beds; or arsenic-tinted papering to our rooms. We delight to season our food with condiments that are little less than rank poison; and cling to essences and sauces that, like the fox of the Spartan boy, are eating out our vitals. Even the plainest fare is not without its alloy. Water itself is declared to be impure; the best meat to be diseased; the finest bread "doctored," and the nicest beer drugged. It is not only Damocles in Grosvenor-place who sits down to dinner with this drawn sword of danger hanging over him. Tradesmen mutually return the compliment one on the other; while Hodge carves a crust that, if he did not bake it himself may be as much tampered with as anchovy paste or London porter.

Indeed, the sins of the baker are a very old story. There is scarcely a man but who knows too well how even the best bread is manufactured—how it comes to look so white, and so fine, and so "crummy." Like the state prisoner, who believes his doom is a secret death in his dungeon, he swallows every mouthful in fear and trembling. Most probably there is something wrong in it. Only when far removed from cities does he breathe again. Over the home-made heavy brown loaf of his country cousins can he eat, drink, and be merry. As he cuts the solid slice from off it, he ejaculates mentally, or may-be distinctly enough, "Ah! this is the thing; there is no alum here I can see." When Coleridge's taciturn friend greeted the dumplings as "Them's the jockies for I!" he had, no doubt, been suffering from an attack on baker's bread.

But after all, is alum this terrible curse we take it to be? Are we really justified—as happened ere now—on finding its presence in our quartern loaf, in rushing off to the baker's house, and pulling it, oven and all, about his ears? Or shall we, more reasonably, be content to indict him, and fine him, and ruin him? Dr. Odling, at a recent meeting of the Society of Arts, actually requests us to pause ere we do anything of the sort. In a paper he read some fortnight since, on the chemistry of bread-making, he discourses in this wise—He is speaking of some secondary varieties:—"But these flours, in proportion to their glucogenic tendencies, do not make good bread, and it becomes an object with

the baker to oppose the glucogenesis as much as possible. Hence, in making bread from certain kinds of flour, he finds it necessary to add alum, or lime, or bean-meal, or some corrective substance which, from experience, he knows will cause the flour to yield a loaf presentable to the eye and agreeable to the palate."

This has long been the popular, and, as it would appear, not erroneous opinion. It receives more confirmation a little further on:—"One very important use of alum is to prevent any undue deterioration of the starch during the process of raising and baking. If we mix a solution of starch with infusion of malt, in the course of a few minutes only the starch can be no longer detected, being completely converted into dextrine and sugar; but the addition of a very small quantity of alum either prevents altogether, or greatly retards, the transformation. The action of diastase upon undissolved starch is very gradual, but here also the interference of the alum is easily recognizable. Bread made with infusion of bran or infusion of malt is very sweet, sodden, brown-coloured, and so sticky as almost to bind the jaws together during its mastication. But the addition of alum to the dough causes the loaves to be white, dry, elastic, crumbly, and unobjectionable, both as to taste and appearance. I have found that flour, which of itself was so glucogenic as to yield bread undistinguishable from that made with infusion of malt, could, by the addition of alum, be made to furnish a white, dry, crumbly, eatable loaf."

The testimony of Liebig and Payen are both quoted to warrant the use of alum; and Dr. Odling thus sums up in favour of the practice:—"In the absence of any evidence, either from fair inference or direct observation, that the introduction of small quantities of alum into bread is prejudicial to health, it seems that the practice is not so reprehensible as is usually maintained. It certainly improves greatly the quality of bread made from inferior flour, and, in a politico-economical point of view, is important, inasmuch as it renders a large quantity of flour suitable for human food in the form of bread, which flour would otherwise have to be devoted to less important uses."

Still the doctor had it by no means all his own way. He rather takes it for granted that we really know of no ill effects arising from the use of alum. Dr. Snow, on the contrary, "had many years ago come to the conclusion that the practice of putting alum into bread was a fruitful source of rickets amongst children. It appeared to him that rickets were more prevalent amongst children in London and the south of England than was the case in the North or in Wales, where the children were just as overcrowded and as deficiently supplied with milk as in London. He believed that for grown people the admixture of a little alum was not very injurious, though for children it was so."

Then again, Mr. Pittard, "And many other medical practitioners had a settled belief that alum in bread was injurious to mankind. Sickly children had been found to improve marvellously upon baked flour, whilst they pined away upon soaked bread. The chemists spoke slightingly of the medical men because they did not pretend to know the chemistry of the question, and said that they were ignorant that the alum was decomposed in the making of bread. Even if that were so, it did not prove that the alum was rendered innocuous; if alum was resolved into alumina and sulphuric acid, he did not know whether alumina might not be injurious in the body. It was a fact worthy of note that, although alumina was one of the most plentiful substances on the earth, yet it did not enter into the composition of any organic bodies whatever, whether animal or vegetable. This alone was reason against the introduction of alum into food. With salt it was very different. They might be told that the chemical effects of alum on the animal system were not extraordinary, but there were chemical effects to be considered." Dr. Normanby, Mr. Varley, Mr. Johnstone, and Mr. Malone also spoke to the injury arising from the constant use of alum. But Dr. Gilbert "suspected the truth lay somewhere between the two extremes. He was not disposed to think that alum could be, with advantage to the consumer, added to really good flour, for the purpose of bread-making. On a large class of constitutions he thought there was medical testimony enough to show that alum, or alumina, in bread acted injuriously. With such it induced constipation, and this was a fruitful source of more serious disease. On the other hand, it was to be remembered, that owing to the seasons, which we could not control, a considerable portion of the flour, which must be consumed by somebody, was not in a perfect condition to yield a bread of good texture and other requisite characters without the aid of some extraneous matter; and if the bread were not of suitable texture and condition, its digestion would be imperfect, and if digestion, then assimilation also. The question was then, so far as related to alum, whether or not the benefits which it undoubtedly produced, so far as the physical and some other characters of the bread were concerned, were greater or less than the evils he believed it in many cases induced. The subject required much careful consideration; and if a substance or method that would have the same effects in retarding the chemical changes to be avoided in flour and bread, and which at the same time was undoubtedly innocuous, could be generally adopted, few would then uphold the use of alum. The suggestion of Dr. Odling to use lime-water, as recommended by Baron Liebig, was deserving the serious attention both of bakers and medical men." Mr. Dugald Campbell went more decidedly with the baker, and was "prepared to say that such a quantity of alum as would do an injury would render the bread unsaleable." And Mr. Callard, himself a baker, confirmed this:—"Dr. Snow had mentioned a quantity of alum as having been found in bread that he (Mr. Callard) could not suppose to be possible. Such bread could not possibly be eaten."

We regard the points of this discussion as not without interest, and we present them accordingly to our readers. The conclusion would seem to be that the evil has been greatly over-rated. It is very certain that some of the much-noised alum discoveries have been made upon tests anything but reliable. Dr. Odling characterized the means often employed as a disgrace to chemistry, and in showing up "the loose speculation," and "groundless defamation" of gentlemen "gasping for notoriety," had throughout the best of the argument. Still the use of alum in any degree is but at present a necessary evil. Mr. Callard, the baker, in admitting it was extensively used, said the trade would be glad if scientific men could point to some less objectionable substance, and the public will readily echo this request. We gather from what we heard, that on the whole the common opinion as to alum is a very correct one. It is injurious, and is mostly to be found in the best-looking bread. Dr. Snow has detected much less in the bread supplied to the lower classes, though he had expected that what were called cheap bakers used more than those who supplied May-fair, but such was not in reality the case.

It is a question, then, that concerns us all, and one that we trust such men as Dr. Gilbert and Dr. Odling have as yet by no means done with. They may "reform it altogether."

THE MANAGEMENT OF FARM HORSES.

It is not my intention to enter into any lengthened disquisition upon the management of farm horses; but, in accordance with my usual limits, I shall confine myself to the simplest part of the question—their every-day management whilst pursuing their regular work.

I will first notice the Stable or Shelter. Upon this point great difference of opinion exists amongst the best practical farmers. Unquestionably, if a horse is kept in a warm stable, he consumes less food; but then he is more liable to colds, and subsequent inflammations, from exposure to the variations and inclemencies of the weather in this fickle climate of ours: whereas, by being fed in a comfortable stable or shed, and having the run of a warm well-sheltered yard, he is kept in a more hardy state throughout the winter or cold weather; and in summer, the cool grass-field or the shaded yard is far more healthy after a heated day's work, and of course much to be preferred to the hot, close stable, however freely ventilated it may be from above, as the exposure to draughts of air from below ought most certainly to be avoided.

On farms having a deficiency of grass-lands, I should advocate the turning of the cart-horses, after their day's work, during the hot months of summer, into a cool paddock, there to be supplied with artificial grasses, after their usual feeding. The great aim should be to keep them in an equable, healthy state; and the best judgment of the farmer will be constantly required, to provide such food and shelter at the return of the various seasons as tend best to secure such a desirable end.

The most important part of the subject is the *Feeding* and *Food* of the Farm Horses in the different seasons of the year. Farmers perhaps err more upon this point than any other, and in a great degree from their inability, on many farms, to control ignorant or headstrong farm-servants, to whom much of the produce of the farm is frequently open, the waste of food and the irregularity of management often trying the temper of the most hearty and good-natured master. Before proceeding, I give the following extract. Spooner says: "The stomach of the horse is comparatively small, holding about three gallons; whilst the ox possesses no less than four stomachs, the first of which is considerably larger than that of the horse. This difference shows—what, indeed, the habits of these animals also demonstrate—that whilst, on the one hand, the ox is constituted so as to consume a very large quantity of food at a meal, the horse, on the other, is adapted to consume a moderate quantity, and often. If such a mass of food as is often found in the maw of the ox, were contained in the stomach of the horse, it would be impossible for this animal to perform those severe exertions which are frequently expected from him, from the loaded stomach pressing against the diaphragm—the muscle of respiration—which would materially interfere with its action. It should also be borne in mind that the progress of chymnification is accomplished by one-half of the stomach only, thus affording an additional reason why a large mass of food cannot be conveniently taken by the horse at one time." This extract contains the true principles upon which the feeding of the farm-horses ought to be regulated. It is manifest that it should consist for the most part of "concentrated food, such as grain;" and hay, straw, and roots may be supplied to the horse occasionally, but they are not his natural food.

Feeding and Food.—The common every-day experience of farmers has, I think, decided the point as to feeding. Every one adopts the system of manger-feeding, and almost universally by means of chaff and corn, followed by rack-meat consisting either of clover or meadow-hay. The horse will, of course, more readily supply himself from partially-prepared food than otherwise. Hence cut chaff is so desirable, as also split beans or bruised oats, and the like; for they have in this state the double advantage of requiring less mastication, whilst at the same time the animal derives the greater nourishment. I need not say that oats and beans have long stood prominent as the best corn-food for horses; and although many deviations have occasionally been followed by practical men, they invariably come back to the simple food of hay and corn. It is true that recently we have had various compounds brought before us; and, by an unlimited process of puffing, much is brought into consumption as food for horses. I am inclined to believe that these mixtures are good, but they are abominably expensive, being chiefly made from the meal of oats, beans, peas, barley, and Indian corn, largely mixed with the locust bean, dried and powdered, and sold at a price far above its original value. The usual allowance of corn for a farm-horse in regular work is generally in the proportion of one-and-a-half bushels of oats to two pecks of beans per week, which is ample, given with wheat, chaff, or finely cut hay and straw. My own practice is to grow for them a sufficient quantity of oats; and I give them an almost unlimited allowance of chaff, cut from oat sheaves by Cornes' machine. I am not prepared to say it is the most economical course, but I do think it one of the most healthy systems pursued, aided by a small supply of clover hay at night during the winter, and in the early spring by a few mangold roots, or Swedish turnips, or carrots, daily. In the summer the same feeding of chaff is given; and they are either turned out to be grazed in the grass fields at night, or are supplied with artificial grasses in the fold-yard. Their general management should consist of careful grooming. Great inattention is given to this point almost universally; anything will do for a cart-horse, if he is only ready for the morning's work; and galled shoulders, cracked heels, contracted feet, with divers other sores and ailments, are the result. Their stables and hovels should always have a plentiful supply of litter in the winter; and I think they should have a cool yard, paddock, or grass field for the summer. Their food should be supplied to them at long intervals, *i. e.*, a good feeding, as above, should be given in the early morning, a slight refreshment at noon—either by a nose-bag or a return to the stable, if near—and a prolonged feeding in the evening. All heating or injurious food must be avoided, or very sparingly given—as tailing wheat, barley, bran, &c. The artificial grasses should not be given to them in a fresh state. Tares ought to be mown some hours beforehand, as also should lucerne and sainfoin, both most excellent grasses for horse-fodder. If given in their fresh state, they should be passed through the cutting-box with good oat, or wheat, or barley-straw as a corrective.

I shall now only notice one other important part of the subject—it is the mode and time of working cart-horses. It is highly important that the horse should be in as close contact with his work as possible; the nearer the work, the easier will he perform it. It is most reprehensible to see, as we sometimes do, three, four, or

even five horses yoked in length to a common plough. It is infinitely preferable, where it can be adopted, to work them in pairs, or abreast; mine are frequently worked four-abreast, in various fallow work; most soils can be ploughed with two good horses abreast. The gearing should be light and simple, and the practice of driving at plough should be got rid of generally; a pair of horses, guided by either a single or double line, is quite sufficient. The question of one-horse carts *versus* waggons—of varieties in ploughs, scarifiers, harrows, and rollers—will very properly come into consideration in the economical working of cart-horses; but I cannot stay to discuss it now, and shall merely notice the time of working. It is customary in many parts of the kingdom for the horses to be out at dawn during the winter months, and at six o'clock in the summer, to return at two o'clock, for the day's work. This is good; but it is often attended with inconvenience in many seasons. In fallow-time, it is requisite that the turnip-sowing and manuring, &c., should go on simultaneously. In these months they should be rested at noon, and then worked till five or six o'clock, as required. Many prefer two yokings generally: this is a great loss of time on many farms, where the farmstead is distant. I cannot say I experience much loss or inconvenience from pursuing the practice of only one rather long yoking of nearly eight hours, in summer, with a slight rest at noon, and a mouthful or two of grass or clover, and in the winter a yoking of seven hours, without food; but I do not recommend it. Great care should be taken that the horses, when in work, should not be allowed to stand too long exposed to cold or biting winds. Most of the inflammatory diseases take their rise from such exposure. They should be steadily worked, and from their work be brought at once to the stable, and their feeding and grooming at once proceeded with.

PRACTICAL FARMER.

THE MANAGEMENT OF FARM HORSES.

TO THE EDITOR OF THE MARK-LANE EXPRESS.

SIR,—In the very excellent article which appeared in your last week's paper upon the above subject, by a "Practical Farmer," there are one or two points which I can hardly agree with, although I am aware that they are customs generally tolerated in this country, and will be approved by many. The first point to which I will allude, is "the stable or shelter." Your correspondent seems to approve of the plan of turning the horses out into a yard after being fed in the stable. Now, with the unsatisfactory state of many of our farm buildings, this may be the more preferable of two evils; for I am quite convinced that nothing could be worse than to keep horses tied up all night in a low, close-roofed stable, yet exposed to sharp draughts of air from defective weather-boarding, not divided from one another by stalls, and standing perhaps upon a whole week's accumulation of their own muck; but when we find a high, well-ventilated, brick or stone-built stable partitioned off into proper stalls for each horse (which not only tend to prevent draughts, but to prevent the animals from kicking or disturbing each other), with the floor properly formed, with a gutter behind the horses, and the manure regularly cleared out every morning, I think there can be no question of this being preferable to turning out into a yard, in the winter season, horses that have been heated to perspiration during the day. I am aware that as much liberty as possible is natural, and congenial to the disposition of every animal; but when we transgress the inclinations of nature, by subjecting the horse to the drudgery of work, a corresponding regimen becomes requisite. Nature clothes every animal according to the climate, and its natural requirements; and I am persuaded that when a horse is every night exposed to cold, that he becomes clothed with a greater quantity of hair, and consequently more liable to perspire when at work. I have also proved that by keeping horses constantly tied up in such a stable as I have described, that both accidents from each other, and diseases, are much less frequent, and particularly accidents, when new and strange horses are introduced amongst them. The other point to which I would allude, is the system of going one yoking a day, a system which I very much disapprove, considering it to be quite inconsistent with justice to the animals. The circumstances which I believe have given rise to, and still tend to support the custom, are inconveniently placed buildings, the unsuitable distance of labourers' cottages generally from their work, and the supposed saving of time, in not unyoking and yoking in the middle of the day. Now under the existing state of things, much of this reasoning may be quite plausible; but there is no reason why such things should exist. I consider it as unnatural an act as one can be guilty of to take out horses at six o'clock in the morning and work them until two o'clock without tasting food as many do; but the truth is they do not work; and the fact is, they cannot work constantly all that time, but when at plough, &c., stand at the ends at least one-third of their time. When horses are kept constantly going—as when in harness they always ought to be—there is less chance of their taking colds or being exposed to inflammations. The men will tell you that they plough an acre a day (which, however, they seldom do), and that's enough, and that they cannot do more by two yokings; but I know that however much is to be done by one yoking, more is to be done by two, with greater ease to the horses. Upon some lands from half-an-acre to three-quarters will be a good day's work, whereas upon others an acre and-a-half can be done with comfort. Men have just to consult their own feelings in order to judge of those of horses, and know whether more work is to be done in one yoking of 8 hours, without refreshment, or by working 9 or 9½ hours divided into two yokings, by 2 hours to feed and rest in the middle. Some will urge the loss of time going to and fro, yoking, and unyoking, &c. I am quite aware that there is much more time spent thus than is required, simply on account of the unwillingness of the men to fall in with the two-yoking system; with activity very little time need be wasted in harnessing and yoking horses. Your correspondent very justly remarks that two yokings are also much more convenient, the afternoon being frequently the best time to harrow for the destruction of weeds, &c. The stomach of the horse, he also truly says, is small, and unfitted for being overcharged with large quantities of food, at long intervals; and here again the propriety of the two-yoking system. I have now only to add another remark, and one of considerable importance. It is this—that "custom is second nature;" and whether, with regard to the question of "stable and shelter," or that of "one or two yokings," custom will do a great deal; for we have often observed that by altering the usual routine of treatment to which animals are accustomed they will for a time suffer from the effects of the alteration, however advantageous it may afterwards prove, so much are we all creatures of custom, and particularly the lower animals, which are destitute of reasoning faculties. There cannot be a question, nevertheless, that however much custom may reconcile to any particular plan, that can be no proof of the superiority of the plan itself. Trial and observation have induced

me to arrive at the conclusions I have now set forth. My desire is to avoid being influenced by prejudice on any subject, I shall therefore read with attention the views of any gentlemen who may choose to express themselves upon the subject, and whom you may be pleased to favour with a place in the columns of your valuable paper. Your obedient servant,

W. A.

HOW TO MAKE THE MOST OF A HORSE.

It is true that Mr. Smith, of Woolston, is gradually getting rid of his cart-horses, and as certainly inoculating his brethren with a mania for steam cultivation. Mr. Fowler again declares his share of the good work done, and only cements a union with Mr. Williams, of Baydon, to render the process yet more perfect. We are, in a word, to plough by steam as surely as we thrash or travel by it. Nevertheless the horse is going by no means out of fashion. Good grooms and able veterinarians find places and practices as readily as ever they did. There is, indeed, just now a strong proof of the increasing value of horse-flesh to be seen in the sights of London. A young American is taking ten guineas a-piece from four or five hundred gentlemen to teach them how to treat their horses properly and rationally. He numbers, moreover, in his list, not merely princes, lords, and cavalry officers. The agriculturists have even given in their adhesion to him, and Allen Ransome, and his neighbour Barthropp, are going to school again—to learn how to deal with a clever hack or a mighty Suffolk.

But if there were further proof wanting of how much agriculture still respects the horse, we may go direct to head-quarters for it. By far the most popular paper in the last number of the Society's journal is devoted to his interests. There has been no article so much quoted, and none we should think so much studied for a long time, as Mr. Miles's Essay on Horse-shoeing. It is, moreover, a very model of what such a treatise in such a place should be. It is well known that half the contributions to the Journal are never read, simply because they are too long to read. The facility with which many writers can cover an almost unlimited number of pages is ever fatal to their success. Mr. Miles then starts under favourable auspices. The most occasional of readers will not tire of him, and the most careless must learn something from what he says.

There has been no such difficulty as the horse's foot. Our own tight boots and throbbing corns sink to nothing in the comparison. Old Bowler, with a heart like a lion, takes another tug at a dead stand, and goes gloriously away with his load—only pulling three of his shoes off in the effort. The phaeton, wanted in a hurry of course, to take the master to the train or the missis to tea, is brought round by a cripple—that has been just pinched in shoeing. And when our friend does manage to get his day with the hounds, he lands the young horse in a new road to a warning cry of "You've lost a fore-shoe!" Man meets with many a contrivance to lessen his own ills. He has better fitting, softer leather, and more general attention. But what attention does he give to the fit of his horse? Is there one in a hundred who does more than curse the smith, and change one blunderer for another? We may have a fancy for a certain sort of bridle, or be particular as to the sit of saddle, and give our own orders accordingly. But the shoe is left all to the mercy of the village Vulcan; probably because of its especial importance, and the force of the truism "no foot no horse."

Let us start here. We have all in our day had to complain of these blundering blacksmiths. Mr. Miles says:

"I am often assured, when talking of shoeing, that it is quite impossible to persuade country smiths to listen for a moment to any new suggestion, or to adopt any new plan; that they are an obstinate prejudiced race, and nothing can induce them to relinquish any of their old notions. I can only say, in reply, that this does not at all accord with my experience of them as a class; on the contrary, I have found them, for the most part, to be hardworking, painstaking men, evincing great interest in their work, and anxious to do it as well as they could. I do not mean to say that there are no exceptions, because I knowthere are; but the exceptions do not disprove the rule. .... I have been sometimes surprised at the readiness with which smiths have yielded their opinion to me, as soon as they found that I really knew what I was talking about, and that I could not only give them directions, but show them exactly how to carry them out in detail, and, if I had only possessed the brawny arm which is necessary for such a purpose, that I could have forged the shoe and fitted it to the foot. They all feel that horseshoeing is open to improvement, and as a class they are anxious for information that they can depend on, but they are naturally very shy of relinquishing plans which they have been long accustomed to, for others which they do not comprehend; but any gentleman who will take the trouble to acquaint himself with the principle and details of the plan which I advocate, will very soon become a welcome visitor at the forge,and whi'e he is improving the condition of his own horses' feet, he will find that he is indoctrinating the whole district, to the great benefit of his neighbours."

Of course a man must be prepared to encounter some prejudice and leaning to conventional usage. Look, for instance, at the very first point in this delicate operation—the knowing way in which the shoe is at once wrenched off; as bad a practice as well can be. The finish, however, in Mr. Miles' eyes is a yet greater offence:—

"I shall, no doubt, astonish some persons when I assert that nearly all the evils incident to horse-shoeing are attributable to the affectation and dandyism of the smith, who is not contented to follow a necessary and useful art, simple in its mechanical parts, but calling for the exercise of some judgment in its application; but he must import into it dangerous difficulties and mischievous ornament; for instance, he assumes that a deep narrow fuller, with small nail-holes inclining inwards, and still smaller openings on the foot surface of the shoe, present a neat, trim appearance, and show that he is master of his art; knowing full well that nothing but long practice could enable any one to navigate a nail safely through a channel beset by so many dangers; but he entirely overlooks the fact that the power to do so has nothing to recommend it but the danger and risk attending the performance. Again, he imagines that a hoof carefully rasped all over imparts an air of finish to his work, of which he feels proud, forgetting altogether that he has removed a most important covering from the hoof, for which no amount of ornamental finish can compensate."

We shall not attempt to follow out the detail of Mr. Miles' system, the advantages of which are, that his horses are never lame, rarely throw their shoes, while their feet appear to last for ever. His golden rule, however, is that the shoe must be made to fit the foot, and not, as is too often the case, the foot cut out to the shape of the shoe. Further, *the shoe "must be nailed to the hoof in such a manner as will permit the foot to expand to the weight of the horse*; this lattere ondition will be best complied with by placing three nails in the outer limb of the shoe, and two in the inner limb between the toe

and the commencement of the inner quarter; a larger number than five nails can never be required in any shoe, of any size, or under any circumstances, excepting for the sole purpose of counteracting defective and clumsy fitting."

The result of this is, that on the affirmative reading of the "no foot no horse," the animal turns out to be much longer lived than people generally suppose him to be. In November last, Mr. Miles had in work in his own stable six horses—the oldest of the lot, now forty years old, he has had just twenty years. "He would pass muster for nine or ten years old," and appears only to have the slight failing of not allowing any stranger to enter his box—Mr. Rarey, of course, excepted. The next, twenty-nine years old, is "the best hack" Mr. Miles ever rode. He bought him seventeen years since, when on the point of being shot, the smith having declared his feet so far gone that he could not shoe him! The third is twenty-one years old, and has been in his present place sixteen; the fourth sixteen years old, nine of which he has been with Mr. Miles; and number five, at thirteen, has passed eight years in the same service. The sixth was recently destroyed at the age of twenty-six.

This question thus grows upon us in importance. There is, perhaps, no other horse-keeper who could say as much, simply because no other man has paid equal attention to his horses. At ten or twelve years old the animal is now frequently condemned outright; whereas with only proper care there may be quite another ten or twelve years' wear in him. We can say from our own experience that the best horse we ever had was fifteen or sixteen when we bought him, and that after three seasons' good work, he sold for more than double the price he came in at. But then he was well cared for—shod in his own box by the best man in the district, his feet regularly stopped, and his somewhat battered legs soothed and saved—especially at first—in every possible way. We must let one more extract from the article before us tell how this is still to be done:—

"If I were asked to account for my horses' legs and feet being in better order than those of my neighbours', I should attribute it to the four following circumstances: first, that they are all shod with few nails, so placed in the shoe as to permit the foot to expand every time they move; secondly, that they all live in boxes instead of stalls, and can move whenever they please; thirdly, that they have two hours' daily walking exercise when they are not at work; and fourthly, that I have not a head-stall or rack-chain in my stable: these four circumstances comprehend the whole mystery of keeping horses' legs fine, and their feet in sound working condition up to a good old age."

There is no one, we think, who will say such a paper as this is out of place in the Journal of an Agricultural Society. On the contrary, we believe it will be more read and better remembered than almost anything that has been published by the same channel. It is already issued as a shilling pamphlet; so that such of our readers who are not members may readily obtain it in this form. They must in no case be content with our mere opinion of its excellence. The essay is not distinguished as a prize paper, neither do we gather whether it was a volunteer contribution or written at the request of the editors. On any showing, it is worthy of some especial distinction. To a horse-rearing, horse-riding people like ours, a cure for lameness and lost shoes is indeed a blessing.

"LOIS-WEEDON" WITHOUT THE SPADE.

Why have not farmers in every county tested the system of wheat-growing in triple rows, with fallow intervals between? Mainly, we believe, because of the hand-labour digging it involves. It would require fourteen to twenty men, according to the nature of the land, to trench the intervals upon a hundred acres in the course of three months; and where shall we find the extra hands to do it?—not such as may always be had in winter for steam-thrashing and odd jobs, but stout, clever, and honest spademen. We say "honest" men; for the difficulty of getting a number of labourers to perform the task faithfully in every respect is a serious obstacle, even were the right sort of hands obtainable on such a large scale.

Are there no means, then, of *modifying the system so as to dispense with manual digging*, and yet realize the promised profit per acre? How far Mr. Smith has now advanced in freeing himself from dependence upon the spade and fork we do not know; but two years ago his little volume on "Lois-Weedon Husbandry" proposed to open a furrow by two turns with the plough in the middle of each interval, subsoil the furrow bottom, and after a winter's exposure, raise the crumbled subsoil and turn the pulverized furrow-slices underneath by means of a machine he has invented for the purpose. This ingenious "rotary digger," drawn by horses, was constructed, tried, and found to answer; but to what extent it has been employed in superseding manual forking we have not yet heard. In the absence of such a machine, could our *ordinary ploughs, subsoilers, and cultivators* be made to fulfil the object in view—which is, "to pulverize a certain small portion of the subsoil, year after year, and then mix it with the staple"? We thought it worth while to try, and accordingly commenced operations the year before last. Yet before we describe our management, consider how important is the experiment. For look at Mr. Smith's extraordinary results. He lays out in total expenses (including £2 an acre for rent) £5 16s. per acre on the "clay piece," and clears £5 14s. net tenant's profit—*when wheat is at forty shillings a quarter:* and on light gravelly land (clayed) gets £4 14s. clear profit from an expenditure of £6 16s. per acre. The average yield on the light land is thirty-four bushels per acre, and on the heavy land considerably more; in both cases *without manuring*. The straw is sold at forty shillings a ton; but as we cannot "dispose" of our straw at all, and should find farm-yard manure a costly article were a couple of sovereigns paid for every ton trampled down as litter or eaten by our stock, we deduct considerably from the above items, and take the prospective profit on good land (neither clay nor gravel) at say £3 10s. per acre. That is, a hundred acres permanently under wheat would gain us £350 clear annual profit, when the price is at the low figure of only 40s. per quarter; and at 50s. a quarter, the same presumed yield of thirty-four bushels is to bring us £5 10s. an acre, or £550 altogether. This was worth thinking about; for we doubted whether many agriculturists of our acquaintance could show a clear annual income of either £550 or £350 *from every hundred acres they occupied.*

Let us see how the scheme would work. Take a farm having three hundred acres arable, of very good friable loam, producing four-and-a-half or five quarters of moderately good red wheat per acre as a very fine crop, and of course less as an average; rent, forty shil-

lings; tithe, six shillings per acre; and other burdens not peculiarly heavy. Growing every description of cropping, and in rotation almost at will—say, two-fifths, or one hundred and twenty acres, are wheat every year. As it is, this proportion of wheat, together with thirty acres of oats for the horses, and also a little piece of barley, is the largest breadth of white corn we can well grow: that is, it is all that the necessity for alternating white straw with green crops, &c., will permit and enable us to prepare for it. But if wheat is to follow itself year after year for any period of time whatever, the extent of ground we can prepare by rotation is no longer a limit to the breadth we may sow. Thus, unless there be other objections, we may have half, or more than half of our three hundred acres in wheat every year; and the remainder green and other crops, according to the character of farming and live-stock breeding or feeding that may be practised. If we choose to cultivate only one hundred and twenty acres of wheat as at present, this quantity of land will be set apart to produce wheat in perpetuity; while the other one hundred and eighty acres may be all in other crops, as roots, artificial-grasses, and beans, peas, and oats, in different and rather novel rotations. But for the sake of simplifying calculation, let us suppose that *one hundred and twenty acres of the most suitable wheat land is partitioned off from the farm, to be entirely self-sustaining and bear the three-row wheat every year*; while the remaining one hundred and eighty acres is managed *as if it were a complete farm in itself*—two-fifths of it under wheat, and the rest green and other crops, as at present. We shall thus have an auxiliary 120-acre wheat-farm, as it were, not only yielding its harvest every year without manure, but producing a large amount of straw to manure and enrich what may be called the 180-acre farm. And either the same fields may be permanently kept under the three-row culture, or every year *a certain portion may be given up to the general cropping, and an equal breadth taken from the* 180 *acres*; so as to travel gradually round the whole or any part of the 300 acres with the new system. The proposal is, that on this 120 acres, independent of any green-cropping, fallowing, or sheep-feeding, we are to get an annual return of £1,140, by an outlay of £720—that is, we realize a clear profit or income of £420 a year when wheat is at only 40s. per qr., the gain rising to £660 when the price jumps up to 50s. This would be a good interest for capital, at any rate, if not exactly equal to the famous druggists' per-centage of "elevenpence-halfpenny in the shilling."

We are supposing, of course, that the cost and results will be similar to those of Lois-Weedon itself, with the necessary allowance made for the lower value of our straw. If it be found that we *can* thus raise our wheat crop year after year without manure, we shall certainly be drawing large quantities of manure (in the shape of straw) from the 120 acres, with which to fructify the 180 acres. And how extraordinarily must this great bulk of straw add to the productive power of the 180-acre farm, to which it is every year carried! Thus, by adopting this system, we are not only to gain largely in pecuniary profit from two-fifths of our land, but at the same time produce more corn, meat, vegetables, etc., from the other three-fifths: we shall raise the value of the thus more profitable farm, and create additional demand, and consequently better wages, for labour required in the treatment and manipulation of our extra crops and more numerous live stock.

There is something marvellous in increasing the total fertility of an estate *by means of a wheat crop acquired mainly from the atmosphere!* For that it is so at Lois-Weedon, let no one doubt. Mechanical tillage, without an ounce of manurial dressing, there maintains the productiveness of the wheat-fields, *with so slight a diminution of the fertile constituents of the soil itself* as not to be perceptible (we might almost think) in fifty years or a century; the land at present positively getting better, instead of gradually worse. It is a fact that Mr. Smith's twelfth year's crop is the heaviest and best he has had; and (let it never be forgotten) not only without manure, but without his bringing up or making use of an atom of fresh subsoil, only half the previously-attained depth of digging having been practised during the last three years.

"Well, but remember, Mr. Smith's results are obtained by exceedingly deep culture with the spade." Yes, on the stiff-clay piece; but on the light four-acre field, he only goes twelve or thirteen inches down with his forking; and it is possible to match this depth with horse-labour. His average yield on this gravelly land is thirty-four bushels, because, though unsuitable for wheat, it was dressed some years ago with the substance most required—that is, it received an application of clay, the charge for which is spread over a number of years. If we cannot get the expected amount of produce, owing to horse-tillage proving of inferior efficacy to that of the spade or fork, we may yet obtain, possibly, as large a surplus or *profit*, because of the lower cost of the horse-power, compared with manual operations; and "profit' is what we want. But we need not suppose that our production of corn for the community would fall short, by our thus reaping less yield per acre on the Lois-Weedon than on the common plan; because the former bears wheat *every year*, and the latter only twice in five years. Under the ordinary management, say, that each acre of the one hundred and twenty yields even the heavy crop of five quarters, that is ten quarters of wheat in five years, then a yearly produce of only two quarters from the new system will equal this amount in the same period. But we must grow more than this, in order to have a produce equivalent *in value*, not only to the wheat, but also to the crops of the other three years in the course. What crops, then, do one hundred and twenty acres usually bear every year, with a rotation admitting two-fifths to be in wheat? The quantities may be taken at forty-eight acres wheat, twelve acres oats, sixteen acres peas and beans, eight acres barley or potatoes, twelve acres clover, and twenty-four acres roots, &c. What is the worth of all this cropping; and had all been wheat, what yield per acre would have made a total produce of equal value? Now, without entering into minute figures, let us compare the corn crops at present prices, and reckon the clover, roots, &c., as worth, say £7 an acre; the value of the crops on the one hundred and twenty acres will be at the utmost about £1,200 or £10 per acre, and this is equal to the value of four quarters of wheat per acre on the whole area. So that, as far as mere worth of produce is concerned, every acre of the new system ought to yield at most some four quarters annually, in order that the national markets may not suffer. But of course, the principal consideration for the farmer is, will the expense of cultivation under the proposed system amount to less than that of the present fallowing, feeding, manuring, &c., and so leave a wider margin of profit? With Mr. Smith's expenditure, the yearly profit from this yield would be (as we have already said) about £3 per acre, when wheat is at the low figure of only 40s. The cost of our own operations by horse labour will appear in due course.

We have supposed that on a three-hundred-acre arable farm, one hundred and twenty acres are set apart for the growth of wheat year after year on the triple-row and fallow-interval method; the remainder of the farm (to make our calculation easy) being managed as if it were

a separate and complete occupation. To reap a produce equivalent to that of the crops, which would otherwise be grown, we must obtain at most four quarters per acre; and the profit, if our expenses equal those of Mr. Smith, will be £3 per acre when wheat is only 40s. a quarter. Thus much we educed in our last paper. Land, such as we speak of, sometimes yields five quarters an acre, and has been known to carry six quarters as a remarkably heavy crop; but much less than these quantities on an average. We have no doubt, therefore, that Mr. Smith could get his average produce of four-and-a-half quarters by his system of manual digging; our proposed yield of four quarters thus allowing a difference of four bushels for the inferiority of horse-tillage to that of the digging-fork. We are not at all sure that a sovereign expended in subsoiling and scarifying by horse labour would not exert as great an effect upon the crop as if spent in manual digging, &c.; as we may perhaps find the greater number of pulverizings and stirrings in the former case of equal efficacy with the less frequent but deeper and more perfect action of the hand-tool. But say that the same outlay in horse-labour tillage will not bring so large a produce; nay, let us even assume that an amount of horse-tillage costing as much as Mr. Smith's manual digging is insufficient to produce the four quarters we desire; then we may moderate and reduce the proposal to grow *manure* as well as corn; and pay back the straw, instead of consuming it, for the advantage of the hundred and eighty acres. Let the system be simply "*self-maintaining.*" Every acre of an arable occupation is entitled to its share of the manure made at the farmstead; and call this quantity, on an average, 16 loads every fourth year—equivalent to 4 loads yearly. The wheat land may not lay claim to so much as a full average share of the manure consisting of its own decomposing straw, but intermingled, as it is, with enriching roots and oilcake, corn and hay devoured by the cattle, and expensively manufactured into its present applicable condition; but certainly it may receive *manure of equal value to the straw it has furnished,* and still be "self-sustaining." Giving up, then, the idea of replenishing the other portions of the farm (without cost) by our new wheat-growing, the 120 acres are simply to take care of themselves, consuming their own straw (or straw's worth) as manure, and yielding in return for our tillage 4 quarters per acre annually. The produce of straw will be 1½ or 2 tons per acre, which we may value to the farmyard at 10s. a ton; and hence there will be 15s. or 20s. an acre to be annually spent in manure. The straw may go of course to the 180 acres which are under general culture, but must be paid for out of that portion of the business. Now, what amount of produce may be expected to arise from this sum applied in artificial manure? We might purchase 1½ or 2 cwt. per acre of guano, which (we suppose) would safely produce a gain of 5 to 7 bushels; or, rather, say a dressing of 2 cwt. of salt and 20 to 30 bushels of soot, which would probably gain much more. But remember that our crop stands upon only half the land; and the manure sown along the triple-row stripes, and missing the fallow intervals, would operate like an almost double dose, giving us say an increase of 1 or 1½ quarters beyond what tillage alone would produce.

It comes, then, to this: that if we cannot get 4 quarters an acre perpetually by tillage only, we can very likely do so by expending £1 per acre in manure; and being content with £2, instead of £3, as our clear profit when wheat is at 40s. Hence there is a good prospect for our 120 acres of Lois-Weedon wheat, few farmers clearing £800 a-year off a four-hundred-acre farm with such low prices in the corn market; and, at all events, the trial is worth making. Besides, judging from Mr. Smith's experience, and also from the indications of our own first-year's practice, we believe that the tilling, combined with the manuring, which is admissible, will raise *more* than the 4 quarters of wheat per acre for many years, if not in perpetuity; and that our profit will consequently exceed, instead of falling below that supposed.

There is another point in our favour, encouraging us to attempt Lois-Weedon husbandry on a large scale. While the crops in our district are occasionally bulky, and measure well in the barn, the weight and quality of the corn are always deficient, the usual sample being red wheat of 59 to 61 lbs. per bushel. Now, Mr. Smith finds that his roomy unconfined crop, having a stout straw, does not lodge and deteriorate when the July rains come down; the ears are colossal, and the kernels bold and beautiful, and being healthily-grown and nourished, instead of luxuriously forced and pampered, the wheat escapes pretty clearly from damaging blight and mildew; the result of all being that the highest prices are realized in the market. There will be a considerable gain, then, if we can make say 45s. per quarter of our crop, when by the common method of culture we could get only 40s.

And the system would leave blessings in its train; for suppose a field well cleaned and stirred, and worked 10 inches deep for say six years, bearing its successive grain crops without impoverishment, and then turned again to root and green-crop growing on an ordinary rotation; undoubtedly the abundant productiveness would prove the exhaustless benefit of repeated crumblings and atmospheric fertilizings, and the mangold and turnips, beans, peas, and oats would seize with a profitable avidity their special mineral nutriments that had lain unappropriated through so many years.

Perhaps we ought scarcely to mention the saving of seed, though (with 3 instead of 7 pecks per acre) this would amount to no less than 15 quarters; or the greater expedition in harvesting, the crop being what is called "all corn," carrying an extraordinary quantity of grain in rows so thinly covering the land. Neither need we hint at the continual opportunity and facility afforded for weeding, up to the very harvest day if we please. However, the more we ponder the scheme, the more adapted does it appear for meeting every exigency of the wheat plant. In winter, the furrow-slices laid up 5 or 6 inches high at every 5 feet, shelter the young plants from biting blasts, our crops being fresh and healthy when the blades on all other fields are purple and perishing. The deep-stirring and shaking of the ground in early spring stimulates the growth or bare maintenance of vigour of the wheat in spite of nipping frost; and the land, from the deep pulverization, arrests and retains moisture for the low-burrowing roots, fortifying them against the arid north-easters. The summer horse-hoeing promotes the healthy growth of the crop, pushing it on in times when other wheats are at a standstill or turning yellow. And the waving flag breathing freely because of the open-air intervals, the stems grow strong and sturdy, and ripen their grain for bread, instead of falling as crowded stalks do, to dwindle their food for the chickens.

Before detailing our method of wheat-growing on the Lois-Weedon principle, but with traction implement, instead of hand tools, we wish to impress upon our readers the considerations which led us to engage in the experiment. The proposal to have 120 acres out of 300 arable set apart for this culture has been shown to be highly *promising* in various respects; and we shall assume, for the present, that the contemplated yield of four quarters per acre can be annually reaped on our good wheat soil by means of the horse-tillage we should practise, and by the application of 15s. or 20s. worth of

artificial manure—due in exchange for the straw carried away. This, as we said, according to Mr. Smith's experience, will give us at least £2 an acre clear profit when wheat is at 40s. a quarter, and £4 profit when the price rises to 50s.

Let us now inquire whether the scheme is "practicable," taking for granted that it would answer. And, first, are the cultural processes of such a nature, and so timed, that a farmer's ordinary force of teams and labourers could accomplish them at the proper seasons, and do so without neglecting the requirements of other crops or evading the general farm work? For of course it will be useless to test with a few acresa plan that, when adopted on a larger scale, would set fast all our horses and men at inconvenient seasons, and hinder us from properly cultivating the rest of our land. Now, in "getting-in" 120 acres of wheat by our common husbandry, there are say 50 acres to be ploughed, and 70 acres to be pared or scarified and cleaned as well as ploughed; and all to be well harrowed (some rolled) and drilled. These operations occupy fourteen horses (the force kept on the farm), say twelve days in doing the 50 acres, and thirty days in doing the 70 acres; that is, the whole preparation and wheat-seeding, from first to last, takes up forty-two clear days. But potatoes and mangolds having to be harvested, turnips stored, vetches got in, stubble carted, sold produce delivered, &c., a much larger period elapses in reality between the commencement and the completion of wheat-sowing. However, if we can get-in 120 acres of Lois-Weedon wheat by forty-two days' work of fourteen horses, our wheat-sowing will take no longer than at present; and we shall not be encroaching on other indispensable labours of the farm. Well, our present (second) crop of 10 acres was got-in the first week of October. The horse-labour for clearing the stubble and scarifying the intervals ready for the seed was equivalent to ten horses for one day, and that of harrowing, rolling, drilling, and afterwards grubbing and cleaning the old stubble spaces, equalled thirty horses for a day. This amounts to forty days' work; so that fourteen horses would have accomplished all in less than three days: whence we find that 120 acres would occupy them about thirty-four days. Here we have eight days in hand—or, in other words, have sown our wheat crop in one-fifth less time than is necessary under the common system. And "early sowing" being indispensable to success, we should begin in September; so that there is no fear of want of time for putting in all the wheat on a farm in this way.

Were we to farm on the Lois-Weedon principle, having two-fifths of our land in three-row wheat, we should have the remaining three-fifths under suitable green-crops and spring corn; but, for the sake of avoiding calculations as to the apportionment of labour at different seasons among the crops in such a new order of succession or rotation, we suppose the three-fifths to be managed precisely as though it were a farm to itself under the present husbandry. These 180 acres would have two-fifths—that is, 72 acres—wheat, ploughed for, &c., as at present, requiring eighteen or twenty days' work of the fourteen horses. Our total seed-time will be altogether ten or twelve days longer than before; against which we must remember that there will be less of other work than formerly, owing to the diminished area of the other varieties of cropping.

During the latter part of October, November, and December—beginning directly the young wheat is well up, and taking advantage of periods of dry weather—the deep-working of the fallow intervals must be done. We find that one set of five horses effects this on 10 acres in the course of two days; consequently two sets, or ten horses out of our fourteen, would finish the 120 acres in twelve days. The principal tillage operation on the other portions of the farm that would be a little delayed in consequence is only the ploughing of 72 acres of stubble for pulse cropping or for fallow.

As we shall see when we come to describe our process, only half of each interval is subsided the first time; and in January and February, or directly suitable weather follows the snow and frost, the same amount of horse-labour is required to complete the deep tillage which we adopt in place of digging. This latter twelve days' work for two-thirds of our horses come just at the time when spring corn has to be sown; but bear in mind that we have 14 horses, the full allowance for 300 acres arable, while (owing to the permanent setting apart of two-fifths of the farm for Lois Weedon wheat) the breadth of spring cropping is only that proper to a 180-acre farm—that is, three-fifths of the extent which would be grown were the whole 300 acres in rotation. Instead of 90 acres of beans and peas, oats, and barley or potatoes, there will be only 54 acres; and the time saved by having 36 acres less to get in, will go far towards sparing the teams for the second subsoiling of our wheat.

Tolerably dry weather being a necessary preliminary to each of these operations, not only for the purpose of effectively breaking-up the subsoil, but also to avoid "mauling" the wheat-rows and puddling the surface with the horses' feet; it may be objected that the weather will preclude our deep tillage, except in a remarkably dry season. We have had only two winters' experience; the present one unprecedented for absence of downfall and scantiness of water in ponds, wells, and drains. But in November, 1856, our first operation was stopped by rain and then snow, after half-a-day's work; in December it was completed, though needlessly done when the ground was too wet. The second operation was performed in February, and this note was made at the time—"Several fine days before, on which the work might have been done; and if postponed, there were still several more fine days which would have given an opportunity." This last winter the first operation was well done in December after prolonged dry weather, and the second was done in February after many days in which the soil would have broken up equally well, and succeeded by plenty of bright open weather. Supposing a heavy fall of rain to follow the wheat-seeding and snow-blasts to occur, with other weather unsuitable to the drying of the ground, there would necessarily be a delay in accomplishing the tillage; but as it is during a frost that the exposure of the subsoil is most desirable, we can very well wait until any "great wets" are over. We shall have the range of at least two-and-a-half months in which to get our first twelve days' work, though on an average half the number of days in these months are more or less "rainy;" and our second twelve days' work must be caught during January and February when the weather is not at all more propitious.

Rolling the wheat in March will take up very little of the horse-power of the farm. Scarifying the fallow intervals in April or May occupies three horses for two days in doing our 10 acres, so that two sets of three each would finish 120 acres in twelve days, or twelve horses (working four implements) in six days. This will not much interfere with the fallowing and other business going on upon the 180 acres.

Horse-hoeing the intervals in May, again in June, or whenever required, will be a short matter; for one horse finishes our 10 acres within one and three-quarter days, consequently four horses would hoe 120 acres in about five days.

Hand-hoeing and weeding the wheat stripes may be reckoned upon as demanding about the same labour as a similar number of acres on the common system, the wider spaces favouring the annual weeds, though there

is less ground to be gone over. Employing a horse-hoe would of course diminish both labour, and expense.

In yoking the horses so as not to trample the wheat, in adjusting the scarifier so as to avoid casting clods upon the plants on each side, in arranging the reaping of such narrow strips of awkwardly-standing corn, there are little exercises of judgment called for; but our own experience proves that the whole management from beginning to end, is so simple that any good labourer engaged throughout one year may understand and properly execute the operations of the next.

For carrying off heaps of rubbish that may be raked or picked, and also for leading on manurial top dressings, &c., a "quarter cart" is necessary—that is, a cart with shafts fixed in front of one wheel, so that the horse "quarters," walking in the same track as the wheel, thus making a road of the "intervals" only. And for rolling the wheat rows or fallow intervals, as the case may be, it is requisite to have a roller made in two short pieces, arranged on one axle, but with a distance between them, the shafts being removable, in order that the horses (in length) may walk either in the middle or before one of the rollers, as required Only these two new implements need be constructed for our Lois-Weedon wheat-growing, the ordinary plough, subsoiler, scarifier, horse-hoe, ridge-harrow, and drill answering every other purpose.

Still further, as to the practicability of growing 120 acres of wheat, on the stripe system, upon a farm having 300 acres arable, it may be observed that the proposed mode of culture effectually provides for the eradication of couch and other creeping or perennial roots. Bunches of couch, docks, thistles, etc., may be dug out of the stubble after harvest, or from the rows of the growing crop; and the fallow intervals (embracing just half of the land) are stirred, pulverized, and the root-weeds picked off. But should the surface become thoroughly infested, in spite of all, the foulness may be extirpated after harvest, by paring and scarifying the whole breadth of the land, and harrowing lengthwise and crosswise too; obliterating the stubble-rows, it is true, and so taking away the guide-marks for the next drilling, but not preventing us (as we shall see) from hitting the right intervals, with our method of gauging the drill-row distances. But, seeing that each portion of the ground is summer or bare-fallowed every other year, no apprehension need arise of overmastery by ill weeds.

One minor difficulty we have not yet removed—headlands at both ends of a field are indispensable, for the horses and implements to turn on, in the winter, spring, and summer tillage; and no vegetable seems to covet the frequent rough usage of such a situation. Are we to try for a few stray ears of wheat, or plant potatoes with a coating of manure? leave the headlands to themselves, with the exception of cutting up weeds? or lay them down to permanent seeds?

So far, our papers on this subject have shown, we think, that growing the 120 acres of Lois-Weedon wheat by our system, on a suitable soil, is perfectly practicable; while the results, if at all in accordance with those of Mr. Smith, will be highly profitable and satisfactory.

In reply to a letter propounding our plan of horse-power tillage, Mr. Smith advised us to "say nothing about it till you have had two years' experience." This sound caution we are not following exactly; but, at any rate, we *have* had two years' experience of our method of deep-working the intervals by common implements, which was the chief practical difficulty to be overcome. And we say that our three-feet intervals of tough soil have been broken up and crumbled, and exposed to the atmosphere, to a depth of 9 or 10 inches, and that this desired end has been attained without ploughing up or otherwise damaging the wheat. Cleaning the stubble, and preparing the intervals for the seed, we have found to be simple and easy; and sowing the rows at the right distances apart has been twice done readily and correctly by a common drill. We have also kept accurate accounts of all the labour bestowed, in each process, on our 10 acres; and, having already performed the heaviest operations twice, can safely state what is the total cost of cultivation. Now, every item shall be adduced before we close this series of articles; but just at present we are insisting upon the feasibility and applicability of the system, and are anxious to exhibit its promising character: so we will only premise here that manual labour has been charged precisely what was paid for it, while half-a-crown per day is put down as the expense of a horse—certainly not too little, amounting as it does to £39 a year.

The whole cost of the crop of 1857 was £5 18s. 4d. per acre—including £2 for rent; 6s. for tithe; 9s. 10d. for rates, taxes, and 5 per cent. interest on the outlay; and £3 2s. 6d. as the expense of cultivation, in labour, seed, etc. In future years, various savings will be effected in the time spent in some of the operations; so that the total expenditure will never reach £6 per acre. What amount of produce is needed in order to repay this outlay? Three qrs. at 40s., or $2\frac{2}{3}$ qrs. at 50s.; the value of the straw—say £1—to be given back in artificial manure. And all the yield we get in excess of this quantity will be our clear profit. Four qrs. annually, we have said in a previous paper, fully equal in market-value the acreage produce of the other portions of the farm, and at 40s. would give us, it seems, a profit of £2 an acre. What was our actual yield of 1857, we do not wish to state until the second (or coming) harvest has been thrashed; but it gave us a *satisfactory profit*, and enabled us to declare that if, *after the course of management the field was previously under, so much* could be grown by means of tillage only, we are satisfied that the produce in ensuing years might be raised to more than 4 qrs. by the tillage and the sovereign's-worth of manure.

What is the history of the field? It is a strong alluvial loam, not particularly rich, but low-lying, flat, and wet; the underdrainage being effected in a shallow and half-hearted manner, by means of several very old and a few new thorn drains. The rotation has been as follows: In 1850, red round turnips (fallowed and manured for, and fed off); 1851, oats; 1852, clover (mown, and then grazed); 1853, wheat; 1854, beans (manured); 1855, wheat (a heavy crop). It was now time to fallow again, but was sown with barley instead, producing a moderately light crop on one-half of the field, though heavier on the other. This barley stubble we had to commence operations upon, so late in the autumn that no time was possible for cleaning that half of the land which was foul with couch; and the ground ploughed up stiff, and would not be reduced into reasonable tilth. Making haste to overtake the season that had slipped by (for this was at the end of October; whereas the Lois-Weedon law is, "sow in September"), we drilled the seed among large clods, the grains being finally covered with not more than an inch of "mould." On the best of the land, after the most enriching "preparation" crop in a "course," wheat badly got-in forebodes a famineus product; but following barley (after which crop the more precious cereal is considered a lost crop), nobody looked for a yield at all, though certainly the field was ploughed an inch deeper than usual. Throughout the summer the seanty crop struggled undismayed against the couch matting one side of the field, and with infesting wild buttercups and sharp thistles that sprang up everywhere after the hoers with a hydra-like pertinacity of growth. Yet, in spite of all ill circumstance

and mischance, the deep culture and pulverization of the intervals, combined with the free play of the winds and sunbeams to invigorate and swell the harvest ears, so that a small sick yielded, at thrashing, an unparalleled measure of grain in proportion to the straw. The yield, though not large, was sufficient to give a good profit per acre when sold at 50s. a quarter. Now, if a crop so put in on such ground, upon a barley stubble—the barley itself grown after wheat, without manure—paid its expenses well, is there not a better chance for the crop now coming up, sown as it was in a well-pulverized moist seed-bed that had been bare-fallowed winter and summer? At any rate, the thickly-tillered plant looks splendidly at present, and will doubtless spindle into waving luxuriance under the feeding influence of the hoe. Here we have wheat after wheat, after barley, after wheat, following beans, *manured:* a long while back to the last manuring; yet the third white-straw crop was profitable, and the rows of a fourth shine green and hopeful, with brown stripes of fertility mouldering their clods between.

Actual experience of only one year's crop, added to the bright prospect for another, may not warrant our advocacy of a revolution in wheat-growing such as our system would prove if largely carried out. We do not venture to recommend any farmer to sow all, or even half, his next year's wheat on this plan; but we do urge all occupiers of suitable soil, and whose agents or landlords are not afraid of "exhaustion," to *try a few acres*, and, our word for it, they will soon be willing to stretch the rows a little further. We are in a position to say "the culture is cheap and easy, for we have performed it two successive years; there will be no loss with the first crop, at any rate, so you need not be fearful; and the reward in many ways is so promising, that the experiment is well worth your trouble, contrivance, and risk."

In perusing the following detailed description of our wheat husbandry, let no one suppose we are presuming to stand between the Rev. Mr. Smith and the readers of his "Word in Season," or that we claim the "originality" of cultivating grain on the stripe system by means of horse-power instead of manual implements. Our method is simply a modification of that originated at Lois-Weedon, and our directions conform to those given in Mr. Smith's publications. Jethro Tull worked the intervals between his wheat-rows with the plough and "hoe-plough;" Mr Smith has progressed very far toward accomplishing his more perfect tillage by horses and traction implements; and we have simply contrived a manner of common ploughing and subsoiling between the wheat triplets, without either injuring the plants or defeating the end in view. And we trust that when the public learn how easily the thing is done, they will no longer hesitate to make trials in every suitable locality.

First, then, we would say, believe in the principle: rely upon the fact that tilling the fallow intervals does really nourish and augment the growth and produce of the wheat. For if uncertain on this point, you are sure to select a field for trial in too high a condition; the result being an early over-luxuriance and final failure of the first year's crop. Land in condition for producing a heavy crop of wheat on the ordinary plan (as, for instance, a bare fallow, a field of roots highly manured, a bean or pea stubble, or a piece of seeds richly dressed with dung or sheep-feeding) is too good to begin upon. Rather choose an oat stubble, perhaps a barley or even a wheat stubble—depending upon the known nature of your soil, and its being in or out of "heart."

Also, make up your mind to sow earlier than you would any other wheat, because there are less than half the common number of rows on an acre; which with the same quantity of seed in each row, makes a very thin seeding, and of course more than double the usual average space between plant and plant—a condition of things likely to end in mildew unless you sow early to prevent it. And besides, the great distances apart promote the stooling or tillering of the plants, the branching of the root, and shooting up of additional stems (which, indeed, forms one of the secrets of a good crop), and you will lose both in quantity and quality of corn unless time be allowed for this process to transpire before the advanced spring. So the preparation must take place very soon after harvest.

Well, the "shack" being eaten off by sheep and pigs, and the stubble (if after a straw crop) carried away, of course you will autumn-clean thoroughly; forking out couch, if the land be only slightly tainted; but, most probably, skimming, cross-cultivating, and raking off weeds and rubbish. Plough say one inch deeper than usual, in order to bring up 100 tons of fresh long-undisturbed subsoil, to supply the crop with mineral nutriment during the first year. Level and pulverize with the harrow and roll; carefully pick all root-weeds; and then comes the drilling. But mind one particular point. "Plough dry and sow wet," as Mr. Smith says: that is, do all your paring and ploughing, or ploughing followed by scuffling, or whatever order of cleaning you adopt, when the land is dry; and wait for rain to make a moist seed-bed, before you harrow fine and drill. Getting-in wheat well is always a great advantage; but is of far more consequence, one would think, when there is no store of manure in the soil to make up for defective tillage, and the preparation and treatment of the earth itself is to be the sole support of the crop. Therefore, be nice about the moisture as well as the fine tilth of the ground into which you deposit the seed; and take especial care to cut-in deeply enough with your drill coulters. A remark as to the desirability of having a fine description of seed ("red") for the sake of a bright silica-shielded straw, unless in a district famous for white wheats without mildew), and the caution of well liming, brining, or dressing with arsenic or vitriol—according to your custom—need not be addressed to men of business.

Now for the sowing. There is to be a stripe of three rows at every five feet; the "spaces" between the rows being 10 inches each (instead of Mr. Smith's "foot"), and the "interval" between the stripes, therefore, 40 inches. You want neither the slow line and dibble, nor a sort of parallel-rule wheel "marker" purposely constructed; for a good 5 or 6-feet corn drill, either with a "steerage," or with a "swing" coulter-bar and a good man for "leader," can accomplish the feat. Arrange four coulters on the drill thus: two at 60 inches apart, and, within these, two more at 40 inches apart; making the distances in this order, 10 inches, 40 inches, and 10 inches. Each outside coulter will make the middle row in a stripe of three; and the inner coulters will sow the rows next the fallow interval, the horses (in length) walking along this space left midway of the drill. When arrived at the end, the drill is to turn short, the outside coulter returning in its own track; and the seed is shut off from the pipe of that outside coulter next the unsown part of the field, so that the outside coulters act alternately as "markers" and sowing-coulters. In this way, the drill marks out its own work, without any difficulty after the first course—which the drill-leader "draws" by simple eyesight. Whatever swervings or bends may occur, the width of the interval to be cultivated is always invariable.

The next year's crop will have to be sown along the intervals between the stubble-strips; and the same mode of drilling will suffice, provided the stubble rows remain

visible, at least in some parts of the field. How then, do we manage to autumn-clean the ground?

Having harrowed up the thickest of the stubble (which must be left very short by the reapers), stir the fallow intervals with Bentall's, Coleman's, or some other scarifier set as narrow as required; and harrow them two at a time, by means of two out of a "set" of three harrows—that is, the middle one removed, so as to miss the stubble space. Rolling may be done over the whole surface; or a roller made on purpose, in two short lengths with a space between, may be employed. The stubble being pretty plainly seen, is a sufficient guide-mark for the drillmen, who cannot get far wrong when the first stroke has been taken in the right place, and if the land is in a fine state and dark with moisture. The seed may be harrowed-in with harrows covering all the ground. Should the stubble stripes be peculiarly free of couch, perhaps forking out the tufts may suffice: but we must be prepared for cleansing them when foul; and therefore have contrived how to pare or scarify them without interfering with the drilling. When the drill has begun to work, *follow it* with the broadsharer set only about 22 inches wide—not in the track of the drill, of course; but breaking up the stubble lines between the intervals just sown. We find that this operation does not displace or root-up the seed; and after it any amount of harrowing and rolling, lengthwise and crosswise, may loosen and shake out the root-weeds, without fear for the wheat in tolerably dry weather. Only this must be done before the grains have chitted; or at any rate, before the germs reach the surface.

The quantity of seed per acre depends, like the time of sowing, upon whereabouts you farm: being regulated by the quality of your soil, its altitude and aspect, its tendency as to weeds, its liability to worms and slugs, the peculiarities of your climate, the character of the particular season you may have, even the proximity of your holding to harbours of birds and vermin. What is early in one situation, may not be so in another; what is thin seeding in one neighbourhood, is thought thick in another. As an example, take our own case: November being the great wheat-sowing month with us, our present crop was got in the first week of October. In ordinary husbandry we drill 6 to 10 pecks per acre, the former quantity at the beginning of the season, when every kernel will have a chance; gradually increasing the amount as the period of sowing gets later: at the same time putting in more on poor than on rich land. Mr. Smith tried only 1 peck, but "for safety and the sake of the sample" now uses 2 pecks an acre. Our tillage being less perfect than his, and the plants lying open to greater injury from horses' treading, &c., we deemed it best to drill 3 pecks per acre. This appears but a small quantity; yet Mr. Smith's experience with a thicker seeding has shown that the stalks are too many and weak to bear up their bulky heads erect. And consider, that as the average distance between our rows (taken over the entire field), is 20 inches, we have less than half the number of rows that common 9 inch drilling gives us; and thus our 3 pecks an acre puts as much seed in every single row as about 7 pecks does in plain drilling. In fact, we drill with the same cog-wheel on the cup-barrel for both cases.

When your wheat is well up, and the triple-row emerald stripes are beautiful from end to end, comes the first really Tullian operation, namely, the ploughing along the 40 inch intervals. With a common plough, and horses "in length" (a boy leading the first horse), plough a single furrow down each interval, going say 4 inches deep. Aiming to keep the coulter 6 inches from the wheat-row on his left-hand side, the ploughman has no difficulty in taking his furrow within 4 to 7 inches of the wheat, a latitude of deviation from the true line that must be allowed him; and the upturned slice has just room to fall over, short of the wheat on the opposite side of the interval. Very few clods will be found to roll and bury the young plant.

Break up the bottom of every furrow with a proper subsoil, penetrating 5 or 6 inches, according to the strength of your team. We use Bentall's broad-sharer with the side-beams removed, a 6-inch share on the heel, and subsoil point in front, this going at least 5 inches down with 3 horses. The total depth below the surface is thus 9 or 10 inches. When the same intervals come under operation again (that is, in two years time), we may perhaps work still deeper, and it may be with a double-tined instead of single subsoiler. The horses, of course, are all harnessed in length, walking upon the furrow bottom.

Leave the field thus treated (looking lengthwise like a wheat crop, and cross-wise like a trenched-up fallow, reminding me of those corrugated pictures presenting two views at different angles), and let the frost and snow, wind, rain, and drying sunshine exert their forces upon it. And observe how large an extent of superfices is exposed; for not only can the atmosphere enter 9 inches down into the subsoil, but the furrow-slices thrown up at an angle, almost double the area of surface in the intervals.

In January and February, taking the chance of suitable weather, the same tillage is to be repeated, only on the other side of each interval. The plough turns back the pulverulent furrow-slice of the former operation, covering over the long-exposed broken subsoil in the old furrow, and going 4 inches deep below the surface level, casts up upon the top a new slice of stiff unmellowed soil for the weather to act upon as before. The horses are obliged to walk along the old furrow, treading down the crumbled subsoil; but (as it has become so friable), not inflicting much damage by compression. The newly-opened furrow must be subsoiled as before, and left in this exposed state.

So far, your tillage has provided a supply of more or less pulverized earth 9 or 10 inches in depth, on both sides of every interval, and within a few inches' reach of the wheat rootlets. And if you comprehend Jethro Tull's teaching, you will understand that soil more or less pulverized by atmospheric action must be necessarily more or less "fertilized;" hence, your growing plants will have close at hand a deep store of nutriment on which to feed during the summer. The difference, you perceive, between our method and ordinary subsoiling, lies in the circumstance that every one of the subsoiled furrows remains open and exposed, instead of being immediately buried by a succeeding furrow-slice. And it is not a mere deep stirring without inversion as performed by the tines of a subsoiler or cultivator; neither is it a complete inverting of the staple and subsoil, as in doubble-digging or trench-ploughing, that we practise. But the staple (that is, a 4-inch stratum of it) is inverted, and *removed by the plough off the subsoil that lies beneath*; and the subsoil is then torn to pieces, and submitted to the disintegration of our changeful English weather.

As far as you have proceeded at present, half the land is in undisturbed possession of the wheat rows; and the alternate halves, or intervals, are deep-worked on both sides. But as the plough opens a furrow having only 7 or 8 inches of clear bottom, and the subsoiler breaks horizontally only a few inches further toward the centre of the intervals, there will still be a ridge of unmoved ground along the middle of the interval some 10 inches in width. Therefore, in April or May, break up this, and stir the whole breadth of the interval with any suitable subsoiler or grubber. We use Bentall's imple-

ment, the central subsoiler, and two side-tires, without shares; the width altogether being 20 inches. The side wheels are set so as to travel in between the wheat rows, acting at the same time partially as rollers to press in the wheat. The depth worked with three horses on our soil is 5 or 6 inches, which moves the entire breadth of the interval, levelling the high furrow-slice left by the February operation, and mingling and incorporating a considerable portion of the ameliorated subsoil with the upper staple. And in this way, some of the previous surface-mould is replaced by portions of subsoil; and these kept upon the top, and subjected to all the scarifyings and horse-hoeings, the rain, dew, wind, and sun, of a summer and autumnal fallowing, add so much virgin soil to our field, and deepen its productive stratum.

By way of further direction, we scarcely need insist upon the watchful destruction of weeds that thieve the nourishment provided for the crop, or urge the frequent cutting of the incrusting intervals by the sharp-knived horse-hoe, to promote the absorption of the atmospheric gifts, and pulverize a rich surface-bed for the spreading wheat-roots to feed in. And of course, the wise husbandman will time this stimulating operation according to the obvious thriving or lagging growth of the plants, and will narrow the width of the implement as the season advances and the roots extend.

If possible, have the intervals in a state of powder, say by the middle of June: as you should perform another operation when the wheat is in full-ear or going out of bloom, namely, earth-up the wheat rows as you would potatoes, only with care and moderation. This may be done with a ridge or double-mouldboard plough, the horse being driven and guided by a lad walking along the next adjoining interval. Owing to excessive draught, our intervals last summer were too rough and cloddy to admit of this process being done at all; and as the seed had been imperfectly put in the ground, many odd stalks in the outer-rows were dashed down by the July storms, bent an inch or two above ground, and laid prostrate across the intervals. Gathering up these straws made tedious work for the reapers, and the grain in them was also light. Earthing-up slightly, Mr. Smith finds, will prevent this, without injury or retarding the ripening of the corn. But the stems are stronger than in a common crop, and though liable to twisting and whipping by the winds, are rarely found to lodge.

You will probably be puzzled about the best way of harvesting: the three-row strips being too narrow for mowing, and if reaped, the stubble when afterwards mown, would be only scattered and dispersed by the scythe. We paid our men extra to reap with hooks or sickles rather close to the ground, and collect the many stalks that lay athwart the intervals; and they had to leave separate "reaps" or handfulls along each stripe to be afterwards gathered into sheaves.

The subjoined items of expenditure on our 10-acre crop will give an idea of the cost of the operations now described. Manual-labour is charged at the price paid for it; and horse-labour at half-a-crown a day for each horse. The expenses, divided by 10, give *per acre* as follows:

	s.	d.
Scarifying, cleaning, drilling, &c.	16	0
Seed, 3 pecks (at 56s.)	5	3
Bird-keeping	0	4
First ploughing and subsoiling	3	8
Second ditto	3	8
Hand-hoeing wheat	1	10
Scarifying intervals	1	10
Hoe-weeding by hand	3	4
First horse-hoeing intervals	0	9
Second ditto	0	10
Reaping	13	0
Surveying reaper's work	0	3
Carrying, &c.	1	11
Thrashing and dressing	8	1
Delivering at market	1	9
Total working expenses	£3	2	6

To which, of course, are added the rent, tithe, rates, taxes, and interest on outlay. And this is the cost of *growing an acre of wheat, and at the same time fallowing that acre for next year's crop.*

It now remains for us, in concluding this series of papers, to urge the experiment upon all who are desirous of growing wheat at a profit, in spite of low prices. And should our second harvest corroborate the assurance of the first, we shall be able to enforce the adoption of the system on the largest scale.

AERATION OF LAND.

Whatever be the elements of the atmosphere by which the earth may be acted upon, it is certain that the soil, if freely exposed to such elements as present themselves in the ordinary state of the atmosphere, has its fertility greatly increased.

It signifies nothing what are the required elements, unless it be capable of demonstration that it is solely owing to some particular elements, and that those particular elements can be supplied to the soil at a cheaper rate by other means than by exposure.

To effect this exposure, it has been usual to have frequent ploughing, fallowing, drilling, &c, which conduced to this purpose, and were otherwise useful by destroying weeds; but I venture to suggest the following plan, not as a substitute for the ordinary means, but as an *accompanying measure*, which is small in first cost, and in its action attended with little expense:

Let drainage-tiles (perforated, if needful) be laid as usual; but let all the drains in a field be connected. At the lower end of the field, where the drainage is discharged, let the ends of the pipes (not perforated) be well packed in clay, and the ends of the pipes made like an inverted syphon, so that drainage-water will lodge *in the bend*. In various parts of the field—or one part, if that be found sufficient—let there be large bell-mouthed funnels to gather wind, so arranged, by means of a vane, as always to present the open mouths to the wind; and let these funnels be connected by an upright pipe with the drains.

The pressure of the wind in the mouth of a funnel will cause an equal pressure through all the drains, it not being able to escape through the ends, because of the water lodged in the bend; and air will, consequently, permeate the soil at all times when there is a breeze.

It might in some situations be possible to use water-power, or even steam-power, for an occasional service, as many well-drained farms now-a-days are furnished with steam-engines, and the aëration through the ordinary drain-pipes would be effective.

In steam-packets a long bag opened to the wind at the side, near the top, forces air into the hold amongst the cattle. Gas companies find that their gas permeates in large quantities through the soil, although their pipes are as tight as they can make them, and the ground they are laid in dense; whereas, in the plan suggested, the pressure would be in perforated pipes, and through a loose soil.

The plan would not interfere with the drainage, but would be a second use for the same pipes, and be stimulating the crops at periods when it would be otherwise impracticable to manure them. G. H. B.

THE IMPORTATIONS OF FOOD IN THE LAST TWENTY YEARS.

An official return has lately been laid before Parliament of the quantities of articles of food imported from abroad in the last twenty years, of the same kind as those produced at home, upon which Customs duties are still levied; and as the subject is necessarily interesting to our agriculturists—few of whom will see the document—we will run over the details, to see what quantities of articles we import of a like character to those produced at home.

This parliamentary return does not include live animals, salted provisions, potatoes, fish, and such-like articles, which come in duty free, but is restricted to the chargeable articles, which bring in, on the average, a net Customs revenue of about £750,000.

The imported food may be ranged under three or four groups, as grain and meal, fruits (raw and dried), dairy and farm products, beverages or substances used in their preparation, and a few minor items.

First, then, we have grain, the imports of which have necessarily fluctuated largely in the series of years under consideration, consequent upon the vicissitudes of seasons and the variable demand for food supplies, according to the nature of our own and the European harvests. Thus, while in 1836 we imported but 168,647 quarters of foreign wheat, in 1853 we received nearly 5,000,000 quarters; and the average importation of wheat in the last ten years has been 3,500,000 quarters. To this has to be added the wheat flour, and other grain and meal.

During the last ten years our annual imports of wheat and flour have amounted, on the average, to 5,000,000 quarters; a very considerable part of which has been derived from Russia and countries situated in the Baltic, Turkey and Egypt, the United States, and Canada.

Our supplies of foreign wheat-meal or flour, which from 1839 to 1845 scarcely averaged 1,000,000 cwt. per annum, have since averaged about 4,000,000 cwt.; although last year there was a decline of nearly 2,000,000 cwt. as compared with the previous year's imports.

Of Indian corn or maize, the imports may now be taken at an average of 1,250,000 quarters per annum unground; and a yearly decreasing quantity of the meal—in 1836, 4,000,000 cwt. Compared with the enormous imports to supply the Irish famine-wants in 1847 and 1848, the present imports look very insignificant. For bread or human food in any shape Indian cornmeal will, however, never make any headway in this country; the colour and flavour being repugnant to the popular taste, which demands wheaten bread as its mainstay, whatever be the price. The consumption of maize here is, therefore, chiefly as food for live stock and the manufacture of starch.

The imports of foreign barley fluctuate considerably, ranging from only 100,000 qrs. in one year up to nearly one and three-quarter millions last year. The imports of barley meal are trivial, amounting to a few tons; but it seems strange why the 50 or 60 tons of pearl barley could not be made at home. About 1,000 or 2,000 quarters of bere or bigg come in annually.

Of oats, our average imports of late years have been about 1,000,000 quarters, although last year it reached 1,710,300 quarters. Of oatmeal, we seem to draw larger quantities from abroad; the imports averaging 1,000,000 qrs. Our foreign supplies of rye are very uncertain: in some years we have imported 100,000 or 200,000 quarters; in others the supplies are small, amounting to but 1,000 or 2,000 quarters; in 1856, we imported 28,000 quarters. The figures for last year are not yet made up. About 7,700 cwt. of rye meal were also imported in 1856.

Of the pulses our foreign imports do not vary much, at least of late years; about 100,000 quarters of peas and 350,000 quarters of beans are near the average.

Grain pays the duty of 1s. a quarter, and meal 4½d. per cwt.

There are a few miscellaneous preparations of grains and seeds which may be mentioned. Firstly, an increasing supply of semolina—a preparation from the wheat of the southern parts of Europe. The best is the fine hard parts of the grain, rounded by attrition in the mill-stones, and made chiefly in Italy. We imported 1,300 cwt. in 1856. In France, however, this name is given to the large hard grains of wheat retained in the bolting machine after the fine parts have been passed through its meshes, and with this, when ground, the fine white Parisian bread is made. Of vermicelli and maccaroni, other Italian preparations of wheat, we import about 5,000 cwts., subject to a duty of 1s. the cwt. An article termed "manna croup," comes in in small quantities. In 1853, 1,467 cwts. were imported; and in 1856, 453 cwts. were received. Properly this name is applied to the seed of the wild grass *Glyceria fluitans*, a very nutritious grain, collected in streams in northern latitudes, and much used in soups, or for porridge in Germany, Poland, and Russia; but that which we import is exclusively a preparation from wheat, passing under the name and competing with semolina. What the "mixed mustard" (which comes in to the extent of 150 cwt.) is, we scarcely know. It is not mustard-flour, for there is a separate heading for that in the return, and our home growth of mustard seems fully adequate for the supply: it cannot be French vinegar-mustard to this amount, and therefore it is probably adulterated mustard-flour, rated at 5s. the cwt. against 1s. 6d. the cwt. duty on pure mustard-flour.

Besides the foregoing enumerated articles, we received 35,300 cwts. of biscuit and bread in 1856.

The imports of foreign butter continue steadily to increase, but this supply would go a very small way towards buttering the bread eaten by our population, to say nothing of the other culinary uses of butter. Our imports of butter last year amounted to 442,837 cwts., and of cheese 394,749 cwts.; but we managed to export of these two dairy products 111,008 cwts. of butter, and 28,000 cwt. of cheese; so that with our own dairy produce we could do pretty well even independent of Dutch butter or American and Dutch cheese. Eggs, however, still form a large and increasing item of import, and for these there is an enormous home consumption. An increased supply of ten or twelve millions a-year of French eggs comes in usefully for the necessities of the cook and the manufacturer, there being a large demand in many trades for eggs, exclusive of our food wants. Last year the imports reached 127 millions!

Of beverages, and substances used in making them, we imported in 1856, 11,500 gallons of beer, and at duty of £1 the barrel of 36 gallons.

The quantity of foreign hops received varies. In 1854 we imported 119,040 cwt.; but since the duty has been raised to £2 5s. the cwt. the quantity has declined,

the imports last year being 18,712 cwts. The average annual imports of hops the last three years have been 19,720 cwt.

A fair amount of roasted chicory still comes in, our receipts from the continent in 1856 having been 24,000lbs. —very greatly below, however, the large imports in 1853 of 134,644lbs. The principle of admixture with coffee seems to be largely checked by the Excise regulations, which compel the sale of chicory in separate packets or labelled as a mixture. Whether the home growth of the root has been interfered with, we do not know.

There is an enormous import of carrawayseeds, which reached 12,485 cwt. in 1856, paying a duty of 5s. the cwt. One would scarcely suppose that, besides the home growth, there should be so large a demand for this aromatic seed for confectionary purposes, pharmacy, and making an essential oil.

There is a large amount of fruit of various kinds received from the continent and elsewhere, owing to our variable climate being less certain and favourable for the early production and ripening of many kinds. Thus pears, apples, and cherries come in in considerable quantities. For instance, in 1856, we received 531,291 bush. of apples, 22,532 bush. of pears, 17,651 bush. of cherries, small quantities of medlars, quinces, &c , besides 97,000 bush. of unenumerated fruits. In addition to these, there were 2,364 casks of dried apples, 32,642 cwt. of dried plums, small quantities of dried cherries, pears, &c., and 56,534 bush. of walnuts; 127,000 bush. of onions may perhaps be included in this class. These, with some vinegar, pickles, and sauces, make up the category of duty-paid articles competing with home-grown produce.

There are, as we have before remarked, some few other important food-products entering duty-free, such as animals, salted provisions, and potatoes. Thus last year we received 606,606 cwt. of salted meat, bacon, and hams, 182,860 cwt. of lard, 955,057 cwt. of potatoes, and 281,000 living animals for food.

But how trivial would these be, towards our home demand! And against these foreign imports we have also to set off the large exports of home produce of agricultural origin. For instance, last year we shipped 435,000 barrels of beer and ale, 110,008 cwt. butter, 28,000 cwt. cheese, 4,821,277 gallons of British spirits, and pickles and sauces of the value of £355,496— making up for these few enumerated articles a total declared value of nearly £3,500,000, besides many others of smaller gross amounts. Judging from the average of years, our food exports may be taken at fully £5,000,000 in value.

REVIEW.

THE EVIL RESULTS OF OVER-FEEDING CATTLE.—A NEW INQUIRY.

By F. J. Gant.—Churchill.

It is now just about twelve months since that we had to call attention to a rather remarkable pamphlet on the meat trade of the metropolis. The author of this, Mr. Gamgee, showed that, despite our amended regulations and improvements, the traffic in diseased flesh was of itself a regular business. He found sick animals openly offered for sale even in the new market at Islington; while he traced their carcases to Newgate, Leadenhall, and other public resorts. Whatever people might think of it, there was really no mistake about the fact. The lower classes, most likely, were the chief sufferers. Indeed, Mr. Gamgee's argument went to this. Meat unfit for human food was bought and sold clearly on the understanding that it was to be had cheap. Perhaps we were all very sorry for "the poor people," and there was an end of the matter. We certainly never heard that anything more came of it.

The story, however, is hardly told out yet. It may be brought a little closer home to us all. Another member of Mr. Gamgee's profession—another medical man, that is—has also been pursuing his scientific researches, and with this result — that what we consider the *best* meat, he considers is the least fit for consumption! Mr. Frederick James Gant, surgeon and pathological anatomist to the Royal Free Hospital, went, like all the rest of London, to the last Christmas Fat Cattle Show, at the Baker-street Bazaar. His "limited opportunity for examining them" still enabled him to detect—as he says—a number of diseased beasts, sheep, and pigs. What mostly struck Mr. Gant, at the outset, was what has no doubt taken the attention of almost everybody else. It was, in his own Italics, "*the size of the animals compared with their respective ages.*" Precisely so. One of the chief objects of breeders, and particularly of such societies as the Smithfield Club, is early maturity. That is to say, we get a beast, bigger and better, at half the expense in time and capital, you could have done with the old unimproved races. There is hardly such a thing, now, even as old mutton. But Mr. Gant looks at this in a very different light, and is by no means willing to join in the self-gratulation with which we have been greeting each other :—

"When I contrasted the enormous bulk of each animal with the short period in which so much fat or flesh had been produced, I naturally indulged in a physiological reflection on the high-pressure work against time which certain vital internal organs, as the stomach, liver, heart, and lungs, must have undergone at a very early age. Now with the best method of rearing cattle, or that which is most conducive to their health, the medical profession are only indirectly concerned; but of the *dietetic value* of animals so reared for food, the profession are, or should be, the immediate overseers and arbitrators."

In accordance with this conclusion, Mr. Gant follows up many of these animals to their last homes, and, thanks to the courtesy of Messrs. Jeffery, King, Gorton, Sack, Sinkler, and others, sees most of them slaughtered. Alas! the prime joints and noble carcases these liberal buyers pride themselves so much on, would seem to be little better than a delusion and a snare. Those fine ribbons, Christmas favours, and first-prize decrees, proclaim to science but little more than that such meat is not fit to be eaten. The more distinguished they appear to have been in the Show-yard, proportionately the worse do the animals turn out in the slaughter-house.

In a series of really beautifully got-up plates, the first we come to is a coloured illustration of "a diseased heart of a sheep by conversion into fat." This is found to be a Gold Medal sheep, one from a pen of fat wethers, the best of all the Short-woolled—his Grace the Duke of Richmond exhibitor and breeder. Then we have depicted the diseased lungs of a sheep, one of the best of all the Long-wools—Lord Berners exhibitor and breeder. On the same page is the portrait of a diseased

or unhealthy mutton-chop, from the loin of the gold-medal Southdown. Further on we turn to "the diseased heart of a Devon heifer, by conversion into fat"—his Royal Highness the Prince Consort exhibitor and breeder. There is only one grand moral example wanting, and that forms the illustration of a whole page—"the diseased heart by conversion into fat," of the gold-medal Short-horn—Mr. E. Wortley exhibitor and breeder. There is no mistake, no shy fighting here. In the first place, you are shown the heart of an animal in the healthy state it should be, and then that of one diseased by over-feeding. Let Mr. Gant's text speak further to this. He is now going the round of the yard:—

"My limited opportunity for examining them enabled me to detect no external sign of disease, except in two Devon cows, Class IV., Nos. 32 and 33, prize £5, each of which was suffering from *prolapsus vaginæ*. One of them looked very ill, and laid her head and neck flat on the ground, like a greyhound. I pointed out these animals to a man who was drawing water, and I asked him if their condition was one of common occurrence. He said, 'I knows nothing of them beasties in p'ticler, but it's the case with many on 'em, I knows that.' I passed on to the pigs. A pen of three pigs, belonging to His Royal Highness the Prince Consort, happened to be placed in a favourable light for observation, and I particularly noticed their condition. They lay helplessly on their sides, with their noses propped up against each other's backs, as if endeavouring to breathe more easily; but their respiration was loud, suffocating, and at long intervals. Then you heard a short, catching snore, which shook the whole body of the animal, and passed with the motion of a wave over its fat surface, which, moreover, felt cold. I thought how much the heart, under such circumstances, must be labouring to propel the blood through the lungs, and throughout the body. The gold medal pigs of Mr. Morland were in a similar condition, if anything, worse; for they snored and *gasped* for breath, their mouths being opened, as well as their nostrils dilated, at each inspiration; yet these animals, only twelve months and ten days old, were marked '*improved* Chilton breed.' They, with their fellows just mentioned, of eleven months and twenty-three days, had early come to grief. Three pigs of the black breed were in a similar state at seven months, three weeks, and five days; yet such animals 'the judges highly commend.'"

This is very graphic, and almost amusing in its tone, were not the injury said to be of so serious a character. We shall not follow our author into the dissecting-room, of his labours, in which he gives further and yet more useful illustration. We must be content, the rather, with the chief result and its consequences:—

"Under the present system of rearing and feeding, one disease is of most frequent occurrence, namely, conversion of the heart into fat. I am supported in this opinion by the invaluable testimony of Professor Quekett, of the Royal College of Surgeons, who re examined the hearts in question, and confirmed my observations."

The consequences are—

"That in over-fed, corpulent animals of forced growth, the muscular substance of the most vital organ, the *heart*, is pallid, soft, and greasy; and that its fibres then contain fat instead of the fibrillæ, in which reside both the contractile power of muscle, and its nutritive value for human food. We therefore say that such meat no longer retains its healthy structuae and nutritive quality, although when degenerated into fat, it may still present the semblance of ordinary muscle, and thereby deceive both buyer and seller. We should therefore expect in vain to replenish our own muscles by the use of such food, nor should animals thus overfed be regarded as prize specimens of rearing and feeding. The heart, being converted into fat, no longer retains its contractile power, but beats feebly and irregularly. The blood, therefore, now moves onward in a slow and feeble current. Hence the panting breathlessness due to stagnation of blood in the lungs, which the heart labours (in vain) to remove, while the skin and extremities are cold. Hence the stupid, heavy-headed expression of a congested brain, and the *blood-stained* appearance of meat after death. The slightest exertion to an animal, under such circumstances, might suddenly prove fatal. Were a man, in this condition, to present himself at an insurance office, it would refuse to insure his life at any premium. *Yet, under similar circumstances, a sheep is awarded gold and silver medals, and its feeder a prize of £20!!*"

Mr. Gant's remedy—for we prefer that he should speak for himself—is:—

"Instead of pursuing the present system of rearing cattle, much as it may test the qualities of food, and other matters of minor importance, let breeders, feeders, exhibitors, and prize judges alike visit the slaughter-houses; let them do this with a due knowledge of diseased appearances, and let them thus discover that system of rearing which is most compatible with the health of cattle, and which produces the largest amount of the most nutritious food for man. Under the present system the public have no guarantee, and are not insured the best, if indeed the cheapest food. The bulky withers of a fat bullock are no criterion of health, and its flat tubular back may conceal the revolting ravages of disease."

If we recollect aright, in the early days of the Smithfield Club this was done. The judges inspected the carcases of the animals after they were killed, and revised or confirmed their decisions accordingly. As the Society increased in influence and numbers, no doubt the practice was found inconvenient, if not altogether impracticable. Still, the fact that this has been done gives weight to the suggestion, and shows that Mr. Gant asks nothing but what the Club itself has already some precedent for. His pamphlet, originally the subject of a communication to the *Observer* newspaper, is called "Evil Results of over-feeding Cattle—A New Inquiry," and is dedicated to the agriculturists of Great Britain and Ireland. However sound or unsound his deductions may be, we must do Mr. Gant the justice to say that he has spared no trouble nor expense in perfecting his work. The plates alone must have been very costly, and for the original of one—the diseased heart of the Shorthorn—he paid no less than half-a-guinea!

There is one reflection forces itself upon us here. If animals intended for the butcher are really in this diseased condition, what evils must follow from breeding-stock being almost equally over-fed? And yet our experience of only last summer recals pigs and sheep in this panting, helpless state; while one of the prize fat cows at this very Christmas Show was sent home again in calf! To us it is very satisfactory to feel, that of this branch of the evil we have long continued to complain.

WOOL AND WOOLLENS.—IMPORT AND EXPORT.

Incidental mention was made by Mr. Ashworth, in a paper on cotton read at a recent meeting of the Society of Arts, of the Increased Production of British Wool, and he inferred that the increased consumption and enhanced prices were mainly due to the introduction of an admixture of cotton with wool in various fabrics; "the attractions of the article manufactured, together with its comparative cheapness," according to his dictum, having called for more wool, and, with this increased demand, led to a greatly-improved price.

Now, we are not prepared to admit to the full the reason so plausibly assigned by the cotton advocate, nor to place very great reliance on his statistics regarding wool. He states the British wool grown in 1857 at 143,042,782 lbs. at 19d. a lb., which gives a value of £11,322,219. That grown in 1835 he fixes at 108,000,000 lbs. at 13½d. a pound, making an aggregate of £6,075,000. This change in the manufacture from pure woollens to mixed wool and cotton fabrics, he tells us, has been attended with an unexpected gain to the British wool-growers, by an increase of trade and higher price amounting to 5¼ millions sterling.

The same increase of prosperity, and to a large extent (Mr. Ashworth adds), has been shared by the sheep-farmers of Ireland; but the accounts are not clear, in consequence of large quantities of Irish wool having been sold for shipment to France, Belgium, and Germany."

Now, however well read he may be in the history and statistics of the cotton trade and cotton manufactures of the country, we fear Mr. Ashworth's views and figures respecting wool and woollens are less to be relied on; and we must, therefore, join issue with him on several points.

France we know to be, like ourselves, a large importer of foreign wool; but we are not aware that she seeks specially that of Irish origin, and we doubt whether the Irish wools do not, for the most part, go to Liverpool, and, through the public wool sales there, enter largely into the British manufactures. From 3,000 to 4,000 bales of Irish wool, we know, reach Liverpool annually, the average import of the last six years being 3 300 bales.

French buyers no doubt appear at our London sales, as do purchasers from other parts of the Continent. We have not the latest figures of the imports of wool into France, but in 1853 France imported 48,400 000lbs. of wool. She has of late years been paying increased attention to sheep-culture in Algeria, where there are now about eight millions sheep, and about sixteen million pounds of wool are produced there.

We next join issue upon the quantity of sheep in the kingdom, and the British wool produced; and here we certainly enter upon very debatable ground. Unfortunately we have no return of the number of sheep kept in Great Britain. Mr. Braithwaite Poole, in 1853, estimated the total annual growth or produce of wool in Great Britain and Ireland at 32,000,000 fleeces, averaging 4 lbs. each; and taking the wool to be worth 1s. a pound, this would give a total value of nearly £6,500,000. In the official British catalogue of the Paris Exhibition (1855), the estimated annual produce of wool in the United Kingdom is stated to be about 130,000,000 lbs.

It is easy to assume figures; but estimates necessarily differ; and we would refer to Mr. McQueen's Statistics of the British Empire (p. 21)—no mean authority—who estimated the production of British wool in 1835 at 246,700,000 lbs., valued at £13,979,166, and the foreign wool then imported at 46,500,000 lbs., valued at £3,750,000. If the number of sheep were then 48,000,000 in the kingdom, although this may have been too high an estimate, they must in twenty years have somewhat increased. We know, by the agricultural returns, there are in Ireland and Scotland at the present time about 9,000,000 sheep, and in England and Wales there cannot be less than 40,000,000; and at 5 lbs. per head all round, the wool produce of the United Kingdom would be 245,000,000 lbs.—no increase, after all, upon Mr. McQueen's estimate.

But, then, these assumptions depend upon very uncertain data, owing to the absence of precise returns of the sheep in England, and the different average weight of the fleece, which would not perhaps equal 5 lbs. per sheep all round, now that short-woolled sheep are more general than they were in former years, and making allowance for lambs.

We now receive much larger supplies of foreign and colonial wool than formerly, our imports having nearly trebled in twenty years, reaching in 1857 to 129½ million pounds. And our shipments of woollen yarn and fabrics to foreign states and our colonies are also on a largely increased scale, owing to the increase of wealth and population. While in 1835 our woollen manufactures and yarn exported were only valued at £7,000,000, in 1857 they reached £13,647,186.

But this was by no means owing to the extraordinary ability or skill of the cotton manufacturers; for only £2,000,000 in value of the exports came under the denomination of "mixed fabrics," and the home consumption of these mixed cottons and woollen goods was certainly not so large as that.

We cannot pass over, in our consideration of British wool, the increase in our Colonial production. Australia and New Zealand, the Cape Colony, British India, and Canada have largely increased their number of sheep, and their yield of wool. In Australia, in the two principal colonies, we find, in 1855, Victoria had 5,322,000 sheep, and clipped 22,353,000 lbs. wool; New South Wales, 8,144,000 sheep, and clipped 17,671,000 lbs. wool.

The apparent anomaly in these figures is attributed to two causes: the lighter fleece of the old colony, and the fact that Port Phillip is of more convenient access to the south-western district of New South Wales than Sydney, and therefore receives the pastoral produce of that locality.

But the considerable trade of those parts of New South Wales and of the adjacent portion of Victoria is now vigorously contested by a third party, the colonists of South Australia, who have already navigated the river Murray as far as Albury, and conveyed the wool by steamers and barges to the shipping port of their own colony. The wool produced on extended pasture runs in the northern runs of Australia, now that the Moreton Bay district is to be formed into a separate colony, will no longer swell the returns of Sydney.

The export of wool from Port Phillip has slowly increased in spite of the attractions of the gold diggings. Only one year was it beaten back (1851) as will be seen from the following table:

YEARLY EXPORT OF WOOL FROM VICTORIA BEFORE AND AFTER THE GOLD DISCOVERY.

Years.	Wool, in lbs.	Years.	Wool, in lbs.
1846 ..	6,406,950 ..	1851 ..	16,345,000
1847 ..	10,210,030 ..	1852 ..	20,247,000
1848 ..	10,554,663 ..	1853 ..	20,843,000
1849 ..	14,567,005 ..	1854 ..	22,998,000
1850 ..	18,091,000 ..	1855 ..	22,353,000

The imports from the Australian colonies last year fell back to about the produce of 1855, being 49,000,000lbs., having in 1856 exceeded 52,000,000lbs.

Various inducing causes, other than the trivial reason assigned by Mr. Ashworth, must be looked to as having stimulated the production of British wool at home and abroad. The tide of emigration; new and extended pasture land in Australia, New Zealand, and SouthernAfrica; the progress of settlement in Canada; the extension of trade with Central Asia (our imports from India having risen to upwards of 19 millions); the diffusion of wealth owing to the gold discoveries and increased commerce, and the greater attention paid to sheep culture, owing to the demand for food—all these and other reasons might be much more truly assigned for the existing prosperity and enhanced demand.

SPRING PROSPECTS.

The past season has been a trying and an eventful one to most farmers. We were comforting ourselves with ideas of permanent prosperity, and cosingly imagining ourselves snugly reposing in the warm nest which the past two or three years of "good times" had enabled us to build, when suddenly a storm arose—a tornado in the commercial world, and crash after crash gave ominous sounds and unmistakable warnings. Soon the flourishing tree upon which our hopes depended was shaken to its very roots, its leaves shed all driven and gone, and its branches were broken and scattered by the storm. Such was the sudden and unexpected turn of affairs in the agricultural world consequent upon the shock to commercial credit. It was incredible; at first, few would be induced to believe it. Failure succeeded failure in rapid succession, and at length the general body of farmers were convinced that, for the present at least, their prosperity had waned. A reaction was the result, and needless alarm at once took the place of incredulity: hence the farmers began to pour supplies upon the markets, and an unusual and unwarranted depression in prices has been the consequence. Now my object in this short paper is to try and stem this downward course, and bid my brother farmers take courage. The worst is over; be patient: signs of renewed activity in the commercial and manufacturing departments of our country's industry appear, and serve to show that speedily you will feel the benefit of an increased demand for your indispensable products. The trial has been a severe one; but I trust it has passed or is fast passing away, without leaving distressing evidence of its effects; and, in reliance upon the energy, the enterprise, and the vast resources of our astonishing country, I would urge a renewal of every effort, as farmers, and the adoption and practice of those safe and salutary improvements which modern agriculture has developed and confirmed. Our mainstay and safety is in the improved practice of agriculture, so that, "come what may," we can face the world's markets, and no longer entertain such dread of foreign competition. But to my text: "Spring Prospects"—the crops.

The Wheat Crop.—There probably never was a winter better adapted to uphold the security of the wheat plant than the past. Throughout the whole season scarcely any damage has been sustained, and the fullest and most healthy plant ever known has been the result upon the average of the country; indeed, but few districts have a thin plant. In fact, the plant is too full—too much crowded, if anything, to be more than usually prosperous; a fault, if it be one, not to be greatly deplored: we have often to complain of thinness of plant, and but seldom the contrary. The wheat crop, then, has an abundant plant; and we have every evidence of its favourable progression. The season for rolling or compression has been most favourable, and a good firm seed-bed has been obtained, which is universally known to be so conducive to the safe growth and prosperity of the seed-crop. There has also been a sufficiency of cold and frosty weather to keep the plant in check, so that scarcely any crops have become winter-proud. Should the season continue favourable, we anticipate an early harvest and a good crop.

The Spring Crops.—*Beans, Peas, Barley, and Oats.*—These have all been put in under the most favourable circumstances. The soil is in the finest state imaginable to receive the seed; they have been early sown, and every good grain may and must grow; indeed, in the majority of cases, the plant has made its appearance, and looks remarkably well. The bean and peas seed lay a somewhat prolonged time in the ground, but came up safe and healthy-looking. We cannot, under such favourable auspices, avoid coming to the conclusion that the prospects of our spring cropping are also remarkably good. The land being in fine condition, we anticipate a rapid and full growth, the oats most probably requiring, on the best land, topping to retard their progress.

Potatoes.—The season for making preparation for this crop has been all that could be desired. The soil is in a finely pulverized state, and the crop is for the most part planted under every condition advantageous to its growth. A large breadth, too, has been got in, and being thus early, we augur a greater freedom from disease, and a corresponding yield of marketable tubers, the earlier settings generally producing the greater quantity of large potatoes. We should greatly rejoice to find that this unusually mild winter has tended to put an end to the mysterious scourge we call "potato disease;" it would indeed be a blessing most worthy of a nation's gratitude.

The Root Crops.—We never knew farm work in such a forward state: great progress has been made in fallowing and preparing the land for the root crops; a fine tilth has in innumerable cases been already obtained: the fear is that continuous rains may set in, and prevent the completion of the fallow: so far everything has been favourable. Much land is in preparation for the mangold wurzel crop. This crop continues to obtain greater favour with the agricultural public, and its culture is widely extending. We are heartily glad it is so. It is an invaluable crop, and ought to be grown by every farmer who has stock to keep. The culture, management, storing, and mode of consuming it *is now so* patent, that every one may adopt it as a farm crop with advantage.

The Grazing Department.—The grass-lands as a whole do not correspond with the favourable state of the arable-lands. The absence of snow, "the poor man's manure," during the winter, is and will be felt. About a month since they looked sadly, being brown and very bare of grass. In the past week or two they have recovered their greenness, but are slowly progressing, and will not be ready for the early stocking we were looking forward to. This will be severely felt, as the winter keeping (mangolds excepted) has for the most part long been finished, and much difficulty is experienced by flock-masters in providing for their flocks: this has led to many forced sales, causing, a few weeks since, a great depression in store stock. This, however, has been recovered, and this kind of stock is now selling at a remunerative price to the breeder, but at a rate not likely to leave a fair margin of profit to the grazier. Fears are also entertained relative to the healthy state of the flocks, owing to the very inferior quality of the winter food they have been compelled to subsist upon. This, I trust, is in a great measure unfounded, as the general resort to corn, cake, and other artificial condiments would keep them in condition, and prevent the injurious consequences arising from unwholesome food. The number of sheep to be brought forward will undoubtedly be considerable, as, owing to the fineness of the winter, the casualties have not been very great. The only danger is from the unwholesome character of the turnip

and coleseed crops upon which they were fed, and consequently the absence of condition requisite to being put to good grass: nearly all of these crops suffered from mildew. From this cause also we anticipate a falling off in the condition of the cattle brought forward. It is true, abundance of cake may, in a great measure, compensate for the absence of quality in the turnip; but this abundance will not in all cases be given. Many yards of cattle will come out in their usual splendid state, the pride of their exhibitors, fit either for the butcher or for further grazing; but this class of animals will form the exception, not the rule, this year. Nothing, upon the general average, will compensate for a defective turnip crop: it must be felt in the summer's grazing. I therefore anticipate a short supply of well-fed animals, both in cattle and sheep, for the grazing department, and consequently a scanty supply of marketable meat for the first summer months; this generally leads to many animals being sent to market before they are properly fatted, which tends strongly to depreciate prices. One word relative to pork. The supply of good store pigs has greatly increased; and as these are fatted as porkers, the tendency will be to produce a greater reduction in the price of meat; even at present, pork does not retain its relative value in the markets.—I am well aware these remarks are not of much worth; but I am desirous to provoke inquiry, therefore they are meant to be more suggestive than dogmatic.

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE USE OF GUANO FOR ROOT CROPS.

The ordinary monthly meeting for discussion took place on Monday evening, April 5, at the Club-house, Blackfriars.

Mr. Owen, of Clapton, as Chairman for the Year, presided. In consequence of the meeting falling on Easter Monday, the attendance was not large, but it included Messrs. R. Baker, H. Trethewy, John Thomas, T. W. Granger, C. T. James, L. A. Coussmaker, W. Gray, T. F. Wilson, J. Wood, J. C. Nesbit, T. Hatfield, T. B. Chapman, James Thomas, E. Purser, J. Howard, J. G. King, J. Cressingham, J. Wood (Croydon), T. Congreve, S. Skelton, H. Owen, G. S. Harrison, R. Marsh, W. W. Good, Owen, jun., &c, &c.

The subject for discussion assigned for introduction to Mr. W. Sainsbury, of Manor House, West Lavington, Wiltshire, was thus stated on the card: "The Advantage of Guano for Root Crops, and the Best System of Applying it without Injury to the Germination of Seed."

The CHAIRMAN, in opening the proceedings, observed, that the best method of growing roots must always be an interesting subject to the farmer; and, knowing how great Mr. Sainsbury's experience was in reference to it, he was quite sure that gentleman would treat the topic in an interesting manner. He was sorry that at the present moment the article of guano bore such a very high price in the market; but he had no doubt that Mr. Sainsbury would show that even with that price the use of guano was attended with great advantage; while, on the other hand, as it was a most valuable manure, he trusted the day would soon arrive when it would be obtainable at a far lower rate.

MR SAINSBURY said: Mr. Chairman and Gentlemen, the subject for discussion this evening is one, I think, of the greatest importance to the farmers of this country. The value of guano has been tested by many practical men, by a comparison of it with a variety of artificial manures. I have myself taken much care to give the thing a fair trial. I well know how cautious I ought to be, in stating the result of my experience, and I have no doubt there are many practical men present who are much more capable than I am of explaining in detail experiments in relation to this subject. I do not presume to teach, or dictate in any way; I only wish to give an exact statement of what has taken place on the farm in my occupation, with different manures in competition with guano; and I regret that the subject has not fallen, for its treatment, into the hands of some member of this club who is more competent to expatiate on it than myself. I consider that by increasing the weight of roots per acre, we secure the means of keeping more stock, thereby laying a foundation for good farming. (Hear, hear) It is my intention to state, on this occasion, the result of three years' experience respecting the different kinds of artificial manures which I have used in competition with Peruvian guano at the same expense per acre. In 1855 I was induced to use as an experiment four different kinds of manures for Swede turnips, three of which I purchased from three eminent manufacturers of turnip manures. I shall classify them as No. 1, No. 2, and No. 3. They were all drilled at the same time, with Swede seed, and at the same expense per acre, in competition with guano. The swedes drilled with the three first-named came up, and made equal progress up to the time of the first hoeing; the guano swedes, when they made their first appearance, looked stunted in their growth, and anything but promising, and were much more injured comparatively by the turnip-fly, than those drilled with the three other manures. They were not ready for hoeing for at least one week after the three first-named, which I attribute to the seed not having come in contact with the guano, as a preventive from injury to the germination of the seed. The result was that in the month of August, the progress made by the swedes with all four manures, was about equal in appearance; in the latter part of November, No. 1 and No. 2 swedes were about equal in weight; No. 3 were not so good; but the guano swedes were about three tons per acre more in weight. In 1856, in order to test the relative merits of Peruvian guano as compared with bones, a friend of mine drilled sixteen bushels of bones per acre and I two cwt. of guano, the land being about the same in quality. In the latter part of November the guano swedes were full three tons per acre more than those drilled with bones. In 1857 I wished again to try the relative merits of the same (Nos. 1, 2, and 3, and guano) at an equal expense per acre. All these manures were then used on pieces of land of the same value, and drilled in rotation at the same time with rapeseed. The result was that Nos. 1, 2, and 3 took the lead at first, and the guano rape was not so flourishing; but after the first hoeing of the three first-mentioned, the guano rape gradually overtook that

drilled by the three other manures, and when my sheep began to feed the rape in the latter end of July, it was quite palpable that the guano rape was doing the best. After my sheep had been feeding the rape about a fortnight, the rape drilled with the three first-named manures began to show mildew; the rape with the guano was growing luxuriantly without being much affected by mildew, and at the end of six weeks I considered that I had one-fifth more feed per acre after the guano rape than after that manured with Nos. 1, 2, and 3. In consequence of my wishing to try the relative merits of guano in competition with farmyard dung, my sheep fed a piece of early tares and were folded on the land, after which I put a heavy dressing of farmyard manure. One part of the field was left for guano, which I drilled at the rate of two cwt. per acre without farmyard dung. The result of this experiment proved the guano turnips to be much the best. The first time that guano was used in its pure state without any mixture of ashes for turnips, the crop was destroyed, in consequence of the seed coming in contact with it, there not having been a sufficient quantity of earth allowed to cover the manure previous to the depositing of the seed. Having lost my crop of turnips, which was a few acres only, I was induced to re-sow the land with rape broadcast, the seed being covered lightly with the hoes in preference to ploughing, as I wished to keep the manure on the surface. The rape came up with a good plant; but I soon perceived that it grew in rank, just as the manure was drilled; and by the time it was ready for hoeing, where there was no guano drilled, the rape-plant died gradually away. I have mentioned this, because I think it affords another striking proof of the great value of guano. I am sure I may say that during the last three years I have not lost an acre of turnips from the fly where guano has been used; nor have I sustained any injury from the effects of guano, except on three or four acres where I first drilled it in its pure state. Having now, I think, said enough as to the advantage of guano, and shown plainly that in every instance guano has had the pre-eminence, so far as my own experience has extended, I shall now, gentlemen, make a few remarks on the application of guano. In reference to the best system of applying guano for root crops, I certainly advocate the use of the drill in preference to sowing guano broadcast, although on many farms that method is adopted with success, as a means of preventing injury to the germination of the seed—that is, on lands where the ridge-system is practised. The farm in my occupation being best calculated for the drill-system on the flat, I shall confine myself to that mode of application, which, from practical experience, I have found to answer the best. With regard to drills, we have a great variety in use. Many of them I consider very good for drilling artificial manures; but, as economy in horse and manual-labour is a great item in the farmer's expenses, I wish to show that the drill which I have been using, and which was manufactured by Messrs. Reeves, of Bratton Westbury, has many advantages. In 1857 I used Reeves' patent drill with great success. As respects economy, guano can be used either with or without a mixture of ashes. At the same time, I should recommend two bushels of dry ashes mixed with 2 or 2½ cwt. of guano to the acre, which Reeves' drill will distribute with a regularity quite equal to that of any other drill that I have ever used with twelve bushels of ashes. On a farm where the land is somewhat level this drill will with two horses put in nine acres per day, and the same horses will take the manure with the drill for a day's work. I always give one turn with the harrows after the drill, to cover the seed. I should state that the principle of this drill is to deposit the guano, allowing a sufficient quantity of earth to cover the manure before the seed is deposited, which prevents the guano from burning the seed. This drill may be used with equal advantage in drilling guano or superphosphate, either with or without ashes. Our friend Mr. Nesbit, in his admirable work on Agricultural Chemistry, mentions that in drilling guano for root crops it is necessary that the guano should be mixed with four or six times its weight of ashes, to prevent it from burning the seed; but, with all due respect for Mr. Nesbit's valuable information respecting the mixture of ashes with guano, I trust I have shown plainly from my experience that two bushels of dry ashes per acre is a sufficient quantity to be mixed with guano or superphosphate. I hope I have also shown that the drill which I have used is most economical and advantageous. In conclusion, I must confess that my object in introducing this subject has been rather to glean information from the discussion than to give the results of my experiments. I now thank you for your attention, and I shall be happy to answer any questions you may feel disposed to ask me on the subject (cheers).

Mr. J. THOMAS (Blestoe) wished to ask Mr. Sainsbury what quantity of ashes he had been accustomed to use to a cwt. of guano?

Mr. SAINSBURY said he had been in the habit of using two bushels of dry ashes to 2½ cwt. of guano.

Mr. KING: What drill do you use?

Mr. SAINSBURY: Reeves's.

Mr. COUSSMAKER (Westwood, Surrey) wished to make a few remarks founded on his own experience. He had not used artificial manures to a very large extent, having always acted on the maxim, which he learnt a good many years ago, from a gentleman in Northamptonshire, Mr. Hildyard, that a good farm, like a good joint of meat, only required basting with its own dripping. Having kept plenty of stock, he had generally been able to manure his farm with farm-yard dung. He did not mean to deny that artificial manures might be used advantageously in many instances, and especially when a farmer took a farm which was not in good order; but when a farm had been got into good order, it would not, in his opinion, require much artificial manure. With regard to the relative merits of different kinds of artificial manure, he quite agreed with Mr. Sainsbury, that guano was the best of all (Hear, hear). He happened to live in the neighbourhood of Aldershott, where there had been started a new manure, derived from the camp—animal carbon, or whatever they pleased to term it. He was induced to buy a certain quantity of this manure for the purpose of trying it against guano in money value. Having given £7 per ton for this Aldershott manure, and £14 for guano, he used twice as much of the former as of the latter, and the result showed that guano was decidedly superior to the new manure (Hear, hear). His experience with regard to guano proved that, if they entirely depended upon it, they would force the plant very much in its early stages, and afterwards leave it in the lurch (Hear, hear). He thought the best application was a half-dressing of guano with a half-dressing of farm-yard dung. If he had to manure for roots, he would not apply farm-yard dung to half the land and guano to the other half, but would put a half-dressing of each on the whole of the land, experience having convinced him that that was the best mode of proceeding. Mr. Sainsbury had mentioned the drill system; he (Mr. Coussmaker) had always sown his guano broadcast. In so doing, however, he had met with one great disadvantage, and he would be very much obliged to any gentleman who would suggest to him a

remedy for it. Guano was of a very light and volatile nature, and if, when sown broadcast, there happened to be much wind stirring, it was blown to a part of the land where the farmer did not want it to be deposited; or, if the locality was near one of the extremities of the farm, it fell, perhaps, on a neighbour's land instead of his own. He had mixed it with ashes, and occasionally with salt, in order to insure a more certain and equable distribution; but that had not always secured the object. He had thus been led to water it, and he wished to know whether his doing so deteriorated the quality of the guano. He had, in fact, never been able to distribute guano as he wished to do.

Mr. J. HOWARD (Bedford) observed that it was very evident that Mr. Coussmaker had not a broadcast machine, as that would have enabled him to drop the guano immediately on the surface.

Mr. R. BAKER (Writtle) said he had not many remarks to offer on this subject, feeling, as he did, that Mr. Sainsbury knew much more than he himself did with regard to the application of guano. Still there were some points connected with the use of guano which he would proceed to mention, especially as it might easily be subjected to the test of experiment. He had before observed in that club that in his opinion guano should never be applied, either for turnip or for mangel wurzel, immediately before the depositing of the seed. For applying it for turnips he had ploughed it in immediately, and let it remain for ten days or three weeks, or whatever time was required: in the first instance he ploughed it in with a surface ploughing and afterwards with a deeper ploughing, and by that means it became thoroughly incorporated with the soil, and acted in the most beneficial and regular manner, none of its constituent properties being lost. During the turnip-sowing season he had frequently had indicated to him a piece of land where guano was used by the smell a quarter of a mile before he reached the spot. Of course where that was the case a very large proportion of the guano was taken up by the air, and entirely lost to the crop; whereas, if the guano had been ploughed in immediately after it was deposited, and had thus become fixed in the soil, none would have been lost. When guano had once become incorporated with moist soil, no subsequent exposure to the action of the atmosphere would cause it to evaporate. That was a very important point to bear in mind. As regarded the beneficial influence of guano, experiments were often very fallacious. The result of an application of guano depended very much on the state of the weather at the time when it was applied. If there were not sufficient moisture to fix it in the soil at once, it was far less beneficial than it would otherwise be. In reference to its application by sowing or drilling, he must observe that he had not got a broadcast machine; but he sometimes sowed it with a manure-drill, and ploughed it in immediately, which prevented the wind from blowing it about. When sown it should be incorporated with some other substance. He sometimes used decomposed sawdust with it; if salt was desirable for the land, he used it with that; and he generally combined it with wood ashes, or some other substances, in order to prevent it from being taken off into the air. It was well known that guano was much more beneficial to land which comprised a large quantity of loam or clay than to gravelly soils; the reason being that when it was incorporated with loam, it was immediately fixed, whereas if used in gravelly soils, it was very apt to be carried off. Having used guano for a great many years, he must pronounce it to be, in his opinion, the cheapest manure that could be employed—especially for root-crops. Whatever might be the case with regard to corn-crops, for turnips and mangel-wurzel it was undoubtedly the cheapest manure they could use, notwithstanding the high price of it. He had been led to the belief that a large portion of the beneficial qualities of manufactured manures consisted of guano in another form (Hear, hear). About a week ago, a person asked him to purchase some manure, and in so doing said—"We have two kinds of manure, turnip-manure and corn-manure; but the latter contains twice as much guano as the former." The price of the one being £1 more than that of the other, then what was the advantage of buying the cheaper article, when you must apply two tons instead of one? (Hear, hear.) He wanted to get, if possible, a cheap manure; but so far as his experience enabled him to judge, there was, in fact, no cheaper manure for root crops than guano. (Hear, hear.) His opinion was, that for ordinary use there was nothing so cheap, and nothing so beneficial in the production of root-crops, as guano; but its beneficial application must, he maintained, depend very much upon the state of the weather and the soil, and upon the mode of application.

Mr. KING (of Beedon) wished to know what amount of guano he considered a sufficient dressing when he did not use any farm-yard manure?

Mr. BAKER did not hesitate to say that guano might be applied liberally for root crops, but when applied to corn crops any quantity beyond 2 cwt. per acre produced comparatively with the increased cost but little benefit. He thought 2 cwt. per acre was the maximum that should ever be applied for corn crops, and that for root crops that quantity would yield a better return in proportion to the cost than any additional quantity. Some years ago Mr. Vernon made some experiments, the results of which were published in the *Gardeners' Chronicle*. It was there shown that 2 cwt. was all that could be usefully applied for corn crops; that although a larger application might yield an apparent advantage in the foliage and so on, still when the produce was put in the bushel, or weighed, the increased outlay was not justified by the result.

Mr. J. THOMAS (Bletsoe) said, he had been in the habit of applying guano for several years past. He had invariably applied it with farm-yard dung. He generally cultivated his turnips on the Northumberland or ridge system, putting a fair quantity of farm-yard dung, then sowing the guano broadcast, and reversing the ridges. He usually mixed about 2 cwt. of coal ashes—having a steam-engine of his own he found this mixture economical—with about the same quantity of guano, and also about 15 or 16 tons of farm-yard manure. He had on two occasions tested guano by a comparison of it with blood manure, and on his turnips, produced with the aid of the two, being weighed separately, he found very little difference in money value between blood manure and guano. He did not concur, however, in the observations which had been made to the effect that whatever might be the price at which guano was sold, they must have recourse to it, and it alone; for he thought that would depend on the price at which they could obtain other artificial manures (Hear, hear). He perfectly agreed with Mr. Baker, that guano answered better on clay land than on gravelly land. Having a portion of each on his own farm, he had invariably found the greatest effect from guano on the clay. Some allusion had been made to bones. Now on grass lands he had used as a manure a mixture of bones, guano, and salt, at a cost of 50s. per acre. He had also used guano by itself, and bones by themselves, but the mixture had answered best. In some counties it was quite proverbial that bones were preferable to everything else; but in Bedfordshire he had found the best application to be a mixture of bones, guano, and salt. In growing mangel-wurzel, particularly on land recently broken up, or broken up within

ten years, an admixture of salt with guano in the right proportion was a very great advantage. During the last two years he had used an equal quantity of salt and guano, and he had in consequence found his produce considerably larger, and the result more satisfactory in all respects than was the case before. Perhaps on stiff and heavy clay land such a mode of application might be open to objection; but where the land was porous an admixture was, in his opinion, very beneficial.

Mr. J. THOMAS (Lidlington Park, Ampthill) wished to make a few remarks in reference to this subject. First, with regard to the maxim cited by Mr. Coussmaker, that a farm ought, like a joint of meat, to be basted with its own dripping. It was true that under certain circumstances a farm should be left to provide its own manure; but if by an application of extraneous manures it could be cultivated more profitably than without them, it ought not to rest contented with the course of proceedings followed in reference to a joint of meat (Hear, hear). It was a matter of calculation to the skilful farmer how far any outlay upon foreign manures would be recompensed by the return which he would obtain for that outlay. (Hear, hear). He had no wish to enter at any length upon the use of guano for corn crops, because the question stated on the card had reference solely to root crops; but this might be laid down, he thought, as a general rule, that if by laying out £1 they could obtain £1 5s., the money would be exceedingly well laid out; whereas, if by laying out £1 they could, in consequence of the low price of corn, only secure 15s., the money would be very badly laid out. (Hear, hear). If they expended an extraordinary amount of money in the production of corn crops, it was, of course, in the hope of being remunerated in the sale of the crops. They all knew that when the market for manufactures was glutted, the manufacturers, instead of continuing production at the same rate as before, made their operatives work short time till the market was relieved; and so with regard to corn crops, it was, he thought, unwise in the agriculturist to lay out his money to increase his production when the market was already so glutted that he had great difficulty in disposing of what he had on hand. Dismissing, however, from his mind the subject of corn crops, he now approached the question on the card, namely, "The advantages of guano for root crops, and the best system of applying it without injury to the germination of seed." The first point which occurred to him was the portability of guano—a very important feature in its applicability to the land. This enabled the farmer to scatter manure over the farm at the minimum expense for carting. The farm-yard manure might be applied nearest home with half a dressing of light manures, while the more portable manure was conveyed to a distance. As regarded the best mode of applying guano for root crops, he should not speak without the book, having been a very large consumer of guano for many years. He had found it the greatest use in the growth of mangel wurzel, and in Bedfordshire, where the land had got so exceedingly sick of Swedish turnips that they could scarcely rely upon them at all, it was becoming more and more the practice every year to grow mangel wurzel upon lands which were formerly under ordinary circumstances cultivated for the turnip crop. He would now tell them what course was adopted there, and it was a course by which he had never failed to obtain a large crop of mangel wurzel. He always endeavoured to get his land into good tilth, and this object he secured by means of Coleman's cultivator, which he believed to be the best. Having the stetches made 27 inches apart, he mixed two cwt. of guano with two cwt. of salt; or whatever might be the quantity of guano, he used an equal quantity of salt, in order to prevent that distribution over the neighbourhood which had been mentioned by a preceding speaker (Mr. Coussmaker). What he was now about to mention might appear a very operose proceeding, but it was always fully justified by the result. He set a man to sow the mixture of salt and guano under hand, as it were, down the different stetches, in order that none of it might be carried away by the wind. After that the stetches were reversed, being rolled down with a heavy iron roller. Experience had convinced him that the more solid the land could be made for mangel wurzel, the more reliance they could place on the subsequent crop, and the heavier would be the weight per acre. He believed, that all who adopted this method of growing mangel wurzel, using an equal quantity of salt with guano, sowing the mixture under hand in the stetches, and afterwards reversing the stetches, would secure a very large crop. He never used any farm-yard manure for root crops, it having been shown by the experiments of Liebig, Mr. Lawes, and Mr. Nesbit, that when this fertilizer was used for crops of corn the phosphates remained for the future crop of roots without being at all deteriorated. He trusted he should be excused for having stated thus minutely his own practice—a practice which, he would add, had always resulted in success. (Hear, hear.)

Mr. HARRISON (Clifton Hampden, Oxon) felt compelled to differ to some extent both from Mr. Sainsbury and from Mr. Baker: from the former, inasmuch as he advocated the application of guano in its pure state to the soil, without mixing it with any other material; and from the latter, inasmuch as he was in favour of sowing it in its natural state broadcast. As regarded Mr. Sainsbury's mode of application, he thought that, as guano was such a very powerful substance, there was great danger of its killing the seed if brought in such close contact with it; while as respected Mr. Baker's plan, he was of opinion that, as guano was such a very expensive article, instead of sowing it broadcast, they should endeavour to lower the rate of cost by mixing it with other articles. His own plan was to reduce by five or six times its natural weight, by mixing it with sand or mould, and in that state to drill it in with the seed. He believed that, with the present price of the article, that was the only mode of securing an adequate return.

Mr. SAINSBURY wished to say one word in reference to what they had just heard. He knew from experience that guano could be applied unmixed with ashes without at all injuring the seed. One bushel of ashes to a cwt. of guano might appear a small quantity; but it was, in fact, an ample proportion: he had used it year after year.

Mr. E PURSER (New Bridge-street, Blackfriars) said they had heard that evening the opinions of several practical farmers: he appeared before them as a dealer in and manufacturer of manures. They were all agreed as to the value of guano as a manure for root crops; but, as a seller of manures, his chief business from the month of April to the month of June lay in superphosphates; and he believed that for the thinner and weaker soils superphosphates were extremely valuable in combination with guano. He was now giving them the experience of his office with regard to operations extending over nineteen years. Year after year he found superphosphates in increasing demand for root crops, and for one ton of guano he now sold three tons of superphosphate of lime. If farmers used things that did not pay, it was not his fault; and, on the other hand, he would not pretend to set up his own experience against the practice of the gentlemen present. He had a very extensive connection with Ireland; and in that country, where rain was nearly always falling, superphosphates, as an addition to guano, were found invaluable. In short, these manures were making their way to a much greater extent than the meeting appeared to have any idea of. They all con-

tained bones, in a soluble state. He had watched the action of manures in the county of Sussex, where also he had a very large connection, and he had found that for root crops the demand in almost every instance was for bone manure, with an addition of one cwt. per acre of guano on the weaker soils.

Mr. MARSH (Sandwich, Kent) said, having sold a great deal of manure, besides having been a farmer for many years, he could fully bear out Mr. Purser's observations. Where he had of late sold one ton of guano he had sold three or four tons of superphosphate of lime. He sold a great deal of manure in the neighbourhood of Dover, and any gentleman who had seen the hills in that locality must feel how enormous would be the expense of carting ordinary manure in that part of the country. He had there found that a mixture of a small quantity of guano with superphosphate was the best manure that could be applied for turnips.

Mr. J. C. NESBIT said, he wished to make a few observations on this subject, especially as it was one which he had to some extent studied. In the application of guano they must have regard not only to the mode of application and to the roots for which it was to be applied, but also to the quality of the soil. The quality of the soil often made a very great difference as regarded the result. He thought that every practical farmer present would acknowledge that, as a general rule, guano was much more valuable in soils which were deficient in organic matter than in soils naturally rich in that material, or which had received, by feeding sheep or cattle, large quantities of oilcake, and other similar matters, and which had been cultivated for a considerable time. Upon poor soils guano acted most powerfully, not only yielding an increase of fifty to one hundred per cent. in the root crop, but also leaving a large amount of ammoniacal matter undecomposed for the subsequent crops. The idea was pretty general that guano, if sown in a dry state, would not act. They need not, however, be particularly alarmed about any loss in their fields arising from drought, or even from moisture, though the former might affect the particular crop to which the guano was applied. They might lose as regarded a particular crop, but the guano would still be in the soil, available for the next crop. As to the effects of moisture, he had in two or three cases analyzed specimens of the cargoes of guano vessels which had been wrecked. In the case of a wreck which occurred near Liverpool, the cargo was subjected to the influence of the tide for five or six days, and on examining some of it he found that it had only lost two per cent. of its ammonia. In another case, which occurred at Falmouth within the last two months, a vessel, with 2,400 tons of guano on board, having sunk in five fathoms of water, some of the manure was dredged up, and sent to him for analysis, and it gave 13½ per cent. of ammonia. Guano, on the average, contained 16 per cent. of ammonia; and in the first case which he had mentioned the loss was only 2 per cent, and in the second 2½ per cent. With regard to the application of guano for root crops, it would, he believed, be found best to unite with it some other substance. In a little work which he published some time ago, he remarked that, when guano was used alone, it ought to be mixed with four or five times its weight of some other matter. The first time that he ever saw a field sown with guano was in 1843. A friend of his, in Kent, then sowed twenty acres of turnips with guano, and did not get a root, as the guano was drilled with the seed, and killed it. It was subsequently cross-drilled, and a good crop was the result. My friend subsequently altered his drill so as to deposit the manure about two inches below the seed, and he then succeeded in getting good crops. The guano, however, was mixed with mould, or wood and peat ashes. He believed that, as a general rule, the best way of using guano for roots was to sow it broadcast, and to harrow it in. If the ridge system were adopted, as was recommended by Mr. Thomas, it ought to be broadcasted over, and then the ridges formed ("No," from Mr. Thomas, of Lidlington, and Hear, hear.) He spoke in accordance with his observation. He had seen it applied in that way, the ridges being flattened, and the turnip seed drilled with superphosphate of lime; and he must say that, in his opinion, broadcasting with guano, and drilling with superphosphate of lime, was the best plan that could be adopted. There could be no doubt that, for mangel wurzel, guano was preferable to superphosphate; though, in that case, he should recommend the use of 6 cwt. of salt per acre. He would also recommend that a certain proportion of some superphosphate should be drilled in with the seed, and at least 5 cwt. of guano broadcasted per acre. The effect of the superphosphate was to bring the plants earlier to the hoe; and the guano supplied the subsequent nourishment. If manure were confined solely to the lines of the drills, the lateral roots did not get their proper amount of nourishment. It could hardly be necessary for him to refer to the use of guano for cereals. Everyone knew that for them it was the best manure that could be got. Ammonia must be had; and there could be no doubt that, even at present prices, guano was the cheapest form in which ammonia could be obtained (Hear, hear). With regard to rape, he had found that a fairly soluble superphosphate would do better than any other manure. It would perhaps be recollected that about two years ago he lectured to the club on the subject of superphosphate of lime. On that occasion he was rather taken to task for maintaining that the use of too large a quantity of soluble phosphate of lime was undesirable for root crops. He had been very much opposed in that view by many parties. Now he would take this opportunity of stating that all the experiments which he had made since, and all that he had learned from others, confirmed him in the opinion which he then expressed against the use of too large quantity of phosphates in a soluble state. In many parts of Norfolk, Essex, and some other counties of the same geological character, soluble phosphates might perhaps be used in considerable proportions, without any great disadvantage; but if they went westward, to districts where there was a smaller amount of calcareous matter in the soil, they would find that those manures which contained a proper proportion of insoluble phosphate bore away the palm. He might mention that even at Holkham some experiments had been tried, the result of which was that the largest amount of roots was produced by the manures containing the greatest proportion of insoluble phosphates; a manure which contained nearly 28 per cent. of insoluble, and only 6¼ per cent. of soluble phosphate, produced the largest crop. One of the most celebrated manure makers in the country came in only seventh in the race. He had thought it right to make this statement, in order to show that the views which he before expressed were not the result of mere hearsay, but were formed from experience. They had, he believed, been corroborated wherever their correctness had been subjected to a practical test. The insoluble phosphate if possible ought to be fine bone.

Mr. J. HOWARD said, having seen guano sown broadcast he must declare that he did not know a nastier job than sowing it by hand, or an operation more likely to give a man the cholera (laughter). He had also seen it applied with a machine, and having no interest in broadcast machines, being neither a manufacturer nor a vendor of them, he must declare his belief that as regarded equability of dis-

tribution and freedom from loss by being blown away, the use of a machine contrasted most favourably with sowing by hand. He was aware that a broadcast machine was not a common thing on the farm; but he believed that if the gentlemen around him would inquire carefully into its use, it would soon become a standard implement.

Mr. T. W. GRANGER (Stretham Grange, Ely), said he had used two machines, one made by Messrs. Garrett, of Saxmundham, the other by Messrs. Holmes, of Norwich; both of which would spread in the most level and even manner from 3 to 100 bushels per acre. He thought so well of Messrs. Garrett's machine at the Carlisle Meeting, that he purchased one, and has used it constantly since to his perfect satisfaction.

Mr. NESBIT, adverting to the remarks of Mr. Coussmaker, observed that it was very easy to mix guano with such an amount of water as would prevent the wind from blowing any of it away. Having seen the machines mentioned by Mr. Granger at work, he could bear testimony that they distributed manures beautifully, and in any quantity that might be required.

The CHAIRMAN, in closing the discussion, said he need scarcely remark that he concurred in what had fallen from Mr. Sainsbury with regard to the value of guano as a manure. He thought, however, that very great risk attended the application of it at different seasons and on different sorts of land. He recollected that the first time he ever used guano it was in the second or third year after it was first imported. He drilled 3 cwt. per acre with his seed on the flat, and the consequence was that he lost his crop; that convinced him that drilling it was not the most desirable mode of proceeding. The next year he looked right and left among his neighbours for information, and he then found that the best system was that of sowing guano broadcast; that system he had followed ever since. He had always sown an equal weight of guano and salt; and had taken care to sow, if possible, on a moist day—a condition on which the ultimate benefit greatly depended. On one occasion (a dry season) he sowed on a damp morning, expecting rain, which happened to be followed by very dry weather, and the result was that he lost a considerable portion of the manure. As regarded the application of guano with the seed, the machine mentioned by Mr. Sainsbury might comprise all that was required. He fully concurred in the opinion that a mixture of guano with some other substance was the best application for root crops. In conclusion, he would again express a hope that they would soon see guano sold at a lower price.

Mr. J. THOMAS (Lidlington Park) said, he should be sorry if it went forth to the world that they had then heard for the first time in their lives of such a drill as had just been referred to. A quarter of a century ago it was the common practice in Bedfordshire, when a light dressing was used, to put the dressing in to the depth of about three inches, after which there followed the hoe or rake that covered up the manure, and after that, again, the coulter that deposited the seeds of the mangel-wurzel.

Mr. SAINSBURY then replied: Adverting to the last remark of Mr. Thomas, he said he did not dispute that there was a drill in use five-and-twenty years ago; but the drill which he had described was of a different description: the work was done without the assistance of a rake to cover the manure. He took it for granted that the drill to which Mr. Thomas referred would not drill guano or superphosphate of lime in a pure state; whereas, that which he used would deposit 2 cwt. or 3 cwt. of guano either with a bushel of ashes or without them.

On the motion of Mr. GRAY, seconded by Mr. R. BAKER, a vote of thanks was accorded to Mr. Sainsbury for his paper; and,

On the motion of Mr. THOMAS, of Lidlington Park, seconded by Mr. CONGREVE, thanks were also voted to the Chairman.

This terminated the proceedings.

THE TRIAL OF THE STEAM-PLOUGH AT SALISBURY.

People who would have had Milo make his first essay with a full-grown bull—who teach infants their first steps upon the debris of a hard-baked fallow—and who think the earliest steam-carriage should have attempted a miry clay lane—such reasonable individuals are content for the steam-plough to break its shares among the ungrubbed roots of a felled forest, or strike fire on the flints of Salisbury hill. But for our own part, we would urge upon the Council of the Royal Agricultural Society the desirability of selecting a tolerably level field of average friable loam or clay devoid of big boulders, for the ensuing trials at Chester. Rely upon it, the season in which the work has to be performed will of itself operate against the action of the implements so as to render the ploughing sufficiently difficult.

If the Society defrayed all expenses of the exhibitors, a trial like that at Salisbury would merely stultify the inventors, disappoint the great concourse of visitors, inflict the reproach of public disgust upon the whole subject of steam-tillage, and egregiously waste the funds of the members. But when the exhibitors are invited to compete for the reward of their long toil and ruinous outlay of capital, to bear very heavy expenses in preparation and competition, and are then fixed in a situation where no fair display of their capabilities is possible, they may certainly consider themselves hardly used. However, we are all willing to "let bygones be bygones," and to regard the Royal Agricultural Society's business with a kindly spirit, only let it treat us more considerately at the coming meeting.

Let us now record what the judges and stewards say of the matter, in the Society's own Journal. Messrs. Clarke and Owen say: "The ground was altogether unsuitable; the soil was very shallow and unusually flinty; and the summer's drought had so hardened it, that it was with great difficulty that the ploughs in the upper part of the field could be made to enter it at all. The site also of the field, upon a hill of considerable elevation, occasioned great difficulties and delay." The senior steward, Mr. Wren Hoskyns, says: "Such a soil, in such a situation, hardened to such a condition not only by its own flinty nature but by the long-continued influence of one of the most extraordinary seasons that has ever been known, were enough to render any trial practically abortive." And again: "It was upon this elevated spot, accessible only from a narrow road by a still narrower turning, very steep, and partly over soft fresh-cultivated ground, that the steam-ploughing was to come off, if at least it could ever come on." Re-

specting the question—Whose fault was it that such ground was provided? he adds: "The temptation of an unenclosed space of eight-and-thirty acres for these trials can hardly be called the inducement of the Society to accept the offer of such a spot, because *there was no other choice;* but it is to be hoped that, in all future negociations with the towns or localities at which the summer meetings shall be held, the very ample area required for this class of trials will be regarded as a preliminary condition." And, after referring to the abominably difficult road leading to the field, he concludes: "Still the judge and stewards had no choice in the matter; and it is only to be hoped that they may never be called upon to exercise their duties under the like circumstances again."

Mr. Smith, of Woolston, would not exhibit at Salisbury. Mr. Williams, of Baydon, finding what sort of place had been provided, objected to such a trial altogether, and endeavoured, as we believe, to persuade his brother-exhibitors to refuse to mock the public and injure their own credit by entering upon a hopeless task. Mr. Collinson Hall, Mr. John Fowler, jun., Mr. Charles Burrell, and Mr. John A. Williams have now addressed the Council on the subject, complaining of the past, and offering suggestions for the future. In considering this petition or manifesto, let us bear in mind the official statements with regard to their several machines, and the results of the trial.

Inadequate and faulty as the experiments were, Mr. Hoskyns acknowledges "the admirable docility and power of Mr. Boydell's (Burrell's) traction-engine;" and says further, "No one, who saw the work performed, even under these adverse circumstances, by Mr. Fowler's plough, could doubt that, in his case at least (not to the least disparagement of the other competitors), steam-*ploughing*, as such, had attained a degree of excellence comparable in point of execution even with the best horse-work. As to the relative economy, there seems little reason to doubt that the calculations arrived at by Mr. Amos and others the year before, at the adjourned trial at Boxted Lodge, were sufficiently near the truth to leave *a very inconsiderable difference in favour of horse-work.*

Five of the judges report that Mr. Boydell "triumphantly ascended the hill to the ground laid out for ploughing, and fully proved his power as a traction-engine. He shortly commenced ploughing; but this was not satisfactory, for nothing could keep the ploughs in the ground." Mr. Collinson Hall is praised for the "strenuous and laudable" efforts which — with great cost — overcame the shameful obstructions on the road, and "succeeded eventually in bringing up his engine, and making good work." Mr. Williams's system is "anything but satisfactory;" and his personal conduct described as objectionable. We suppose in consequence of his being unable to restrain his indignation, and manifest the sublime patience which characterized Mr. Hall, in spite of repeated vexatious accidents. The work done by Mr. Fowler is declared to be "very good; but here we must say we could not reduce the price per acre below that of the Boxted trials. As far as ploughing is concerned, we think Mr. Fowler's arrangement of his ploughs is the best we have seen. As judges we wanted very strict data to recommend the steam-ploughing to the public; we are sorry we cannot do this, though we think Mr. Fowler still stands pre-eminent over any others. We cannot say that his ploughs are 'economical substitutes for the plough or the spade.'" Considering the great ability shown, and the great expense incurred by Mr. Fowler, they recommend the Council to "vote him a medal."

Two other judges, in a separate report, say, "the object to be accomplished was a more economical mode of ploughing than could be done by horse-power. For ourselves we were at once convinced that no satisfactory decision could be arrived at..... Sufficient was shown to convince us that Mr. Boydell's engine is one of no ordinary merit, and capable of very useful and extensive farm-service..... Mr. Fowler's plough performed its work very creditably, under all the circumstances of a hard soil and much obstructing company. The ploughing was effected in a truly husband-like manner, and at a depth not generally reached on such soils. The work was fairly laid, and worthy of comparison with that done alongside it by one of Howard's ploughs in the hands of a first-rate ploughman." Mr. Williams's ploughs, they say, did not work well; and "the compact form and most ingenious adaptation" of Mr. Hall's engine met their approval. They conclude that only "a proper time and suitable soil" are needed to prove that the steam-ploughing can be accomplished in "an efficient and economical manner."

It appears, then, that the only ploughing which was quite satisfactory in point of *quality*, was Mr. Fowler's; and, could the working expenses have been estimated at a very small trifle lower, the work would have been pronounced also "economical." As far as they could tell, the judges made out the cost per acre to be *nearly, if not quite*, as low as by horse-labour.

Now, we have over and over again insisted that the mere working at a trifle less expense *per acre* does not constitute *the main element of economy or saving in a steam-plough;* and it is here that we think the judges have been shortsighted. Indeed, after all, the public may conclude that Mr. Fowler's plough (on the stewards' and judges' own showing) *is* an "economical substitute" for the horse-plough.

Everyone will surely admit that an "economical substitute" for the plough is something that it will pay us better to have, that can produce more valuable results for a certain amount of money. Well, if the steam and the horse-plough both work at the same price per acre, there is the item of *time*, the greater extent of land ploughed in a day, which at once makes the steam-plough the cheapest and best worth having.

The main value of Mr. Smith's steam-scarifiers and cultivators is not in the low price per acre, but in the great quantity of land broken up and cleared in a short time just at the critical season. And taking the acreage cost of work by Fowler's steam-plough and the common horse-plough to be about the same, Mr. Hoskyns says: "If this be true as a comparison merely taken acre for acre, or hour for hour, every one who knows the supreme value of *time* in the autumn months on clay soils, and the difference, in capacity of *day-work*, between a horse and a steam-engine, must be aware that a new multiplier at least of 2, if not more, may be placed to the credit of the steam-engine, regarded as an available power or auxiliary when work is pressing, and when, according to a well-known poetical authority, the best or rather only method to lengthen the shortening days is to "steal a few hours from night." Yet the judges seem never to have considered that, when a steam-plough can work for, say 7s. 2½d. an acre, and horse-ploughs for 7s., the steam-plough may be better worth having (therefore "more economical") than the horse-plough; and this, indeed, is one of the principal points in favour of steam-tillage at all. There is also another element of considerable consequence in the comparative economy between steam and horse power cultivation. It has become matter of experimental proof, upon certain classes of clay soil, remarks Mr. Hoskyns, that "the liberty of a more perfect selection of season, and condition of soil for cul-

tivation, and the absolute, and, so to speak, *repeated* avoidance of the tread of horses, year after year, brings about a permanent and almost constitutional change of character in the mechanical structure of such soil:"—Besides, that the produce on steam-ploughed land has been found in many cases to exceed that of ground ploughed by horses; not only the depth, but the very shaking and disintegrating of the furrow-slices giving a higher degree of pulverization, which promotes active fertility.

We have repeatedly enforced these and other considerations upon the attention of those called upon to weigh the merits of the steam against those of horse ploughs; and, seeing that a (supposed) *very minute excess of actual acreage cost* has been allowed by them to counterbalance all the great benefits accruing from rapid autumn-cleaning and unusually deep working by steam-power, we do not wonder that the above exhibitors feel constrained to appeal to the Council for information as to how and in what light their inventions will be judged next July. Their address must receive some further notice.

ORIGIN OF DURHAM SHORT-HORNS.

SIR,—In your journal of the 22nd of March, alluding to the sales of shorthorns about to take place and now coming off, you say that at one of them, namely, that to take place on the 21st of April, several animals will be offered which are right line descendants through females of the celebrated cow "Favourite," bought by the Messrs. Colling, of Mr. Maynard of Eryholme, and by them christened "Lady Maynard." This mention of "Favourite" and the Colling's stock brings to my recollection a discussion introduced a few weeks ago in the agricultural article of the *Economist*, on the origin of the improved Durham shorthorns, suggested by the publication in a contemporary, the *North British Agriculturist*, of extracts from a journal of the late Major Rudd, of Marlow, in Yorkshire, called "An account of some of the shorthorn stock, late the property of Mr. Charles Colling, of Ketton, in the county of Durham."

As I think these extracts may be interesting to some of your readers, and as I have not seen them elsewhere, I have transcribed them, and have at the same time ventured to send you some observations on the origin of the improved Durham shorthorns. In making them, I may be permitted to say, I do so as a Durham man, with a perfect knowledge of parties and localities, myself for upwards of twenty years a breeder of shorthorns, and one who has long and diligently investigated the subject. I am especially induced to do this at present, because I have of late frequently seen the matter discussed by strangers with an interest that may well put us lukewarm natives to the blush; but in which discussions, as might perhaps be expected, we hear assertions made that to us, who are "to the manner born," are not a little astounding.

Speaking, then, in the character in which I have represented myself to do, I have long since arrived at the conclusion, wherein I entirely agree with the writer in the *Economist*, that, in forming the improved Durham shorthorns the Messrs. Colling proceeded, *generally*, "by care and selection from the local breed of shorthorns which had already attained considerable perfection," and not by crossing distinct breeds of cattle. I am bound, however, at the same time to say that he is mistaken in alleging that "the story of the brothers Colling having used a cross of Galloway blood in the improvement of their shorthorns has no foundation in fact." It is indisputably true that Mr. *Charles* Colling had recourse to such a cross in one family of his shorthorns, which is known, technically speaking, as "the alloy;" to which I shall take occasion particularly to advert, and in so doing it will perhaps be seen why we find "no trace of such crossing in Major Rudd's journal."

The following are the extracts from that journal to which I have alluded:

No. 1. Old Favourite, was bred by Mr. John Maynard, of Airyholme-upon-Tees. She was got by a shorthorned bull belonging to a Ralph Alcock, who lived near Airyholme, which bull was remarkable for his nice handling. The dam was got by a shorthorned bull belonging to Mr. Jacob Smith, of Givendale, near Boroughbridge. Her grandam was a beautiful roan cow, called Strawberry, bred by Mr. Maynard's father, and got by a shorthorned bull belonging to Mr. Polly, of Worrall, then held in high estimation.

No. 2. Young Strawberry, was also bred by Mr. John Maynard. She was out of Old Favourite, and got by a shorthorned bull, bred by Mr. John Charge, of Newton, who sold him to Messrs. John Maynard and Duke Wetherill. This bull went by the name of the Dalton Bull, and was esteemed a first-rate bull at that time. Young Strawberry was of a beautiful roan colour. In the year 1785, when Mr. Charles Collings first turned his attention to the improvement of the shorthorned breed of cattle, he was desirous to procure the best cows and bulls, and such as had the greatest propensity to fatten. Old Favourite, and her daughter Young Strawberry, particularly attracted his notice, and he was desirous to purchase them. He had some difficulty in prevailing upon Mr. John Maynard to sell them, but he at length succeeded, and they became his property.

No. 1. Hubback, when four years old, was purchased by Mr. Robert Collings, of Barmpton, and Mr. Waistell, of Alichill, for the purpose of serving their feeding cows. He had such an uncommon inclination to fatten as to excite the particular attention of Mr. Charles Collings, who purchased him of Mr. Robert Collings and Mr. Waistell, about the year 1785. The judicious selection of Hubback, and of Mr. Maynard's two cows, as before mentioned, may be called the origin of the celebrated stock of Ketton Shorthorns, which for early maturity, inclination to fatten, and to acquire the greatest weight with the least offal, are unequalled by any breed of cattle in the world.

The bull Hubback was descended from the stock of Sir James Pennyman, Bart., of Ormsby, in Cleveland, Yorkshire, who, about the year 1770, paid much attention to the improvement of the shorthorned cattle, and purchased the best bulls and cows which he could procure. He purchased several cows of Sir W. St. Quintin, of Scampton, who was then celebrated for his breed of shorthorned cattle. It is probable that Hubback may have been descended from their breed, but the fact cannot be ascertained. Hubback was of a red and white colour, the red inclined to yellow.

No. 2. Foljambe, was out of a cow by Hubback, and was got by a bull belonging to Mr. Richard Baker, of Oxney Field, near Darlington, then in estimation as one of the best bulls of that time.

Of these extracts the following corrections or explanations suggest themselves;

The name of the owner of the sire of Favourite's grandam was Mr. Jolly, of Worsall; not Mr. Polly, of Worrall. The Dalton bull, better known as Dalton Duke, was bred at Dalton by Mr. Charge.

The received version of Hubback's pedigree is, that he was out of a cow belonging to Mr. Snowdon, of Hurworth, in the county of Durham, given to him by his

landlord, Sir James Pennyman, of Ormsby Hall, in Cleveland, which Sir James had obtained from Sir Wm. St. Quintin, of Scampston, in the East-Riding of Yorkshire; that he was got by a bull belonging to Snowdon; that Snowdon's bull was by William Robson's bull, Robson's bull being by William Masterman's bull, and Masterman's bull being by the Studley bull. As Hubback appears to have been calved in 1777, and is said by Mr. Youatt, in his work on cattle, to have served cows but a short time owing to his propensity to fatten, there seems an inaccuracy in saying that Mr. C. Colling, when he was *beginning* as a breeder, bought the bull at *four years old*, both these dates being assigned to 1785.

The following somewhat amusing account of the purchase of Hubback by Messrs. R. Colling and Waistell is given by Mr. Youatt in the work already alluded to.

Mr. Waistell (from whom Mr. Youatt had this information, in October, 1832) used to admire this calf (Young Hubback) as he rode almost daily by the meadow in which it grazed, and at length he attempted to purchase it from the owner. The price asked, £8, seemed much for a calf not a year old; and the reputation of the shorthorns not being yet established, the bargain was not struck. Still he longed for the young beast; and happening to meet Mr. R. Colling near the place, he asked his opinion of the animal. Mr. Colling acknowledged that there were some good points about him; but there was something in his manner of acknowledging this which induced Mr. Waistell to think that Mr. Colling thought somewhat more highly of the calf than his language expressed, and therefore he hastened the next morning to conclude the bargain, and paid the money. He had scarcely done so, before Mr. Colling arrived for the same purpose; and as the farmers rode home together, they agreed that it should be a joint speculation. Some months passed by, and either Mr. Waistell's admiration of the calf a little cooled, or his partner did not express himself very warmly about the excellencies of the animal, and Messrs. Waistell and R. Colling transferred Young Hubback to Mr. C. Colling, who, with the quick eye of an experienced breeder, saw the value of the little beast.

Foljambe was got by Mr. Richard Barker's bull, of Oxenfield; not Mr. Baker, of Oxneyfield.

Shortly after the Durham shorthorns had acquired the name of "improved" Durham shorthorns, a vehement controversy arose as to the origin of these same improved shorthorns; or rather, as the Collings had been the chief improvers, what the system was they had pursued in their improvements, or what, in short, they had bred from.

On the one hand it was maintained that this system had been that alleged by the writer in the *Economist*—"Careful selection from the local breed of shorthorns, which had already attained considerable perfection," in doing which they skilfully perpetuated excellences and obliterated defects. On the other, that it had been one of crossing in the extreme sense of the term, namely, the commixing of the bloods of totally different breeds of cattle.

The maintainers of the latter position were two-fold, who arrived from it at totally different conclusions. The first of them, being owners of Herefords and other rival breeds, asserted it to be a law of nature, that by crossing from animals of distinct breeds, no third or improved one could be obtained having the power of perpetuating itself; that the progeny always and shortly reverted to one or other side of the parentage; and that the improved shorthorns, having been produced by this kind of crossing, would speedily come to an end and totally disappear.

Upwards of fifty years have, however, elapsed; and the improved Durham shorthorns still hold their own, still continue to propagate their kind, their offspring showing no departure from the long-established type and character of their ancestry; and either, therefore, the theory of these objectors as to the effect of crossing was erroneous, their arguments fallacious, or they were in error as to the facts, the latter being undoubtedly our opinion.

The other class of supporters of the doctrine of extreme crossing were parties who, being owners of stock having in it the Galloway cross or "alloy," contended that this crossing was the system on which the Collings had proceeded universally, and that it was, in truth, the right mode of improving.

It may be here not unnaturally asked, how came it to pass that this subject had become a matter of conjecture and of controversy? Was nothing known as to the system the Collings had pursued? What were the facts? The brothers Colling appear to have been retired, reserved men, little thinking that their cattle-breeding proceedings were to become matter of public curiosity, or were to provoke controversy. They kept no record of their proceedings while they were in operation, nor did they leave any at the last; and seeing, as we have said, that the interests, or supposed interests, of various parties conspired to make it expedient to mystify the facts, it is not surprising that they were so mystified to a great extent. Now, however, that this mystification is passing away, the facts are, in our opinion, abundantly obvious. There had existed time out of mind, on both sides of the river Tees, from Barnard Castle downwards to Yarm, a peculiar breed of cattle—the Teeswater or old-fashioned Durham shorthorns. And long before the names of the Messrs. Colling had been heard, those of the following breeders and improvers of them had obtained celebrity, namely, Milbank, Brown, Hill, Wright, Charge, Maynard, Jolly, Hutchinson, Sharter, and others. And long before Ketton or Barmpton were known as shorthorn localities, the following places were in repute, namely, Barningham, Aldborough, Barton, Cleasby, Manfield, Stapleton, Dalton, Newton, Morrell, Blackwell, Oxenfield, Hurworth, Eryholme, Worsel, Sockburn, &c. This being so, where was it likely the Collings (living in this immediate neighbourhood), when they had determined on becoming breeders, went for their originals, but in the direction where a breed had long been in esteem, and where they had ample materials from which to make their selections?

In reference to this, Mr. Hutchinson, the author of the curious little history of the Sockburn shorthorns, written nearly forty years ago, says, "The editor of the *Farmers' Journal*, some time ago, asked whether the improved shorthorns originated in select individuals, or were obtained first by a cross? To which let me here answer, From individuals (I can hardly say *select* as regards Mr. C. Colling's stock) picked up by that gentleman at his own back-door, without trouble or expense: and no doubt he took the best he could come at." Knowing, as we do, the skill and tact of these gentlemen, we may feel assured that whatever this author may say of the absence of trouble or expense, what they "took" in this way—"the best they could come at"—were by no means despicable animals. Indeed, he says, as an instance of their judgment in such matters, that at the time they succeeded in buying "Old Favourite" and "Young Strawberry" of Mr. Maynard, they tried to buy one of the Sockburn shorthorns bred by his great uncle, Mr. J. Hutchinson, but could not succeed.

But though it may be fairly assumed that generally they did go to their own back-doors—into their own immediate neighbourhood—to get what they wanted in

the way of native shorthorns, and the great majority of their pedigrees conclude with a dam by Hubback, without giving any pedigree to her dam, yet we have not a few memorable instances of the pedigrees of their stock going beyond this.

Assuming, then, that Durham shorthorns are an indigenous race, established time out of mind in the localities mentioned, of which further evidence will be adduced, we have in the old-fashioned animal really a pure-bred animal. And if, as often occurs at sales of professed improved shorthorns, the pedigrees do not go back more than four or five descents, a purchaser may feel safe as far as purity goes. I by no means, however, recommend such pedigrees to persons beginning breeding in earnest, but that, like the Collings, they should get "the very best they can come at." And with a little diligence they may obtain stock descended in a right line through females from the best animals the Collings possessed, as well as others descended in the same way from the stocks of those who, as we have seen, were even their predecessors, namely, the Milbanks, Hutchinsons, and others.

With a view to aiding them in their search, I shall mention several extant descendants in a right line through females of some of the Collings' best known cows, and also descendants of the same description from the stocks of the other parties we have alluded to. I take, in the first place, the descendants of those of the Collings' cows, whose pedigrees go even beyond Hubback, namely—1, Favourite; 2, Princess; 3, Duchess; and 4, Fortune. And, first, with regard to the descendants of Favourite or Lady Maynard, who may indisputably be taken as "No. 1" when treating of shorthorn pedigree. Favourite had of daughters, Young Strawberry, Miss Lax, and Phœnix. Young Strawberry was by Foljambe, the dam of "Lord Bolingbroke," who was sire, by the O'Callaghan Galloway, of the bull "Son of Bolingbroke," who by "Old Johanna" was the sire of "Grandson of Bolingbroke," wherein we see the origin of the Galloway cross or "alloy," hereafter to be discussed. Phœnix having had by Bolingbroke the celebrated bull Favourite, had also by "Grandson of Bolingbroke" the cow Lady, from whom chiefly are descended the branch of shorthorns having "the alloy." Phœnix also had, by her own son Favourite, Young Phœnix, who by the same Favourite had the renowned "Comet," the first, and for many years the only bull sold for one thousand guineas. Of these two daughters of Favourite, viz, Young Strawberry and Phœnix, I am not aware of there being any right line descendant through females; and so proceed therefore to her other daughter Miss Lax, who was, as well as Young Strawberry, by Dalton Duke. From her descended, through females, No. 4 at the Chilton sale, and through her many other animals at the same sale, several of which went to Ireland. Lord Spencer, then Lord Althorp, bought Nos. 13 and 55, esteemed amongst the best. They were both daughters, as we have seen, of No. 4.—No. 13 being by St. Albans of the "Princess" family, and No. 55 by Monarch of the "Favourite" family.

During Lord Spencer's life, female descendants of these cows were rarely if ever to be obtained. But by the three sales of his stock at Wiseton they were dispersed. The No. 13 line, belonging to Lord Spencer, seemed at one time to have concentrated in Roguery by Mercury who was a grand-daughter of No. 13. She, however, was very prolific, and had of cows, Zeal, Zinc, and Zone, and of bulls Zadig, Zenith, and Zoroaster. Zeal, a very fine cow, bought at the first Wiseton sale by Mr. Wilkinson, of Lenton, had many descendants, both while belonging to that gentleman, and previously when belonging to Lord Spencer—Prophetess, Prudence, Wiseton Lady, &c. The same, as to descendants, was the case with Zinc, who had Teturia, Metal, &c. It appears that it is through Zeal and Zinc that there are descendants of No. 13 to be offered at the sale you allude to.

No. 55 had also many descendants who were brought into the market at the Wiseton sales. Of these, Enigma was purchased by Mr. Topham, and Florentia by Lord Ducie. From Enigma and Florentia there appears to be, at the same sale, descendants of No. 55.

The Princess Family.—The pedigrees given of Princess are not only various, but conflicting. At the sale of Sir H. V. Tempest's herd in 1813, she is said to have been by Favourite, her dam by Favourite. The same pedigree is given in the 1st volume of the Herd Book published in 1822. The 3rd volume of the same book, published in 1836, gives her pedigree, as being by Favourite, dam by Favourite, g. d. by Hubback, gr. g. d. by Snowdon's bull, — by Waistell's bull, — by Masterman's bull, — by the Studley bull. This is to be found in the pedigree of her grandson St. Albans (1412). Again, where the pedigree of the bull Belvedere (1706) is given in the same volume of the Herd Book, she is said to have been by Favourite, dam by Favourite, g. d. by Hubback, gr. g. d. by Snowdon's bull, — by Masterman's bull, — by Harrison's bull, — bought by Mr. Hall, of Sedgefield, of Mr. Pickering. Princess was, as we have always heard, an extraordinarily fine cow, and the late Sir H. V. Tempest, of Wynyard, in the county of Durham, who was an admirable judge of the points and excellences of the whole animal kingdom, from a race-horse or short-horn down to a game cock, resolved, it seems, on being her owner at any price. It was never known what he gave Mr. R. Colling for her, secrecy on that head appearing to have been part of the bargain; but it has been said to have been as much as 700 guineas. Princess and her numerous descendants were sold in 1813, after Sir Henry's death. The late Mr. J. Wood, of Kimblesworth, bought one of her daughters, Nell Gwynne, then in-calf to Wynyard, and she afterwards produced St. Albans. We believe the pedigree of St. Alban's, and consequently of Princess above alluded to, to have been furnished by that gentleman, and we are sure, from our thorough knowledge of him, with the most perfect good faith. We cannot but suspect, however, that an error has crept into it, from a confusion of the pedigrees of sires with those of dams—Waistell's bull having been by Masterman's bull, Masterman's bull by the Studley bull. At this sale Angelina, the daughter of Anna Boleyn, another daughter of Princess, was reserved; and at a subsequent sale a daughter of Angelina was bought by Mr. J. Stephenson, of White House, Wolviston, a neighbouring tenant farmer. From her descended Belvedere, who became the property of Mr. T. Bates, by whom, we believe, the pedigree of Belvedere, and consequently of Princess, was furnished. We have heard Mr. Bates say, speaking of the pedigree of Princess, that such it certainly was, because her dam was own sister to Mr. R. Colling's white bull. Yet, according to the pedigree of that bull, given in the Herd Book, he would have been own brother to Princess. Who shall decide when such doctors disagree? We feel, however, justified in assuming that Princess belonged to the class of those descended of cows belonging to the Collings', which had a pedigree before they obtained them, whether her first-recorded ancestress was "bought by Mr. Pickering of Mr. Hall, of Sedgefield," or was by "the Studley bull." Of whom they obtained her, it is not we believe known. Nell Gwynne, Mr. J. Wood's purchase, became, as we have said, the mother of the well-known St. Albans; and Mr. Mason, of Chilton, having obtained of him St. Albans' services for some time, he became thus, as we have seen, the sire of No. 13 at the Chilton sale, the ancestress of Lord

Spencer's Old Roguery, and her numerous progeny of Z.'s. Nell Gwynne had but one heifer-calf having descendants: this was by Layton (366). Mr. Wood sold it to Mr. Troutbeck, of Blencoe, in Cumberland, who had been his pupil. By Mr. Troutbeck this heifer was christened 2nd Nell Gwynne. Of Nell Gwynne the 2nd many descendants in a right line of females have of late years appeared in the market, and not a few have attained show-yard honours. At one time, however, a notion existed that Mr. Troutbeck had not been very select in the choice of some of his bulls.

From Angelina, the granddaughter of Princess, descended Belvedere, obtained, as we have seen, by Mr. Bates, from Mr. J. Stephenson, and to this cross with his Duchesses Mr. Bates always attributed the greatest advantages. Those who knew his worth knew also his strong prejudices, one of which was against the "alloy;" and a strong suspicion exists that Lawnsleeves ought to have had a place in the pedigree of Belvedere; but a belief having existed that, according to the Herd Book pedigree, Lawnsleeves had the alloy in it, he was accidentally omitted. Some years ago the writer, when on a visit at Elmore, the well-known residence of the late George Baker, Esq., the owner of Lawnsleeves, discovered, on reference to dates, that Lawnsleeves' dam could not have been the daughter of the "alloy" George, but probably by Mr. Mason's George, who was much nearer at hand, that gentleman, moreover, being well known to Mr. Baker. Had this been but sooner known, the discussion *need* not have *occurred*.

Mr. J. Stephenson still has right-line descendants through females of Angelina, though he is not easily persuaded to part with them.

Those which we have mentioned were considered for many years the only right line female descendants of Princess, but recently a new family has appeared from Northamptonshire, claiming so to be, as to which we are not prepared to speak authoritatively in the negative.

THE DUCHESS FAMILY.—Mr Bates's Duchesses, they may be called, being all of them, at one time, in his possession, and being all christened by him Duchess, with a numerical distinction. They descend from the cow Duchess, bought by him at Mr. Charles Colling's sale, in 1808, and whose pedigree was then given as being by Comet, dam by Favourite, g. d. by Daisy bull, gr. g. d. by Favourite, — by Hubback, — by James Brown's red bull. We are not aware whether the cow by Mr. J. Brown's red bull was purchased or bred by him. Assuming the former to be the case, which we believe, she belongs to the class of cows having pedigree when he bought her, though of whom he did so we are also ignorant. It is generally understood that the Duchesses were not going the right way, when Mr. Bates bethought him of introducing the Princess cross through Belvedere. Hearing of his existence, and of his being the property of Mr. J. Stephenson, he went to Whitehouse to have a look at him, and, as we have heard him say, the door of Belvedere's house being locked in the absence of Mr. J. Stephenson from home, he had his first inspection of him through a hole in the wall, and the bull appearing just what he wanted, he too seemed to have exclaimed Eureka! eureka! Having ultimately succeeded, as we have said, in obtaining him from Mr. J. Stephenson, from thence dated the fame of the Duchesses. Since Mr. Bates's death they have passed into many hands.

THE FORTUNE FAMILY. — The first recorded ancestress of this family was obtained by the Collings, from Mr. Maynard, as were Old Favourite and Young Strawberry. The pedigree of Fortune is, that she was by Bolingbroke, her dam by Foljambe, g.d. by Hubback, gr. g. d. bred by Maynard. She was the dam of many celebrated animals, both male and female, namely B (45), Irishman (329), Cripple (171), Trunnell (659), St. John (572), Gaudy (p. 320), and Nell (p. 422). B (45) was the ancestor of Portia (No. 2 at the Chilton sale) who was the dam of Lady Sarah (No. 20), the highest priced cow at that sale. No. 4 at the same sale was a right line female descendant of Nell, and Nos. 35 and 51 were daughters of No. 4. There are still right line female descendants of Nell, and we owe it to that most distinguished breeder in another department, Mr. Jonas Webb, to mention his name as being a possessor of such descendants.

THE DAISY FAMILY. — Of the Collings' cows from whom right line female descendants are existing to this day, but which cows have no pedigree assigned them previously to their being in the Collings' possession, we believe there are but few. There is one, however, well-ascertained family, which must not be omitted, namely, that of Mr. C. Colling's "Old Daisy." Her pedigree is — got by Favourite, her dam by Punch, g. d. by Hubback. She was own sister to the "Daisy bull," of whom Mr. Bates always made especial mention when recounting the pedigree of his Duchesses, the Daisy bull being one of their, in his opinion, most-valued ancestors. Of the right line female descendants through females of Old Daisy, we remember to have seen two or three at Mr. Jefferson's sale, at Fulford, near York, last summer, which brought high prices, and there are some, we see, at one of the sales this month—that of the 21st.

Of the right line descendants, through females, of cows belonging to breeders of shorthorns antecedent to the Collings, now existing, we have an instance in what may be termed

THE MILBANK FAMILY.—The Milbanks, of Barningham, were amongst the very oldest recorded breeders of shorthorns. One of their cows appears to have come into the possession of Mr. Coates, and was by him named "Milbank," from which there are existing right line descendants through females at this day. At two of the sales you allude to members of this family are to be disposed of.

THE SOCKBURN FAMILY. — Another family of this description is "the Sockburns," originally belonging to the Messrs. Hutchinson, of Sockburn, one of whom, as we have said, wrote a history of them. Either while in their possession, or as we believe subsequently, the last of the Sockburns having right line descendants through females was put to Major (397), a son of Lady, imbibing thus the "alloy." Notwithstanding his antipathy to the "alloy," Mr. Bates became the owner of one of her thus alloyed descendants—a strong proof of its merits; and from her he bred, using Belvedere, and again one of his Dukes. From this cross have descended animals of first-rate character at this day, one or more having been purchased by Colonel Towneley, and have distinguished themselves in the show-yard.

It must not be thought that in having confined myself to the pedigrees of those families of shorthorns which can establish right line descent through *females* from cows having pedigrees at the time the Collings purchased them, and from cows belonging to their predecessors as breeders, I in the least undervalue those pedigrees which are computed merely from sires. It was to establish and illustrate my argument, *that Durham shorthorns of celebrity were in existence before the Collings began their career as breeders, and that there are at this day right line descendants through females of the principal cows they bred from, and*

from cows belonging to their predecessors, that I adopted this course.

Though shorthorn breeders compute the pedigrees of their cattle, as do the Arabs their horses, by their dams, either animals are in fact as much descended from the dams of their sires as from the dams of their dams; and thus in the pedigrees of shorthorns, containing such names as Foljambe, Bolingbroke, Favourite, Comet, &c., those to whom such pedigrees belong are in fact equally descended from Old Favourite, Young Strawberry, Miss Lax, &c., as those which trace their descent from cow to cow.

I proceed now to address myself, as I promised, to the subject of "the alloy." It originated, as we have seen, from what has been unceremoniously called O'Callaghan's polled galloway. Now, this same O'Callaghan was Colonel James O'Callaghan, of the noble house of Lismore, and a great friend of the late Duke of Cleveland, one of whose boroughs he represented for many years in the House of Commons. The Duke, as Lord Lieutenant, also made him Colonel of the Durham militia. Having pitched his tent, in the decline of life, at Heighington in that county, he there ended his days, as he had lived, a very popular character. Having bought a couple of polled galloway cows, he had no difficulty in getting Mr. C. Colling, his near neighbour, to allow him to send one of them to his bull Bolingbroke. She produced a bull calf. It was a roan, in due time had *horns*, and showed all the other indicia of a true-bred shorthorn. Such was "Son of Bolingbroke." Mr. C. Colling bought him and his dam of Colonel O'Callaghan, and put his cow, old Johanna, to this son of Bolingbroke. She produced a red and white bull calf, who, like his father, took in all respects after the Shorthorns. He was yclept "Grandson of Bolingbroke (280)." To him Mr. C. Colling put Phœnix, daughter, as we have seen, of "Old Favourite," and she produced "Lady," as she had before done, by Bolingbroke, the bull "Favourite," the father of Comet; and also (by her own son, Favourite) Young Phœnix, the mother of Comet. Lady was the dam of Washington (674), Major (397), George (276), and Mr. Wright's Sir Charles (592), and also of Countess and Laura. At Mr. C. Colling's sale, in 1810, this alloy stock sold at very high prices—Major for 200 guineas, George for 130 guineas, Lady herself, at 14 years old, for 206 guineas; Laura, her daughter, for 210 guineas; Laura's daughter, Young Laura, at 2 years old, for 101 guineas; and Countess, the other daughter of Lady, was *bought of Major Rudd, of Marton, for 400 guineas*. When we meet, therefore, with descendants of "Grandson of Bolingbroke," or of Major, George, or Sir Charles, such as "Western Comet" (689), Frederick (267), Keswick (453 and 1266), or of Countess or Laura, we encounter the alloy. But what do we therein encounter that is base or injurious? What is the meaning of alloy? Here we have a cross with a breed of cattle of first-rate character and quality, and polled Galloway breeders might equally say they had been alloyed by the Shorthorn cross We are satisfied, however, that in fact "the alloy" never took—that it was utterly and speedily thrown out—and that, as did the son of the polled Galloway by Bolingbroke, so did all his descendants adhere to the Shorthorn side of the house. I have never heard that any of them were without horns, or exhibited the least trait of the polled Galloway, except, it may be, in the analogous good qualities of that breed. I incline to think there is truth in the theory that, in crossing distinct breeds, the offspring does take exclusively at once, or very shortly, to one or other side of the house.

We appear then to have, in the instance of the alloy, an illustration of M. Malingié Nouël's ingenious theory of the difficulty of changing the type or characteristics of a long-established breed, and that this difficulty is in proportion to its purity of blood, or, in other words, to its antiquity.*

If this be true, the non-infection of Shorthorns by the alloy affords an additional argument in favour of the ancient and indigenous character of the breed. But had the first offspring of this cross partaken equally of the bloods of its different parents, in what proportion would the Galloway blood exist in any modern Shorthorn? Seeing how early capability of procreation exists, and is called into operation in that breed, and also how rapidly generations of cattle pass away, I do not believe there is an extant Shorthorn which has an appreciable particle of the Galloway blood in its veins. I must say I think this kind of crossing, or, perhaps, rather attempted crossing, a mistake—a mere waste of time.

Take the case, well-known to greyhound coursers, of Mr. Goodlake's bull-dog cross. Considering the position the dogs thus "alloyed" hold as to their "public performance," does any one think this cross has been injurious, or can any one from their appearance discern it? Yet we think it was a mistake.

Being of opinion, then, that the alloy has done neither good nor harm *directly*, I am not so sure that indirectly it may not have done good. Those who had it in their stock became less scrupulous on the score of pedigree, and, unlike pedigree martinets, looked less to that than to the good qualities of a bull. It may be thus, perhaps, explained how it has come to pass that many animals having in them this once dreaded bugbear, the alloy, have taken the highest places in the show-yard. I do not allude more particularly to these animals, lest I should revive against them this stupid prejudice of "the alloy," and a more stupid prejudice, a more complete phantom cannot exist. Breeders, however, will understand my allusion. We maintain it then to have been established by this narration *that the Collings in general, notwithstanding what Mr. Chas. Colling did in a particular instance, formed the improved shorthorns by careful selection from the local breed, which had already attained considerable perfection.* That such is the antiquity and indigenous character of the old-fashioned shorthorns, such its native purity, that even should any commixture of ingredients of another kind have taken place, yet like an infusion of the same sort with the waters of father Tees, it has been speedily thrown off without affecting its perennial purity.

The owners of our native shorthorns, therefore, may snap their fingers at the ancient myths, as to "wild cattle from Chillingham-park," and "Dutch or Holstein cattle from across the German Ocean." Those who have seen the wild cattle at Chillingham, will bear me out in saying, there is not a single characteristic or point of resemblance exhibited by them which is possessed by the shorthorns, except that shorthorns are occasionally *white*, but they are also sometimes *red*, yet no one has ever ventured on that score to point to the Devon or Sussex breeds as their original. As to the Dutch or Holstein importation, of which one used to hear so much, the writer happened some years ago to stumble on a fact, tending to turn the tables on the Holsteiners. It seems, according to Anderson (in his treatise on Commerce), who quotes from Rymer's *Federa*, that Edward IV. allowed a favourite sister, Margaret, Duchess Dowager of Holstein, to export from this country annually, and for many years into Holstein and the low countries, great numbers of cattle and sheep, for the purpose of improving the breeds of them in those countries. Whence is it so likely they were exported, as

* See Vol. xiv., p. 214, of the Agricultural Society's *Journal*.

from the ports of Hull and Newcastle across the German Ocean? And if it be true, as has been said, that some centuries after, a herd of cattle was found there greatly resembling our native shorthorns, whence may it not fairly be assumed the originals came? And when, as it is said—for it rests only on tradition—some of these were brought into this country, what was this but a re-importation, what was it but that England had her own again? I remain, Yours, &c.,

DUNELMENSIS.

THE PRESENT POSITION OF THE FARMER.

The farmer is proverbially prosperous. He has a conventional character to maintain for being well-to-do, that has stuck to him ever since "the war." Just as the Jack Tar is jolly, the lawyer learned, and the soldier gallant, is he to be associated with the making of money. No matter how much he may complain at times, the world always knows bettter. Whatever difficulties he has to encounter, we think only of what wheat was fetching a few years ago. Tradition has told us how, in eighteen hundred and something, a Hampshire man drove into his market ordinary with a pair of horses to his phaeton, and we never lose sight of them. In a word, we are always ready to take the farmer's position at a premium. When he is doing well we make the most of it, and when he is doing badly we say nothing about it.

There are few, not directly interested in the pursuit, who would care to think it was just now somewhat hard times with farmers. On the contrary, the public remember nothing but the high prices of a year or two since. Indeed, to their credit be it said, the tenantry themselves have not forgotten them. The turn they had still enables them to hold on. Let there come a commercial crisis, and people yield at once to the pressure. It is only in the common course of things that Houses should "go" right and left, notwithstanding what they may have profited by previous speculations. All our sympathies are with them. We see and feel what they have had to contend against, and commiserate with them accordingly. But the mere cultivators of the land come in for no such consideration. We only bear in mind how dear bread was, and how much they ought to have saved. And then, again, the weather has been so much in their favour; another point we are always ready to make the most of. "Fine weather for *you* farmers," said a cockney tourist to a friend of ours he met in one of his own fields lastautumn. "And not very bad for *you* excursionists," was the apt rejoinder. People are always patronizing his prosperity.

But there is occasionally something far worse in this making the most of it. Landlords, and land-agents especially, are by no means loath to look always on the sunny side. We hear, even very recently, of rises in rent, consequent on the visitation of an experienced valuer. A correspondent recently referred to several landlords who last year gave their tenants notice to quit in order to raise their rents, "the comparatively high prices of the year or two previous having made them uneasy." The question is whether the present low rates will make them feel more easy again? Or, will it be the old story of the boot-maker and his customer—"Well," said the latter, "now they have taken the tax off leather I suppose I shall get shod a little cheaper?" "No, sir," was the answer, "I was just about to raise the price when they did it, so we shall go on as before." Some landlords, perhaps, who were about to raise the price will now go on as before; but at most they must be content with this.

After all, what is it the farmer has to fall back upon? Have the opportunities of the last few years been really so great as the world at large would appear to imagine? The authority we have already referred to runs on thus: "Let us consider what these high prices have been. Wheat has been higher than other grain, the crop of barley of '56 alone excepted. Now, will the average of wheat for the last 10 years exceed 50s. per quarter? if not, there certainly can be no reason for a rise on that score. The fact is, wheat was very dear in 1854-55, from the very deficient harvest of '53, which of course is no benefit to the farmer, to receive a high price for a short crop. I heard of good wheat land that year growing only 3 sacks, that usually grows 9 per acre. Landlords should recollect that high prices, in such cases, are not so beneficial to the farmer as good crops and lower ones." A short crop of wheat, then, does not tell like a bad hop year, although some people really argue as if it did. Even keeping to this question of price, let us see how much the balance of the good times has actually been in favour of the producer. Let us date it from that golden age which came in with Free Trade. In our last week's summary of the business done, it is thus written: "In reviewing prices since the last Corn Bill came into existence, we find the average price for the whole eleven years amounts to 55s. 10d, the extremes being 39s. 5d. per qr. in 1851, and 73s. 1d. in 1856. As the last weekly averages were 44s. 3d., we are 11s. 7d. per qr. below this 11 years' average. Now as only one year and a quarter has elapsed since the highest range, the fall in such a course of time is greater than has occurred before in this short period." We shall be bold to say that, if such a change had occurred in the commercial instead of the agricultural world, we should have heard a vast deal more of its effects. As it is, we must not neglect the signs of the times.

Amongst the most valuable intelligence, we certainly regard the monthly County Reports. We are justified in announcing them as supplied by the best men of their several districts. They appear, moreover, invariably in that form in which they are forwarded. No attempt is ever made to dove-tail the opinions in one with that of another. They are, in fact, the independent testimony of men fully qualified to speak on the subject matter of their communications; and it may be well worth our while to see what their latest advices offer on the state of the case. Let us take them as they come, and begin with LINCOLNSHIRE: "As to our own supplies, hundreds thrashed their all immediately after harvest, and it is gone. Beef, mutton, pork, and wool are all lower in price; the latter not much in request. It is customary to compare the early spring stock markets. We find upon the average the difference in price as compared with the two preceding years, in cattle and sheep, is about thirty per cent. This is a great depreciation in the value of agricultural produce, and will ere long show itself in many distressing cases of individual suffering. We have seen so much of this class of trial and misfortune as to make us tremble for one's friends and neighbours, each of whom having suffered a loss of one-third of their property in a few short months."

NORTHUMBERLAND endorses these fears with yet more startling facts:—"The monetary crisis that

collapsed on the commercial interests of the country in November has not failed to recoil on food-producers, and wherever rash speculation or the most rigid economy has not been observed, sequestration of effects have since Christmas taken place over this once-flourishing locality to an extent unprecedented, we believe, since the first ten years of the present century: confidence is shaken to the core, and every business transaction worked out 'from hand to mouth.' We have never disguised our opinion that the profit of the farm would be *nil*. Then we lived in hope of quiet reaction in trade: our markets, on the reverse, continue languid in the extreme; every return shows a downward tendency. Whenever reaction takes place, the million will, for a time at least, be dependent on foreign supplies of breadstuff. Granaried corn, we believe, is unusually scant; and looking at the corn in bulk, also considering defective yield from our last crop, the quantity to be realized from the stack is certainly less than usual at this period of the year. Nor can we say much in favour of the rising crop."

From CAMBRIDGESHIRE we have but another echo of the complaint: "The price of nearly all farm produce has gone down very much—indeed, too low for the well-being of the farmers, very good wheat selling at 5s. per bushel, the coarser sorts still lower; while the stock of the farm has greatly deteriorated in value, and the fattening of all animals has been this year a desperately losing game. There appears a very heavy cloud at present over-shadowing our agricultural prospects; and we take our mark amiss if those farmers who have lately taken their farms at an advanced rent do not find out their mistake. We have not an overweening disposition to look at the gloomy side of the picture, but there is no mistaking the fact that the loss of property by the British farmer within the last six or nine months (in one form or other) amounts to a most frightful sum."

From BERKSHIRE we have, more especially, intelligence on the present price of stock, all to the same end:—"The trade in beef is extremely depressed, more particularly for inferior descriptions; the general dulness of trade is also felt in mutton. Fat lambs are scarce, and great activity in the trade has prevailed during the last week. Porkers and bacon hogs meet a sluggish demand, at receding prices. Veal is also cheaper. The trade in store sheep is dull, and prices have given way from 2s. to 3s. per head. Prime cows just calved sell fairly, but all other descriptions of horned cattle share the general depression. Store pigs, particularly the larger ones, are difficult to sell. Good horses of all descriptions sell readily, at about 20 per cent. cheaper than last year; inferior sorts are neglected. There is scarcely anything doing in wool. Hay continues quite a drug. There is rather more inquiry for straw. Potatoes hold out well, and early sorts for planting have been in fair demand. The lambing season is now nearly over, and the increase is moderate; in some of the large flocks considerable mortality among the ewes has prevailed." WARWICKSHIRE confirms this:—"The fairs have been well supplied with fat stock, for which there is a slack demand." And DURHAM adds:—"Our fat cattle markets have been well supplied, and prices have had a downward tendency. Grazing has not been remunerative; of cattle that were bought-in in October and November, in many instances their keep has been given away."

In a yet more noted district—LEICESTERSHIRE—"The price of all kinds of stock has of late been declining, and is lower than this time last year; yet the market for beef and mutton being depressed, the grazier is very cautious of buying at present prices. Fat beef is selling at 5d. to 6½d., and mutton in the wool at 6d. to 7d. per lb." And, "Wheat has receded in value till it has reached a figure at which it is not remunerative to the grower."

YORKSHIRE declares: "Fat is plentiful, and bad to sell at anything like remunerative prices to those who purchased feeders in the autumn."

The climax comes appropriately in the concluding report of the whole number, that from SOUTH SHROPSHIRE: "The worst symptom at present is the gradual fall in the price of beef and pork; mutton is also lower, but not to the same extent. Instances are very numerous in this part of the country where cattle have been fed for five or six months, and sold out recently at less money than they were bought in: indeed, we have heard of instances where less than the cost-price has been accepted, even though the animals had been kept on the best food the farm produced. At our local fair at Ludlow, on Tuesday last, the top price of beef was 5½d. per lb., and a good deal changed hands at 5d., or a trifle over, several of the best lots returning home unsold. It must also be observed that the quality of the animals shown at the above-named town is first-rate, being almost entirely of the Hereford breed."

A reference to the recent reports of the meat market will show a still further decline. The trade never looked so bad as it does at this moment.

Shall we sum all this up? The average price of corn is lower than has been known for many years. Cattle and sheep never brought a worse return. Good manures are unprofitably high; and taxation quite as heavy as ever. Still the farmer has made the most of his opportunities. No one will deny but that within the last few years the art of agriculture has greatly progressed. All we ask for it is fair-play; more particularly from those most interested in its advance. Let us hear no more of "harsh cases." Let us have no more sharp practice in raising rents, simply because a bad man may be ready to outbid a good one. Let landlord and tenant pull together, and the Firm will pull through.

IMPORANT TRIAL.—VERDICT £1000.

SALE OF CATTLE AFFECTED WITH PLEURO-PNEUMONIA.—VERDICT FOR THE FULL VALUE OF THE CATTLE.

Kildare Spring Assizes.—Before the Lord Chief Justice of Ireland.

MALCOLMSON *v.* M'DONOUGH.

Mr. M'Donough, Q.C., stated the case for the plaintiff. It became his duty to state the various facts and circumstances from which he asked them to find a verdict of substantial damages. The action was one of considerable importance to the parties concerned, and the public in general. It was particularly important, as the defendant would seek to involve the case in some difficulty, arising from matters, not of fact, but of opinion. No question was raised as to the existence of the warranty. It was a fact which the defendant could not deny. If a single heifer were diseased, the party could bring

an action, and recover damages for it; but in the present case the plaintiff sought large damages for the infliction of a great wrong. The defendant should show that the cattle were all sound, as warranted. The plaintiff would prove that they were not sound; and the case would eventuate in an inquiry as to the amount of damages. The plaintiff resided in the county Carlow; he held several grass farms in the county Kildare. He possessed 1,500 acres of feeding land. The defendant, Mr. Walter M'Donough, lived near Ballinasloe, county Galway. He was one of the most extensive stock farmers in the county. He held vast tracts of land in Galway, Roscommon, Mayo, and the King's County. In a great degree he confined himself to the rearing of stock. Upon the 4th of October the fair of Ballinasloe began. Upon the 2nd of October, 1857, the plaintiff was at the fair of Moate, and purchased from a Mr. Hudson ten large bullocks. Upon the 8th of October, the day of the sale of black cattle at Ballinasloe, he purchased the heifers of the defendant. It was desirable to purchase cattle from one person whose respectability was a guarantee for the soundness of the animals which he sold. The defendant had his cattle separate and apart from others, under the great wall of Lord Clancarty's demesne, in lots of 30 each. The plaintiff had previously suffered in consequence of having purchased unsound cattle, and on this occasion he adopted the wise and prudent course of making particular inquiries of the vendors, and in every instance insisting upon engagements. Accordingly, he proceeded to the lots of the defendant and made particular inquiries whether they were sound. He was informed that he might rest satisfied, as he (defendant) had reared every one of them from calves, and he had not a single case of distemper or disease amongst his various lands for the last two or three years. He was asked for an engagement, and he undertook and did give an undoubted warranty. The plaintiff purchased two of the lots, No. 7 and No. 8, each consisting of 30 heifers, at £12 15s. per head. With these lots he did not find fault, because he considered that the disease was confined to lot No. 11. The plaintiff was afterwards solicited to inspect lots Nos. 10 and 11. The defendant pledged himself to their quality; as he said every one of them had been reared by himself, he (plaintiff) need not be afraid, as he would engage every one of them, and if he would consent to take the cattle he might pay him in any way he thought proper. The plaintiff was, accordingly, induced to buy lot No. 10 at the rate of £12 15s. per head, and to purchase eventually the remaining lot, No. 11. He likewise purchased ten bullocks from Lord Ashtown. These heifers were brought to Carlow; they stopped at intervals along the road, and were taken care of by a trustworthy servant. Upon the 12th October they stopped at Mr. Johnson's, of Miltown, near Athy, where they were permitted to remain for the night. Mr. Johnson observed that two of the heifers laboured under the disease; one of them being considerably worse than the other, and he considered that the lot was distempered. The cattle were removed to a farm of the plaintiff's, which was situate a few miles from Carlow (Garryhindon). The plaintiff saw the cattle in the morning, and he perceived that one of them was distempered. He separated the diseased beast from the rest. She was so bad that he sent her to Smithfield at once; and instead of selling her, they were at once obliged to slaughter her. In a few days another heifer in lot No. 11 exhibited symptoms of distemper: 170 beasts in all became infected with and displayed symptoms of this latent infirmity and disease. It appeared that the disease, which first exhibited itself upon the continent, was in the year 1842 or 1843 introduced into Ireland. A post-mortem examination of the animal plainly demonstrated that it was a disease which grew upon it day after day. The affection was this—the lungs adhered to the side, fastened, as it were, by ligatures; it was difficult to tear the lung from the side, and became necessary, in fact, to tear them asunder. The period of development ranged from three to six weeks, and this fact coincided remarkably with the present case. The learned counsel then read several letters which passed between the plaintiff and the defendant. In reply to a communication from the plaintiff to the defendant, written on the 20th of October, 1857, he (defendant) stated "that he had no sickness amongst his cattle for two or three years; that lot No. 11 were not fed upon the same farm as the others had been; that the latter, which he had since, were yearlings, and had been fed in Roscommon, where no sickness had been for three years; that lot No. 11 had been bought last April with others which had been sold only in September to the butchers at Ballinasloe, and that there had not been any complaint from any quarter in reference to them. The plaintiff examined more closely lot No. 11, and discovered that they could not have been reared by the defendant. Some of them had different brands, and some were not branded at all. This lot he separated from the others. He kept lot No. 11 at the farm to which they had first gone, and he scattered the rest among his other farms. The result, however, was that the infection spread. On the 1st of November, 1857, the plaintiff wrote to the defendant, stating that he was sorry at being obliged to inform him that he had four of the heifers of lot No. 11 very bad with the lung distemper—that there must have been some disease in that lot for a considerable time, although he (defendant) might not have been aware of the fact, and that he was preparing to send them by a float, as the railway company would not take sick cattle in their trucks. The defendant did not answer these or other letters. There was a complete examination of lot No. 11. A Mr. Shaughnessy acted on behalf of the defendant. The plaintiff said that there must have been some disease amongst the cattle. Shaughnessy was rather reserved in his manner, but he said he was certain the defendant could have warranted every lot from No. 1 to No. 10. It would seem that lot No. 11 was a mixed lot, which had been collected for the purpose of rapid sale. It was arranged that the cattle should be shipped to Liverpool, and disposed of there. A proposition was made to leave the matter to the arbitration of two respectable and experienced gentlemen; but this was not carried into effect. On the 27th of November, 1857, a letter was written by the plaintiff to Mr. Shaughnessy, telling him that he had been obliged to ship six of the heifers that day, and three of them on the previous day, in all eleven; and that "it was surely madness in the defendant not to give instructions to him in reference to what he desired to be done with the remainder, as the loss would and must eventually fall upon him" (defendant). On the 28th November, 1857, another letter was written by the plaintiff to the defendant, to which there was not any reply. Upon the 30th of November another letter followed, complaining that six more of the cattle were ill, and informing him that he should send them off that very night, requiring instructions as to what he should do with the cattle, and expressing his firm conviction that all of them would die. After this the plaintiff announced that three more of the beasts were sick of the distemper, and that prompt measures were required on the part of the defendant, otherwise they could not be rescued from the disease, and the loss consequent upon the distemper could not be averted.

The plaintiff deposed as follows:—He is an extensive grazier, holding about 1,500 acres of land, chiefly in Carlow and Kildare; he had known the defendant nearly three years; he was a large stock proprietor; on the 2nd of August he bought about ten bullocks from Mr. J. Hudson, at his place, near Athlone; these were afterwards sent home along with the cattle purchased from the defendant; the 8th of October was the black cattle fair day at Ballinasloe; the defendant had a particular stand by the boundary wall of the fair ground, in lots of thirty, so that they were completely separated from the rest of the cattle; the warranty given by the defendant was to this effect; he said, "By my honour, my dear fellow, I have not had a case of distemper or disease amongst my cattle for the last two years; I have had them almost from the time they were calves, and I can warrant every heifer which I have in the fair as sound," and putting his hand upon his shoulder, he said "Now buy a few lots from me;" witness purchased lots Nos. 7 and 8, for £12 15s. per head; required the cattle with the view of selling them in the following summer; after he had made this purchase from the defendant, he went through the fair and looked at several lots; he bought lot No. 10 at the same price; subsequently bought lot No. 11, and with these also the same warranty or engagement was given; sent lots of the cattle to his different farms, which were separate and far apart in the county of Carlow; the disease broke out amongst the cattle in every instance; the nearest farm to Dublin upon which he had the cattle, except one farm, was forty-four miles.

Cross-examined by Mr. Battersby, Q.C.—One of the heifers had slipped her shoulder, and she died upon the road; wrote to the defendant in reference to this, and he in a very handsome manner sent him a £5 note; he considered that it was a very handsome thing to do, as there was no warranty given, and the defendant was not bound to act as he had done; and this he would say, he very much regretted having had any

misunderstanding with the defendant; had several "strippers" on his land in August last; perhaps he had 50 or 60; had no old cows; could not tell how many hundred horned cattle he had on his land in that month; had several hundreds, about 250; had these from the previous October; his man had sold beasts to a butcher named George Hirley; had only two distempered cows on his land before the 1st of October, and these he disposed of at once; in the year 1847 he lost 125 head of cattle; could not tell where he bought these, but could swear positively that he had no distempered cow on his lands for nine months before the fair at Ballinasloe; about nine or ten years ago a man of his made an engagement about a horse he sold to a party, and he (Mr. Battersby) defended him; before he bought the cattle heard that there was a good deal of distemper in the fair; would not consider it safe to put sound cattle upon land where there had been distempered cattle before three months; thought there was great danger from the virus, the saliva, distempered mucous, and droppings from the mouths of diseased cattle remaining upon the land; the disease was not perceptible for one month to six weeks; detailed the symptoms exhibited in the first week after its development; the animal gets off its feed, has a cough and weeping eyes, &c.; the disease is highly contagious, and he believed infectious; the defendant said to him that statements were valueless; he went to a table, took up a book, and said, "So help me God the cattle were sound, and I had not a single distempered cow upon my land."

To Mr. Smythe—The heifers (150) that did not take the distemper were separated from the defendant's cattle; some of them were forty miles asunder.

James Murphy examined by Mr. Maunsell—Was the plaintiff's herd; was present when he purchased the cattle from the defendant; had charge of the heifers; took every care of them; drove them six miles the first day, and nine or ten the next day; delayed longer than usual, in consequence of the multitude of cattle which he had to drive; when he saw Mr. Johnson on his own land he said that the cattle had the distemper, and he pointed out two that had disease; on the next day when the cattle were at Garryhindon the herd said that two of them were sick.

Cross-examined by Mr. Ball, Q.C.—Had the cattle on the field of the hotel-keeper at Shannon Bridge; there were other cattle on that land which had been sold at Ballinaslee; the cattle remained that night at Shannon Bridge; they slept at Frankfort the next night; on the third night they slept at Tinnahinch; paid for the grass; there were no other cattle there; the cattle day, and the day before that at Ballinasloe, were fine days.

To Mr. Maunsell—Prevented the cattle from mixing with other cattle every night.

Mr. George Johnson examined by Mr. Byrne—The herd brought the cattle to his field after the fair; observed two of them lying down on the field, and expressed the opinion that they had the distemper.

Robert Hickey examined by Mr. H. Smythe, Q.C.—Was of the Dublin firm "Hickey and Hanberry;" on the 19th of October sold a sick beast for the plaintiff for £7; she was badly affected with "pleuro pneumonia;" considered that the disease was contagious; the beast must have been sick more than a month; sold other sick animals for the plaintiff.

Owen Duone examined by Mr. Maunsell—On the 14th of October brought a heifer of lot No. 11 to the butcher; on being opened that beast exhibited symptoms of disease; the lungs and other parts were a mass of yellow matter.

Joseph Kilbee examined by Mr. Byrne—Is a salemaster in Liverpool and a grazier in Ireland; several of the cattle were sent to him which had the lung disease; his experience was considerable; the disease was latent about six weeks before it exhibited itself; was examined as a witness before the House of Commons relative to the disease; witness made the sales for the plaintiff; the cattle, if sound, would have brought £6 per head more than they did.

To Mr. Battersby—Saw the cattle in the fair; did not observe them much, but thought at the time that they were sold at a cheap rate; considered that in a fat market, not a store market, both buyer and seller could know that disease existed in cattle if they were thin; Liverpool was a fat market—a town market; Ballinasloe a store or fair market; cattle were often sold as sound that were unsound; adhered to the evidence which he had given before the committee.

Mr. Anthony Allen examined—Is a salemaster; lives in Wicklow; is an extensive grazier; the disease is highly contagious; it did not develope itself earlier than six weeks; had experience of the disease in cattle that had been sold to himself.

Patrick Maher—Is an extensive grazier in Meath; the disease is contagious; it takes a month or longer to develope the disease; a beast whose lungs were a jelly on the 14th of October must have been infected before the 9th.

To Mr. Ball, Q.C.—Could not say whether the disease was in the air, or was communicated by food or touch, or by all of these; but the general opinion amongst those with whom he associated was that the disease was contagious.

Mr. Battersby, Q.C., stated the defendant's case in an able speech. He knew it would be difficult to counteract the effect that had been made upon their minds by the address of his excellent and most plausible friend, Mr. M'Donough. There was not any doubt that the plaintiff had sustained a loss: the question was, who was to bear that loss? The case for the defendant was, that he had 496 head of cattle, in lots of 30 each, and that not one of them was diseased. The beasts sold to other persons were sound; not a single one of them was unsound. The defendant was not only an honest dealer, but a liberal one also, and it would be a hard case if he were now obliged to pay the plaintiff for cattle that had taken the distemper after they left his hands. There were 98 beasts that had been bought in the month of April. The defendant did not tell the plaintiff that all these had been reared from calves, but he spoke of the first lot at which he looked. On the 24th of August there was one beast that was diseased, but the rest were perfectly sound. Could it be held that a dealer was responsible for every head of cattle that might happen to die? The warranty was not confined to cattle: it was given as to horses, and even in the case of an insurance upon life. Suppose a life, insured upon the 24th of August, exhibited on the 14th of October the symptoms of a latent disease, would it be an answer to the widow that there was an invisible germ of disease? The germ might exist, but this was not the disease itself. When disease did arise it was perceptible from the first moment of its existence. The disease was, in fact, an inflammation of the lungs, and could that disease in a horse be distinguished from the same disease in a cow? There was no law of science or art to show the rapidity with which such a disease progressed, but it was palpable that when it existed it developed itself. The fair of Ballinasloe was full of diseased beasts, and as the disease was contagious or infectious, there was an abundant opportunity for contracting it at the fair, even if the cattle had not been for several days travelling along the road to the farm of the plaintiff. What security was there if a man could be held responsible for the breaking out of any imperceptible "germ"? The effect of such a stringent rule would be, that every seller in Ballinasloe would have a board displayed near his cattle with these printed words, "These cattle are not warranted sound." Were they to trust to such a warranty as that relied upon by the plaintiff, it would be a prolific source of litigation. "Germ, virus, warranty," would be three most magical, most potent words, to put money into the pockets of the bar of Ireland. If they sold a horse, and warranted him as sound, any man who understood the subject could pronounce an opinion as to its soundness; but here was a case where confessedly there was no appearance of disease when the cattle were sold; and because they afterwards got distempered, the defendant was to be held responsible. It was a strange and most dangerous proposition. The learned counsel then called evidence for the defence.

Walter F. M'Donough, defendant, examined by Mr. Ball, Q.C.—Resided near Ballinasloe; grazed about 1,100 head of cattle in the year; sold three lots to the plaintiff at the fair; they had been brought from his farm; 27 of the lot of No. 11 had been grazed upon the island of Inisshank, in the King's County; that lot consisted of 30; three of the lot were fed in Roscommon; there were two cases of distemper on the island, one in July, the other in August; sold two at the fair of Eyrecourt to a butcher for £25; that butcher, whose name was Barrett, had gone to America; never had a sick beast since that day anywhere; sold at Banagher 60 that had been grazing on the island; they were perfectly sound; sold 30 to Mr. Eyre, and 30 to Mr. Malone.

Mr. M'Donough, Q.C., objected to this evidence. Would Dycer in Dublin be permitted to give evidence that he sold 60 horses that were sound as an answer to an alleged breach of warranty in the case of an unsound horse?

Mr. Battersby, Q.C., pressed the question.

The Lord Chief Justice ruled that the evidence was not admissible.

Mr Battersby, Q.C., asked his lordship to take a note that he offered to give evidence that every head of cattle on the island was sound, and that he refused to admit that evidence.

His lordship said that the plaintiff could not be expected to meet the case of the sales to other parties, but it was open to the defendant to give evidence to prove that all the cattle grazed on the island which were sold to the plaintiff were sound, and to give general evidence that the cattle grazed on the land were sound.

The defendant then said that all the cattle sold at Ballinasloe were sound; had seen the lots before the fair; was present at the drawing and lotting of them; there were four lots; all were sound; had not the slightest doubt of it; there was no question about his telling the plaintiff that the cattle were sound; when he bought the first lot, defendant told him that he had reared them from calves; it was not true that he had said this in reference to lot No. 11; since the 24th of August no beast had exhibited disease; ninety head of cattle were sent to the island, and mixed with lot No. 11, in the month of September, and remained till December; all of these were as sound as a bell; a book happened, unfortunately, to be near him on the occasion of the fair; he put his hand upon it, and said he had not given him an unsound beast at Ballinasloe; disease might appear suddenly; could not say whether the disease was communicated through the air.

Chief Justice—He would be a wise man who could.

Cross-examination of defendant—Looked at the lots generally; did not examine their heads or feel their fat; whose brand but his would be on the cattle? bought the cattle (30 of them) at Eyrecourt upon the 24th of April, and the others on the 7th of May, at Ballinasloe; could not say in which of these places the lot was bought; the two distempered heifers sold in July and August were of those bought in April or May; made the sale to Barrett; positively said that he did not swear in the arbitration room that he had no distemper on his lands for two years; looked into his books, and found that nineteen months before the fair of Ballinasloe there was a case of distemper in a cow; in 1857 there were two cases of distemper on the land.

Mr. Samuel Garnett examined by Mr. F. Johnson—Saw the stock, and was of opinion that they were sound, and did not know from whence the disease came, no more than the captain of a vessel could say how the tempest arose; had known cattle said to have been unsound turn out to be perfectly sound.

Mr. Peter Aungier—Is a salemaster; cattle which he had seen well at night, were in the morning reported as being ill; had known cattle when slaughtered exhibit disease, of which the seller had no idea.

Mr. Patrick Leonard — Heard the defendant say to the plaintiff, taking up a book (a registry of his), "As sure as that is a Bible, the cattle I sold at Ballinasloe were sound;" always thought a herd could at once detect the disease; was of opinion that the beasts were sound.

The Lord Chief Justice charged the jury. He said it was not necessary for him to do more than occupy their time for a few minutes, in stating the rights of the plaintiff and the liability of the defendant. The question was, whether the heifers that were sold were at the time of the sale all sound, or whether any of them were affected with any disorder? There was another issue—whether, if some of the cattle were affected, they did not affect others? If this were so, the party was liable, not alone for the original damage, but also for the consequences of that original damage. It was a case in which the defendant had warranted that all the cattle were sound; it was in vain to say that the warranty was a puff. It was admitted that the defendant had warranted them. The question was, were the cattle sound agreeably to the warranty? The effect of a warranty was this—it made a man responsible for all defects known or unknown to the seller; and it was no defence for him to say that in his conscience he believed that the cattle were sound. He had given his warranty—he had induced the buyer to purchase upon the faith of the engagement that the cattle were sound, and he had guaranteed him against any loss which might result from the purchase. It had been said that if this were to be the consequence of a warranty, every man at a cattle fair should put up a placard intimating that he did not warrant the cattle. All that he had to do was to hold his tongue and give no warranty at all; besides this, there were insurance offices that would willingly insure cattle and protect the buyer from any loss consequent upon the sale. In conclusion, his lordship said that the jury should look to the gradual development of the disease in the cattle of the plaintiff himself after they became mixed with the cattle sold by the defendant, and consider whether, under all the circumstances, the plaintiff was entitled to their verdict.

The jury retired, and in a few minutes returned with a verdict for the plaintiff upon all the counts—Damages £1,000 sterling.

LABOUR AND WAGES.

Mr. James Howard, of the well-known firm of agricultural implement makers, recently delivered a lecture on this subject to the members of the Bedford Workingmen's Institute. The address, which did great credit to Mr. Howard's powers as a lecturer, is too long for us to give entire. The conclusion is, perhaps, the more applicable to our columns:—

Wages vary in different trades considerably, and where the work is equally laborious. How is this; is it an accident, or is there any law which influences the rate of pay? I think there is. Why should an oak sell for more than a willow or a fir, or even than elm and ash? Simply because it costs more to produce: an oak takes generations to come to maturity, therefore several lots of fir trees could be grown and sold on the space occupied by the oak. I said before that the cost of production rules the price of all commodities; and as labour is a commodity, it rules that also. How so? Why, any awkward fellow can sift gravel and very soon shoulder a hod, but to be able to build a good wall, or turn a nice arch, requires the labour of a practised bricklayer. It costs, therefore, more in time and money to produce a good bricklayer than to make a slab—to produce a good smith than a hammer-man—a good engineer than a stoker. An engineer obtains better wages than a bricklayer or a carpenter; for the same reasons, the bricklayer gets better wages than the slab, *i.e.*, it costs more in time and money to make a youth a proficient engineer than it would do to make him a bricklayer. Pleasantness of occupation and freeness from risk are also elements to be taken into account. A man won't go down into a coal mine and work for the same price as he can get in the light of day. Men don't leave pleasant employments for less agreeable ones without hoping to better their condition. Occupations requiring greater strength or bodily labour than others are also better paid. When men mow grass they get better pay than when trimming a hedge. So with furnace tenders and rollers of metal, where, owing to heat and exertion combined, a good deal of sweat is lost, and a good deal of beer poured down to supply the waste; their wages are necessarily higher, for the simple reason, it costs more to keep them up to the mark. We could multiply such reasons at great length, such as continuous employment; but I hope I have said enough to prove that wages do not depend on chance, but are on the main regulated by some general principle. There is one principle I have not alluded to, but which all will do well to bear in mind, for it not only influences wages, but leads to constant employment—I mean a good character. 'Tis said a "rolling stone gathers no moss," and I do not know what is more likely to make a man roll than a bad character. I intended to go into the question of piece-work, but time will not permit. I like the system, as it enables the workmen to earn higher wages, and the master pays for no more and no less than is done. I never had any difficulty in letting a job by the piece. I hear there are difficulties in other trades, but I think

they would vanish when the system came into operation. 'Tis worthy of remark and consideration, that those trades have made the greatest progress where piece-work has been the rule. It gives the industrious and skilful man a great advantage over the lazy and unskilful one. It also sets the energies of mind to work to find out readier and quicker methods of getting over work; and I hope to see the plan more generally adopted in Bedford. I quite believe it would answer in the building trades. I have no time to enter on overtime. It may do with your slow day-workmen; but 'tis of no advantage to men by the piece. We have hitherto spoken mainly of the labour of the hand: we will now turn to another kind of labour, and this by no means the easiest kind. I mean the labour of the brain, quite as important as the other—to none more so than to the working classes; for it is by the labour of the brain that man's bodily labour is profitably conducted, new branches of industry opened up, new material discovered on which to expend labour. Many of you visited the Great Exhibition, 1851, and were doubtless impressed, as I was, with this idea—What an amount of thought and ingenuity has been expended in bringing our manufactured products to their present high degree of perfection? Why were we before every other nation in the excellence and variety of our manufactures? Simply because we had brought to bear on them more mind, or, in other words, a greater amount of reasoning and intellectual power; and, mark you, 'tis only as we keep in advance of other countries that we shall command the trade. If you could buy as good a saw made in Bedford as in Sheffield, you would not send to the latter place for it. So with the American—if he can buy as good hardware in New York as in Birmingham, he will not send across the Atlantic for it; nor will the French, the Austrians, the Russians, continue to send to England for agricultural machinery, unless we continue to produce better than they can get at home. So excellent as our manufactures doubtless are, we must not stand still, but use every effort, both men and masters, to make something still better. Improved machinery has the effect of saving labour, and therefore was supposed to diminish employment. I am aware that it does so in particular instances; but, as I will attempt to show, the effect is but temporary. There is one very hackneyed but very striking illustration. It is nearly four hundred years since printing was discovered. Great numbers of men were employed in writing and copying books. Owing to the amount of labour, books were very dear. A bible cost £30, so very few people had bibles. The immediate effect of this discovery was, that these writers were thrown out of employment. Now suppose, for the sake of keeping these men employed, or for the love of clinging to old methods, the world had destroyed the presses, can you estimate the loss which would have been entailed on the world? At all events, we should not have wanted the army of printers we now employ. Take, again, the cotton and woollen trades, now about the most important branches of our national industry. On the introduction of the power-loom and Arkwright's spinning machinery, great distress resulted to the hand spinners and weavers of Lancashire and Yorkshire. Suppose they had successfully opposed, as they attempted, their introduction, and stuck to the old method, what would have been the result? Why, not a single hand would now have been employed in the cotton trade in those districts; the machinery would have been transplanted to America or the Continent. We need not, however, travel beyond Bedford to prove that although machinery may for a time be injurious to one class of working men, that it is beneficial to the mass. Some of you are aware that at Well-street foundry we have a new system of making castings by machinery. The moulders, of course, looked upon the machines at first with no friendly eye, for with a machine one man can do as much work as two or three could by hand. It did not do the moulders much good, I confess; nor, I think, a great deal of harm; but how did it affect the other branches? In this way. Last year we made 500 more implements than we could have done without the moulding machines; consequently a great number of smiths, fettlers, fitters, painters, and porters were benefited, whilst the machines only affected the interest of some half-dozen moulders. Again, look at railways. Most of us remember their introduction, and what a hue-and-cry was raised about the ruin they would bring upon coachmen, guards, ostlers, innkeepers, proprietors, and even farmers were dragged in, for we should want no horses, and therefore no horse corn. Well the country has not been ruined, if a few of the class I have named did not do so well as before. We should all be sorry to go back to coach days: 12s. to go to London on the outside of a coach in six hours, &c. Some of us remember the war waged by agricultural labourers against thrashing machines, and how they broke them up and burnt them; but time changes men's ideas, and now these very men refuse to thrash with the flail. Had it not been for the steam thrashing machine after the harvest of 1856, we should have had bread at famine prices, for the old stock of corn was all gone, and we had to live upon the new crop. The demand, therefore, for the new crop was so great, that all the steam thrashing machines were kept in constant work for months. I verily believe, if it had not been for steam thrashers, the 4lbs. loaf would have been at 1s. 4d. Machinery raises man's intelligence. I don't believe in man's doing the work of brutes; I look upon man as too noble to be made a machine of. I remember he is made in God's image, and I hope to see the day when every description of labour which taxes the physical powers of man, shakes his frame, blunts his intellect, and such as is only fit for beasts of burden, will be performed by machinery. Surely it will be better, as in the steam thrashing machine, instead of employing man's brute force in exceedingly laborious occupations, to overcome them, his intelligence shall be employed in directing machinery to perform it. It is a startling fact, that until the introduction of machinery, especially the steam engine, the progress and population of the country went on very slowly; but who can measure all the strides it has since taken? In 1780, less than 80 years ago, just at the dawn of the new era, when machinery came to the help of labour, our population was about 8 millions, now it is above 20 millions; while the increase from 1575 to 1750 was not more than about 1½ millions. The rapid increase in the number of the people, as well as their improved condition, clearly indicate that the means of employment and subsistence had been materially enlarged; and I think you will agree with me that this advance in population and wealth can only be accounted for by the fact that the machinery, which it was feared would diminish employment, has enormously increased it. To oppose machinery, therefore, is to fly in the face of the best friend the working men of England ever had, and is about as wise as it would be to attempt to shut out the light of the sun. Having endeavoured to show the importance of labour, I shall, in bringing my subject to a close, glance at the respectability and dignity of labour. If we turn to sacred writ, we find the praises of industry sounded throughout its pages. We read—"The hand of the diligent shall bear rule." "Seest thou a man diligent in business: he shall stand before princes; he shall not stand before mean men." The patriarchs, the apostles, and even our Saviour himself, by example, showed to their own and all succeeding ages that honest labour was honourable. There can be no question that some occupations are more honourable than others; and every man who endeavours to rise in life does well. Far be it from me to speak lightly of social rank; but I cannot shut my eyes to the fact that in the present day there are amongst us some who set up false standards of respectability—who look down with a stupid, ignorant contempt upon the lower or industrial classes. I am not sure that the ability to produce wealth is not as respectable as its mere possession. I am not sure that honest labour is not as respectable, and as honourable too, as luxurious indolence. I would not confound those who, raised by the industry of their fathers or forefathers above the necessity of toiling for themselves, devote their lives to honourable and useful pursuits; but I mean a class with whom the moving, acting, working world has no sympathy, and which laughs at the miserable, shrivelled gentility which prides itself upon having had nothing to do with trade, and can never embark in any pursuit for the benefit of their fellow-creatures which might bring them in contact with anything so degrading as manual or mercantile industry. These idlers of society are not, however, to be confounded with those of the upper classes who devote their time to honourable and useful pursuits—happily for this country, a class that is becoming more and more numerous. Yes, if you want to find the real "friends of the people," you must not look for them among those who proclaim themselves

such, but among the long list of honourable, distinguished men who are always ready, with time and money, to help forward any project having in view "the health, the wealth, the happiness of the working classes." One word in conclusion. If the working men would rise to a position of greater respectability and influence in this country, they can do so by becoming more intelligent. We are approaching a time when men will be respected according to their knowledge and conduct; and nothing can prevent you from becoming more powerful than you already are, but from remaining less intelligent than the classes above you. A long line of distinguished men has sprung up from your ranks—men whom any class might be proud to rank among their number. Watt, a mechanic, gave us the steam engine; Stephenson, a pitman, gave us the railway. Here are two men, sprung from your ranks, who have done more for trade, and towards developing the resources of this country, than all the mechanical men who ever lived. And have you no men to boast of, who have conferred benefits on mankind of a higher order? Look through the pages of the *British Workman;* and you will be proud of what the world owes to working men. I could enumerate them, but will only remind you of one—a name which will live as long as time lasts; a man of whom the working men of Bedford may feel justly proud, and whose works they will do well to study. I mean the immortal John Bunyan. May you follow in the footsteps of that noble man, and at last, when the labour of life has terminated, enter into rest!

AN ENGLISH FARMER IN FRANCE.

SIR,—My last letter, on the growth of beet for sugar, has rather interrupted my narrative; but I thought it so interesting a subject to your readers, I could not forbear sending it.

Having seen the town of Dunkirk, the country next became of course the object of attraction. As the population is a trifle under 30,000, half a mile from the centre brings you to any one of the nine gates, at each of which is an "octroi" office, and a couple of men to attend to it. I thought, perhaps, they might have asked me for my passport; but, no, that is one of the duties of the *gendarmes*; but I believe you may travel from one end of France to the other, without being requested to show it, unless you stop more than one night at the same hotel.

Directly you are outside the fortifications it is the country; and I will endeavour to describe my first *coup d'œil* of a foreign landscape, to me a most interesting moment.

A straight and well-paved road and footpath; a row of stunted elms on one side, and willows on the other; a canal running parallel (the earth excavated in the making it having evidently been used to raise the road some feet higher than the adjoining land); half-a-dozen windmills and some small white houses with only a ground floor and a garret under the pantile roof; the land dotted with fruit trees, and divided into small market gardens by narrow hedges full of willows polled; and here you have the view.

At the moment, two fine barges were passing, loaded with coals from Belgium. They had a sail each, but the first was assisted by three men and a woman, at the end of a long tow rope, and both were guided by a woman at each helm.

'Twas market-day at Bergue, another old fortified frontier town, 4½ miles distant; so I walked there. As I proceeded, I was indeed surprised at the surpassing richness of the soil. Round Dunkirk it is a blackish sandy loam, which varies throughout this splendid district of 100 miles south (and I am told over Belgium and Holland), in all the gradations of colour and cohesiveness of loam, with a top-soil of a yard in depth, and a subsoil of brick-earth and marl, requiring no foot on the tool which digs it. We have land as fine in England, but certainly not in such a continuous length.

The cultivation is most excellent; leveller, straighter, or deeper ploughing I never saw, and executed with a pair of horses in a most primitive drap plough, so short in beam and handles that, had I not seen it, I never could have believed it possible to have produced such superior work. They go quite close to the ditch, and the few inches left they dig; so not an inch is lost. The land is all as clean as a garden: even the old hedges are hoed; and we certainly might with advantage copy their mode of making them. All is alive. The stakes are nine inches apart, three feet high; and the plashes, at an angle of forty-five degrees, are all tied with a small willow twig at every place where they cross the stakes, the whole being eithered at top, and that also tied to every stake in same manner. It is often not more than three inches diameter, and is the neatest hedge I ever saw, quite impervious to pigs and sheep, and well adapted to arable land. Some may fancy the labour of it expensive, but I think not more so than ours. It is sometimes quick, but often elm; the seed of which is sown to procure the plants, which are inserted in a single row.

Some grass orchards I have seen enclosed with a live hedge, six or seven feet high, of hornbeam, as large as your arm or leg, a very few inches apart, and the branches interwoven and tied, as the other; it is a fence for a lion, and, like the other, taking but a little space: both these are worthy of imitation.

One hundred acres are here considered a good-sized farm: many are owned by the occupiers.

I gave you, in a few lines back, my first view of this immense vale; I will now, having penetrated some miles into it, endeavour to depict its general appearance.

I expected to find the country have a very dotted appearance, from its numerous subdivisions among small owners; but it is not so, the marks being small square stones, half buried, and no "grass baulks" being left; and all now being ploughed for wheat or spring crops, I could often fancy myself in a level parish in England, under the (recently altered) old "common-land" system. The land has the appearance of immense ploughed fields, with occasionally smaller ones, of the richest grass, nearly all water-meadows, the ditches on both sides being thickly planted with willows. Sometimes apparently unmeaning rows of tall branchless wych elms are seen, and always on the sides of accommodation-roads to the farms, and now and then in square clumps, like Indian topes, giving an appearance in the distance of a wooded district, which it is not. Windmills, barns standing singly, small round ricks of corn, cottages and square-enclosed farmyards—all combine to make a pleasing landscape, for a flat one. You may consider this a picture of the whole country.

They were wheat-sowing, and I saw one harrow drawn by two men, which may give you some idea of the tenderness of the soil. They are excellent seedsmen, seldom drilling the wheat, but generally sowing five pecks an acre, and ploughing it in with one horse. It lies usually in large lands, and the smaller pieces seem often to have been ploughed many times one way, so that no furrow is seen, and all slopes from centre to

the boundary. What furrows they have they seem carefully to "spit" out. I suppose they are anxious to get rid of snow and rain-water quickly; but too much of that I have never seen, for I am sure many five months of summer are much wetter than the last five we have had here. Their course of husbandry is—betteraves; wheat; oats; clover, mowed often three times; bitteraves; wheat; oats; then perhaps potatoes or colza for seed, or beans; and then wheat for last. The wheat is harrowed and well-rolled in spring; cut with a bagging hook, shocked with a hood sheaf, and harvested as it ought to be, from what I saw of the dry samples of white wheat in the markets (brown is not much grown). It is thrashed with a flail, and sold by the hectolitre, *i. e.*, 200 pints, worth now about 16s. 8d., *i. e.*, 5s. 6d. per bushel; bread and gin being the only cheap things here. The former is three pounds for 3½d. Straw delivered is worth 5d. per truss.

The oats are generally white, and are harvested in the same manner; and of them the only thing worthy of remark is, the very small quantity of seed they give to them: they are worth about 3s. 6d. a bushel; they grow great crops.

The clover they make like corn. They tie them in little bundles, and set them up like corn sheaves; consequently it is all woefully made too much, put in little stacks, and when sold at £3 10s. a load is delivered in these same bundles, weighing 9 lbs. each, without a tilt; consequently, if delivered in damp weather, not worth much after a fortnight's housing in a hay-loft. Their hay is made much as ours; and did they not stack and deliver it in the same ridiculous way as the clover, it would be of excellent quality: they are both the same price. Extraordinary that these capital farmers should not have copied our admirable manner of stacking and trussing hay! I should fancy they grow large crops of clover, as I saw many pieces being cut, for soiling the cows and horses, the third time, at the rate of a load an acre. This, of course, is never made into hay.

The colza is sown in beds in the latter end of July, and transplanted (in land manured) in October, in rows across four-step lands, one foot from row to row and four inches in the row. It is cut in July: a good crop is thirty bushels an acre of seed, worth 6s. per bushel. The land is generally immediately ploughed, and sown with white turnips (like our six-weeks' turnips), which come off in time for wheat. The disease of the potatoes has troubled them like us, but I think not to the same extent. It has for some five years past been gradually becoming less; they grow about ten tons an acre; the best worth £3 5s. per ton. Peas they seldom grow. Beans they do occasionally, which they principally give the fatting hogs. Barley is little sown in this district.

You see their prices are about the same as ours, so that with the advantage also of the betteraves, I do not think an English farmer could extract more gross return per acre than they do; and this, added to the heavy stock of cattle they keep, which being fed on bought food has almost no limit but the pocket, make a small farm here a good living. They are a most frugal race, and their great ambition is to save and invest their accumulations in the purchase of land, which fetches an enormous price. A highly-respectable notary informed me 2½ per cent. was considered a fair return. A very great proportion farm their own property.

Leases generally extend to nine years. They have not restrictions in cultivation like us, and the repairs are generally done by the landlord, the farmer providing food the while for the men; but all here is so solidly built of brick and stone, that the repairs are trifling. The barn and stable-doors being all arched, look like the buildings attached to an old monastery or castle, more than an isolated little farm of the nineteenth century. They certainly are a contented happy people, and most industrious. On market-days the son or father, generally both, with mother or sisters, take their covered waggon of corn themselves; pitch it in the market-place, and, when sold, return in the same manner, the exact quantity and price being taken by a policeman and signed by the seller. I never saw such exact statistics as are taken here by Government in everything. I fancy it will be interesting just now, as the question of agricultural returns is so much agitated in England, if I some time send you an account of the progress here made therein, and their manner of doing it; but I am trespassing on your space. My walk to Bergue I will finish in my next, with their cattle management, and the extraordinary but very general treatment of the pleuro-pneumonia.

After a few days' stay at the principal hotel at Dunkirk at the moderate expense of seven shillings per day, I took the rail for Lille.

This is the northern railway running from Dunkirk and Calais to Paris, the Belgian lines running into it. It is a most profitable affair. The carriages are better than ours: first class more silkily lined, and more softly stuffed, and with hot water tanks for the feet; the second also have cushions and stuffed backs; and the third are exactly like our second. The pace is very slow—fifteen to twenty miles an hour; but the price is cheap—first class for fifty miles 6s. 10d.; 66lbs. of luggage is allowed each passenger; all above is charged, but very moderately. The grass grows between the rails, the station-houses are inexpensive, and all seems done cheaply for profit. The crossings were all on the flat (no bridges), with a cottage at each for the *woman* who has care of it. She stands with her folded flag extended in her right hand, as you pass, with a uniform—black glazed hat, white cap, blue cape, and wide red collar. Nothing more is worthy of remark but the fences: they are the same all the way, made of oak *laths*, about a yard high, upright, four inches apart, with two longer ones tied together along the top; and at every five feet an oak post, of which a pole of six or eight inches diameter would make four, the whole being tied together by three *double rails* (if I may so call them) of iron wire, which are twisted round each lath the whole way, and the two tie-laths on the top are served the same. It is stronger than you would fancy, has stood seventeen years, and with new posts will stand many longer. It is good against sheep and hogs, and might often be economically applied at home—a good protection to a young quick near a farmyard. The same sort of landscape prevails the whole way (as I have described it), with the exception of some rising ground about Cassell (half way). I saw two or three small hop grounds, on ridges much narrower and higher than ours; but I will describe their manner of management at the same time as I speak of their malt and beer.

A long delay took place at Calais junction, waiting for the London train, during which time I was much amused at the *sang froid* of a Zouave in a first class carriage; a little sallow man in yellow leather leggings, blue breeches large enough for three, embroidered jacket, and red cloth cap—in Algeria they put on it the white cloth, which makes it a turban: you might readily fancy him a Turk. The reason he was in a first class is, all soldiers and officers here have the *entrée* of railways and theatres for *one-fourth* the price of other people—a great advantage to the rank and file of the infantry, who have only a halfpenny per day. This is the fact; and very happy and content they are. Of course all necessaries are found them; and I am not at all astonished at their predilection for military life: they have little to do.

In time I arrived at Lille, the principal manufacturing town in all France: its Manchester, with a population, including a radius of two miles, of 300,000. It is surrounded with windmills. There is a spot from which you may count 200. I have counted fifty in sight at once frequently. Some are for oil. Few Englishmen stop here, as all haste on to Paris; but it is worth a couple of days to the tourist. About 400 English are here resident, mostly operatives. Very few speak English, none much; but in a few years that will be altered, as now it is taught at all the public schools, to which *all go*. A better education may be had here for *one shilling a week* than in many parts of England for £1. Every boy has to undergo examination, and all are taught mathematics.

All seem thriving here under the strictest system of protection. No one has any fondness for free trade. Government manages everything. You cannot set up a business without leave from the mayor. They are very jealous of us, as we either undersell or outdo them in everything. Anything English is valued. How many times I have been asked if English razors are very dear, as they are so superior to French! Many wealthy men are here. Money is worshipped as much as in England; more so, for those who have it keep it. You do not find the noble examples of self earned fortunes spent like princes, and in doing good as we do at home.

Last Tuesday was held here the yearly cattle show of eight surrounding departments, viz., Novd, Calais, Somme, Aisne, Oise, Seine-et-Oise, Marne, Seine; and it is considered a very important meeting. The abattoir in which the cattle were shown was ornamented with a profusion of tri-coloured flags, and a pavilion was erected for the notabilities who distributed the 38 prizes, which amounted to £342. Agriculture is particularly patronized by the Government; all is done to assist it; and at the introduction of a new plant, or manufacture connected with it, it is not unusual for the public money to be lent to the farmers to try it, as was done many years ago at the introduction of the *betterave* for sugar (by-the-bye, there is a new plant, called *sorgho*, likely in some parts to supersede the *raves:* I will send you a succinct account of it shortly).

The number of bullocks exhibited were 80, cows 41, calves 10, sheep 15 lots, pigs 27. The first class were sixteen Flemish beasts, from two to three years old. They are very useful animals; dark red; much like a coarse Devon or Sussex. They had evidently been well managed, from their size—generally 14 hands, and one 15 nearly—and not so *very* long in the leg. Not very fat—fat animals are not relished here, as, from their mode of cooking, the fat does not come to table: all is boiled or *baked* to rags; nothing like our English cooking. As to a good floury potato, no one knows what it is.

The first class had three prizes of £28, £24, and £20, and two were "honourably mentioned."

The next lot in same class were 12 more, same breed, from 3 to 4 years old; they also had three prizes of £28, £24, and £20.

The second class consisted of three lots. The first were Flemish bullocks, without reference to age; these had three prizes of £16, £12, and £8. The second lot were six Courtois bullocks (a place near the Swiss frontier), a very cloddy animal; but they seem to have many breeds there. Prize 1, of £16, was something like a very coarse Ayrshire; the second prize, of £12, more like a Hereford; and the honourably mentioned was a little thick dun bullock, like a bad Highlander.

The third lot were 27 of all breeds: many were crossed with Durham. Prize 1, of £16, was like a leggy York, with roach back; prize 2, was £12; and prize 3, £8—in my opinion, the best half-bred English of the lot.

The 41 cows were better than the bullocks: I may say they were excellent. The first prize, of £12, was thorough-bred English (of course bred in France, the property of the Marquis of Verdun, of D'Ancy Manche, in Normandy); not large, but very neat; her *live* weight was 230 stone; that would be about 150 stone dead. He sold her for £55 to a butcher, who expected to get a prize with her at a Show at Bergues this week. Second prize, of £10, was an English roan; very good also. Third, of £9, was a Dutch cow; fourth, of £8, was half-English and Flemish—very neat, but small; fifth, of £7; sixth, of £6; seventh, of £5 10s.; eighth, of £5; ninth, of £4 10s.; tenth, of £4; and some honourably mentioned. I would not wish for 41 more useful cows.

The fourth lot were 27 cattle, in droves of four and five each. Many of these were a distant breed (I believe, Courtois), very thick and heavy, 13½ hands high (I like to speak within bounds). There was only one prize of £20 in this lot, and that was given to five yellow dun bullocks between five and six years old, which had evidently been worked; and handsome they looked, no doubt, in their harness. There was not a single polled cow or beast, and they were all trimmed; the latter was a pity.

Ten fat calves come next in the list, generally Dutch bred, from 11 weeks to 3½ months old; nothing particularly good. There were two prizes of £6 and £4.

The sheep were divided into two classes: 1st, young sheep, without reference to breed. The first prize of £16 was for a lot of half-bred Flemish and half-bred Down yearlings; second of £12, for a lot of 14 months old same breed; third of £8, for some 1 month old do. All had their tails bobbed short, and were shorn: the last lot cut 10lbs. wool each (10d. per lb.), and would weigh 11 stone each. The 2nd class was divided into two lots; one without restrictions, and the other merino or half-merinos. The first prize of £12 was for some three-year-old half-bred Flemish and Leicester very big heavy sheep; the second, of £8, for some same breed two-years old; and the third of £4 for half-Flemish half-Down. They told me the wool of the Down cross was worth more than the Leicester cross.

The merinos and half-breds were enormously fat; I never saw fatter. There was only one prize of £12, and that was given to half-merino half-Leicester. This wool does not fetch the highest price. I shall know the live and dead weight, all in one of these lots.

Pigs were good. Short-legged, hardy, white hogs, two prizes of £4 and £3 were given in class 1 (all French breed), and three of £4, £3, and £2 in class 2 for cross-breeds. This concludes the list of cattle.

At 3 o'clock the Prefect of the Department, the Inspector-General of Agriculture from Paris, the Mayor of Lille, their secretaries, and others, all in diplomatic blue uniforms, cocked hats, and swords, took their seats under the Pavilion, while the brass band of 1st Dragoons amused the crowd. The Prefect began by congratulating the people on the progress they had made in agriculture in the north, combining it with manufactures, by feeding the cattle on their refuse, making Lille an especial place of attraction to all who had an interest in land. He thanked all who had assisted, and the many who had come from distant parts to do honour to the meeting. The Government was anxious to give every encouragement possible to agriculture. "The Emperor applies himself energetically and at all times to the agriculture of France: to raise it to the utmost of his power was his most earnest desire. He depends on you to assist him in this good work, and in that hope I am happy to join you in exclaiming 'Vive L'Empereur.'" The Inspector-General then rose, and in the name of

the Government and the judges of the show begged to bear witness to the improvement every year made in the agriculture of the north of France.

The recipients of the prizes were nearly all farmers, and in appearance respectable men, about the same as our 200-acred tenants at home; but in their homes what a difference! what a life of discomfort, compared to the same men in England! I have been to two of their houses, and shall go to a third next week (one of the strongest tobacco-growers about here), to which I shall devote my next letter, and will now conclude.

AN ENGLISH FARMER IN FRANCE.

Lille, March 29, 1858.

THE VALUE OF FURZE AS FOOD FOR CATTLE.

The following are extracts from the testimonies of respectable agriculturists; addressed to the editor of the "Cork Daily Reporter":

From Rev. Benjamin Williamson, Old Dromore, Mallow—"I have been using furze for horses these last three or four years, cut with a chaff-cutter. I commenced this winter on the fourth of October, and am feeding *all* my horses, for pleasure and otherwise, to the number of twelve, and a yearling from that time to the present, and hope to continue doing so for another month. They get nothing else, and are in capital condition. One of the riding horses is rather too fat. I have two furze meadows, each about two acres, and have cut every second year hitherto; but in future I mean to cut every year, as the second year it becomes woody. The land on which the furze is grown is very poor, not worth more than 7s. Of course the richer the land the heavier the crop. I am cutting some two years old for litter, and think of sowing another field this year for that purpose. Sow with barley or oats under the harrow, about 15 lb. to the statute acre. A donkey can work the chaff cutter without bruising, which with young furze is not necessary. By hand-labour (though mine is inferior to Richmond and Chandler's £10 cutter which I intend purchasing) two men and a boy feeding will cut in an hour sufficient for twelve horses. Four hands working got four firkins (equal to bushels), a little packed at night, and no hay. There is a good deal of grass growing with the furze, which is much relished. The other horses don't get so much, but always get a couple of gallons mixed with their oats, which makes them masticate the latter better. The furze is mown daily with an ordinary scythe. The first crop I sowed without corn, but gained nothing by the sacrifice, as it is very slow of growth the season it is sown, not more than a couple of inches in length."

Richard Barter, Esq., M.D., St. Anne's, Blarney—I have been using furze for nearly twenty years, I prepare with a chaff-cutter, I have five farms, and in all have water-power. The furze is cut very green, with a scythe, every year. It is far superior to hay for cows and horses, and the yield of inferior land is superior to the best meadow."

William Crooke, Esq., J.P., Derrun, Coachford—"My mind is made up, after more than twenty years' experience, that furze is the most valuable forage plant we possess in scarce seasons. Farmers from great distances come here to buy furze by the half-acre, at high prices, which they could so easily grow on their own farms. The lowest price I ever got was £4 per acre (statute), which was not half its value. My plan of culture—sow 28lb. of seed to each acre, as you would clover seed in oaten tillage the day after sowing the corn; the oats will not injure the furze, nor the furze the oats in mowing, unless the oats be a very heavy crop, and should lodge, in which case it is sure to kill the furze. You will have a great crop every succeeding year—say from four to eight tons. On no account let it stand more than a year uncut; it gets woody and bad for food. No beast should be allowed in the field at any time, except that which draws in to the farm yard. It requires no manure, no weeding, and mine is yielding abundantly, after more than twenty years' constant mowing. After many years' experience, cutting every year, it has been rising every year in my estimation. Good as it is for food, it is equally good for litter. I have found that furze passed through the cattle-house is just as good manure as if wheaten straw had been used. For food it must be used fresh: it will not keep cut and bruised a second day; any left ought to be swept into the manure pit. Water-power works a powerful cutting machine, bought from M'Kenzie, Cork; works also a Gardner's turnip-cutter, and it is astonishing in how short a time turnips and furze are prepared for twenty head of cattle."

Mr. Hawkes, Passage West, adopted Mr. Crooke's plan of cultivating and preparing furze, and found it to be of the greatest advantage in supporting cows and horses. This year the herdsman varied the food with great advantage, giving half furze with some turnips and hay, and never had them in such a condition before.

Mr. Samuel Lane, steward to the Hon. Mrs. Austen, Hadwell, Aghada, writes that he has had many years' practical experience of its great utility as food for horses and horned cattle, and its value as a substitute for hay. He had for many years the superintendence of two large farms; and on one he worked on his own account, furze propagated by plants from seed in previous spring, in November, and mown every year, turned to best account. Poor light or mountain land, which would be useless for other crops, will bring good furze, by ploughing and digging, sowing 20lbs. seed to the acre. Any farmer so devoting five acres of poor land would find that they were the most valuable and useful part of his land. His way of preparing was, first the cutting spade and pounder; but in 1854 he bought a furze cutter from, as he truly says, that first-rate seedsman and machine-maker Mr. Thomas M'Kenzie, Camden-quay, Cork, for eight guineas.

Six horses, one mule, four working bullocks, and twenty heifers, were supplied every day. The horses got three firkins well filled every day; the mule two; working bullocks three each; heifers one each; a few firkins to the milk cows; working horses and working bullocks got a little hay also. One man and a boy provided and prepared all this food.

ACCIDENTS CAUSED BY AGRICULTURAL MACHINES.

It is but a short time since machines propelled by horse, water, or steam power have been employed to any great extent by farmers in this, or in fact any other country, the great proportion of the labour bestowed on land, and nearly all the work of the whole farm, being performed by manual labour, or the direct traction of draught animals. With the advent of the application of machinery have come the dangers resulting from its use, involving the loss of life and limbs to its operators. These accidents can, however, be prevented to a very great extent, by care and prudence. When machinery was first extensively used in manufactures, accidents were of every-day occurrence. Limbs were cut and torn from the body, and even the whole frame mangled in the worst manner. But at the present time such agonizing scenes seldom occur, and when one does happen, it is often in using some new machine with which the workmen are unacquainted, or, what is more generally the case, the victim is a new hand, often a few hours only since he first entered the building. Now from these facts we may understand that the principal cause of such accidents is either carelessness, or ignorance of the dangers resulting from the use of machinery. At the present time, machinery for manufacturing purposes is built with reference to obviating any danger which might arise from its use. Wheels are guarded and belts placed in positions least liable to come in contact with the dress or persons of those in attendance, or in many cases entirely boxed in; and in all well-regulated factories, every precaution is taken by which life and limb can be protected. The workman also has a set of rules by which he is guided in all necessary handling of his tools or machine, and the young beginner, who is not wise enough to profit by the experience of his seniors, soon learns a lesson which he will never forget, impressed upon him as it has been in blood.

Our farmers are at present in the condition of the manufacturing operatives of twenty-five or thirty years ago, in as far as ignorance of the manipulations of machinery, and they have to learn in the same manner those have done. But much of the experience of the latter class can be profitably applied by the former, and with great ease. We will give a few hints on this subject, which will be found of practical utility.

1. Greater care should be taken in handling machines driven by horse power than is necessary when steam or water power is used, the motive power in the former case being more liable to start when not wanted, and that in either direction. The animal should therefore either be detached, or the machine locked when it becomes necessary to handle the working parts. With a properly constructed steam engine or water power, this is never, or at least seldom the case.

2. In putting on or taking off belts, be sure and have your feet firm. Never put your thumb or fingers between the belt and the pulley. The safe handling of belts cannot be performed by a mere novice; practice is always essential.

3. Never pass before a mowing machine to put anything to rights. If you stand at the back or upon the machine itself, there is little danger, otherwise much; as several serious and fatal accidents during the past season give evidence.

4. Study the details of all your machinery with an eye to the liability of danger to yourself or servant, and devise means by which it can be avoided, and you will confer a benefit on the whole farming community.

5. Give preference to machinery that, combined with other good qualities, is constructed with reference to the avoiding of injury to the person who has it in charge. Along with the observance of this advice, never allow a person under the influence of liquor to come near any kind of machinery. The whisky jug is often the cause of much suffering in this way as well as in others. If the reader will remember these hints, they may prevent many sad accidents.

"GOD SAVE THE PLOUGH."

BY MRS. SIGOURNEY.

See how the glittering share
Makes earth's bosom fair,
  Crowning the brow;
Bread in its furrow springs,
Health and repose it brings,
Treasures that mock at kings—
  God save the plough!

Look to the warrior's blade,
While o'er the crimson'd glade
  Hate breathes its vow—
Wrath it unsheathing wakes,
Love at its flashing quakes,
Weeping and woe it makes—
  God save the plough!

Ships o'er the ocean ride,
Storm wrecks their banner'd pride,
  Waves whelm their prow—
While the untroubled wain
Garneth the golden grain,
Gladdening the reaper train—
  God save the plough!

Who are the truly great?
Minions of pomp and state,
  Where the crowd bow?
Give us hard hands and free—
Cultures of field and tree—
True sons of liberty—
  God save the plough!

THE AGRICULTURAL VALUE AND USES OF LIME AND MARL.

Among mineral manures none are more highly valued than lime and its various admixtures with marl and other earthy substances. That lime furnishes any absolute nutrition to the plant is extremely doubtful, as very few traces of it are ever found in analyzing the different kinds of vegetables. Its great advantages as a fertilizer appear to be almost entirely derived from its chemical action on various ingredients, and in a certain mechanical influence which often acts favourably in improving the texture of the soil. In order to use lime with any degree of certainty as to its effects, a partial knowledge of its chemical and mechanical uses is absolutely necessary. It is obvious to all, that this substance on different farms produces the most contrary effects. While, used with discretion, on some soils it produces the most astonishing results, it is known to be attended with really ruinous effects when applied to marly and calcareous soils, without they have previously been very much reduced, in which case lime can be applied in small quantities in conjunction with other manures. Lime is used with the greatest advantage on peaty soils, and those which contain a large amount of vegetable matter—clayey soils, which need to be acted on by its mechanical effects, in rendering them more light, open, and easily cultivated—soils which are barren by the existence of green copperas (proto-sulphate of iron)—those which need potash, and, as a general rule, most soils which are sterile and worn out from long and exhausting systems of cultivation.

Marl varies very much in its composition in different localities, but is generally known as a mixture of various kinds of earth with lime; and its value is chiefly estimated by the amount of this mineral which it contains—hence we have clayey, sandy, and earthy marls. Although owing its fertilizing qualities mostly to its per-centage of lime, its other ingredients are often highly valuable, especially when applied to opposite formations of soil. Thus sandy marl would prove the best of fertilizers for stiff clay. In England the value of marl has long been recognized, and we are informed that leases were granted as far back as the reign of Edward I. which compelled the tenants to make use of it, but its use is much less employed since lime has become more known.

The farmers at one time were so confident of its virtues, that they depended almost entirely on it, and made it supersede the use of dung, by which means they were enabled to sell large quantities of hay and straw. But this course, although it enabled them for a time to raise good crops, eventually reduced the soil, and thus has arisen the old saying which was cited by Barnaby Goorge, who wrote so long ago as the middle of the sixteenth century, that *"lime and marl are good for the father, but bad for the son."* But this saying, like many others of ancient date, is evidently an error when they are judiciously employed in connection with animal and vegetable manures.

As the value of marl is computed by the quantity of lime which it possesses, that value can be roughly ascertained by the effervescence which ensues when vinegar or muriatic acid is poured on it, after which a chemical analysis, if deemed expedient, would show the exact per-centage of this and all other ingredients. When a bed of marl is first found, and no good reasons are given for its use, farmers should be careful to use it first in small quantities, and thus experiment with it until they are perfectly satisfied of its real worth. In order to get poor land into a good state of productiveness by lime and marl, it is also necessary to manure highly with animal and vegetable fertilizers, such as stable manures. But where it is impossible from the scarcity of these manures to bring it up in this way, the cheaper but slower process of ploughing-under green crops can be resorted to with almost equal success. Clover is perhaps the best crop to turn under, when the land is in good heart enough to produce it; but when too poor for its production, buckwheat can always be relied on until the soil is sufficiently replenished for the growth of clover or lucern.

Farmers possessing fertile land must be aware, by what has been previously said, that if they find the use of lime or marl beneficial to their crops, they must not rely too implicity on this class of (mineral) fertilizers, but rather increase than diminish the amount of farm-yard manures; for the increase of the crops which is produced by liming rather tends to exhaust the soil of its necessary ingredients, and to destroy its fertility; so that while the use of lime is continued, it becomes more than ever important not to decrease the use of other manures. All this extra labour and expense bestowed on this system of cultivation will be doubly repaying; for if there is any profit in raising medium crops on a farm, this profit rapidly swells when the same land is made to produce large and abundant returns.

Most marls need to be drawn out and exposed to the action of the weather for some months before it is intended to use them, that they may be pulverized and made suitable for application by the action of the weather. Some kinds are so stiff and unmanageable, as to need the action of both the summer and winter elements to reduce them to a proper state of fineness for application.

Lime should not be applied in its caustic state, except to lands containing large quantities of inactive vegetable matter, and on those in which organic manure is contained unchanged and ineffective. When partially slacked and reduced to fineness by exposure to the air, it possesses sufficient caustic properties for all other soils, if applied soon after being slacked. Mild lime, after being reduced to a powder, is more beneficial to all lands, with the

exception of the above, as it does not exhaust the vegetable matter in any greater quantity than is required for the growth of the crop. The trifling saving which might be gained by the immediate application of caustic lime would never pay for its injurious effects on all soils, excepting those which contain large quantities of organic matters requiring to be dissipated. Besides, caustic lime should not be used in contact with seeds or herbage; and when applied to clays for the purpose of improving the texture of the soil, it frequently causes quite the contrary effect, as it unites in a mortar with the clay, causing it to harden and form cakes. In most all cases, we think it is self-evident that lime should be applied after air-slacking, in its mild (carbonated) form.

We are frequently asked whether lime will benefit soils associated with limestone rocks. Such soils frequently contain lime in sufficient quantities; but this is not invariably the case, as soils sometimes resting on limestone, or abounding in loose limestone and shells, are frequently devoid of lime in such a form as to be useful. We can only account for this phenomenon by supposing that the soil was originally derived from some other source than these rocks, or that the firm texture of them has prevented their crumbling enough to benefit the land. Thus it often proves that liming is beneficial on what is called limestone land. We should advise its use in small quantities at first on such lands, without the owner is perfectly satisfied by analysis that his land is totally deficient. By pouring muriatic acid or vinegar on a small portion, he can at least tell if it contains lime to any considerable degree.—G. T. H. in the "Country Gentleman."

SEA-WEED.

This is a valuable manure for almost any description of soil, from the light sands to the heavy and viscid clays. No one, who has experienced the beneficial results attending its application, will doubt its value, especially when applied as a top-dressing to lands in grass. The most proper season for removing and spreading it, we are informed by those accustomed to its use, is immediately after haying; or if it cannot be conveniently done at that time, the work may be deferred till after harvest. It is a judicious plan to mix this weed with loam or muck, forming it into a sort of compost. The mass should be frequently turned. If convenient, ashes, lime, plaster, and clay may be added, depending considerably upon what kind of soil the mass is to be applied to; but it should not be permitted to decay in a heap by itself, as in this case the limited amount of fibrous or ligneous substance contained in the mass causes it to decompose almost "to nothing"—a slight residuum only being left after decomposition, and this of a very weak character, and not, perhaps, of sufficient value to warrant its application to the soil.

Muscle shells, and the rich, unctuous and viscid sand abounding along the coasts and on the shores of creeks, are other important and valuable elements of fertility, and when spread upon soils of every description, produce highly beneficial results. This sand is composed principally of animal and vegetable substances, intermixed with the exuvia of testaceous and crustaceous insects, saline particles, and an extremely fine sedimentary substance deposited by the waters of the ocean, together with carbonate and hydrate of lime, animal matter, and earth. The intermixing of these several substances constitutes that highly efficient fertilizing mass denominated sea mud, or "flats."

When a farmer can obtain a sufficiency of this article with which to dress his lands, he need not fear the failure of his crops for lack of manure. Sea-weed, and sea mud, or "flats," constitute an excellent substitute for animal excrement and compost, and almost supersede the necessity of the latter, in ordinary husbandry. If the weeds and mud should be taken out after haying, and placed in the barn or compost yard, with common muck, mould, and vegetable matters of a succulent and perishable character, or thrown into heaps with forest leaves, straw, weeds, &c., it would decompose, and by the next spring furnish an invigorating manure for every description of crop.

There is abundant testimony of the value of sea-weed as a manure, in the books. Many years ago, the Highland and Agricultural Society of Scotland charged an intelligent committee with the labour of investigating its composition and value, and their report is highly favourable. Dr. Holland, in his "Survey of Cheshire," says, "The ground thus manured not only gives a larger produce of potatoes, but is in a state of excellent preparation for a succeeding crop of either wheat or barley." In a work by the Rev. Philip Falle, upon the island of Jersey, whence we obtain the famous Jersey cattle, he says that "Nature having denied us the benefit of chalk, lime and marl, has supplied us with what fully answers the end of them in husbandry—it is a sea-weed, but a weed more valuable to us than the choicest plant that grows in our gardens. * * * Being spread thin on the green turf, and afterwards buried in furrows by the plough, it is incredible how, with its fat unctuous substance, it ameliorates the ground, imbibing itself into it, softening the clod, and keeping the root of the corn moist during the most parching heats of summer."

We are aware that our friends on the sea-shore, who have access to this plant, value it highly. We suggest whether it has not sufficient value to justify its being collected away from our immediate shores, and landed up the creeks, and in such places as to bring it into the vicinity of a large extent of farming country.

THRASHING MACHINES.

The monthly meeting of the members of the Highland and Agricultural Society of Scotland was held on Wednesday, the 24th March, 1858. The Right Hon. Sir John M'Neil, K.C.B., in the chair.

Mr. HOPE, Fenton Barns, said—In introducing this subject, perhaps a slight sketch of their history might not be uninteresting, particularly as it enables us to review the progress that has been made in mechanical science, the great saving of labour, both human and animal, that has been effected, and the large additional quantity of food produced, by the more perfect manner in which grain is now separated from the straw. In early times this separation was performed by laying down the straw with full ears in a narrow circle, named in holy writ "the thrashing floor," and treading it out with the feet of oxen. It was one of the benevolent edicts of the divinely commissioned Jewish Lawgiver. "Thou shalt not muzzel the ox when he treadeth out the corn." This method is still followed in Eastern countries; and even at the present day, as we learn from the latest authorities, in some of the States of America, a large proportion of the grain is trodden out by horses. With grain easily raised, and cheap in comparison to the wages of labour, and in hot and dry climates, which renders grain more easily shaken from the straw, this manner of performing the work may not be so unsuitable as might at first be supposed; still, under every circumstance, there must be great waste of the blessings of divine providence. It is believed that the Jews possessed instruments which may be described as thrashing machines; but these were only heavy pieces of wood, sometimes shod with flints, sometimes revolving cylinders or teethed wheels, and being dragged by the oxen over the grain, in a manner multiplied the number of their feet in contact with it, and, consequently, the work was done in less time. I believe it is not known when that simple implement the flail was first invented or used as a thrashing machine. It was well known to the ancient Romans, and at present is in general use throughout the continent of Europe. Even in some districts of England it is still a common implement on large farms, at least it was so before the repeal of the corn laws. In Scotland it has long been restricted to the Highland crofters. Early in the last century there are various accounts of attempts made to construct more complicated machines to save labour in beating out the grain. One, if not the first, of which there is any record, was by Mr. Michael Menzies, an Edinburgh advocate, who resided in East Lothian; his brother being proprietor of Letham, near Haddington, and also sheriff of the county from 1718 to 1725. A patent was obtained for Mr. Menzies' machine in 1732, and it was declared by the Society of Improvers in Scotland, "to be likely of great use to farmers, both in thrashing the grain clean from the straw, and in saving a great deal of labour." It was on the principle of driving a number of flails, which were made to revolve round a cylinder, by means of water power. But from the force with which it was wrought the flails were soon broken to pieces, and the invention proved a failure. Another thrashing machine was invented about 1758, by Mr. Michael Stirling, a farmer in the parish of Dumblane, Perthshire. This machine was similar to the flax scutching mills of the day. It has been described as a vertical shaft with 4 crossed arms enclosed in a cylindrical case 3½ feet high, and 8 feet diameter. Within this case the shaft and its arms were driven with considerable velocity. The sheaves of corn being let down gradually through an opening on the top of the box, the grain was beaten off by the arms, and pressed, with the straw, through an opening of the floor. The grain was separated from the straw by riddles shaken by the mill, and then cleaned by fanners, also driven by it. It was reckoned the great defect of this machine that it broke off the ears of barley and wheat instead of beating out the grain. It succeeded better with oats, and was used by Mr. Stirling himself, and also by some others for several years. It was driven either with water or cattle. A few years after Mr. Stirling's machine came into the partial use it attained, mills of a similar construction were introduced into Northumberland by Mr. Edward Gregson, only they were worked by hand power. Some time after this, or in 1772, Mr. Oxley erected a thrashing machine at Flodden, moved by horses. The corn was fed in betwixt two *fluted rollers*, and struck by switchers, placed at 3 inches distant, on the cross arms of an open drum: the scutchers were made of wood, and attached by leathern straps, or *hung on hinges*, as they were described. Thereafter, or in 1773, Mr. Ilderton erected two thrashing machines, one at Ilderton, and another at Hawkhill, both near Alnwick. They were worked by horses, and were made to rub the grain out by projecting pieces of wood (on the circumference of a large cylinder) rubbing against several fluted rollers. He used these machines many years, but it was frequently necessary to put the straw twice through before it was perfectly clean. Sir Francis Kinloch, of Gilmerton, who was a man esteemed, in his day, for his mechanical knowledge, had seen Mr. Ilderton's machine, and also the common flax mill. He endeavoured, by combining the two, to produce a workable machine. Sir Francis had a large model made; and as it could not be wrought by hand power, he sent it to Mr. Andrew Meikle, miller, and maker of barley and flour mills, at Houston Mill, Prestonkirk, that its effects might be ascertained by the water wheel of Mr. Meikle's barley mill; but in making the trial the model was torn to pieces, and a like fate befel a machine of full size, which Sir Francis erected a few years afterwards for one of his tenants. How far Mr.

Meikle himself was indebted for his ultimate success to the sight and knowledge of Sir Francis' machines it is impossible to say. It is evident that approaches had been made by others to the principle which he was finally successful in carrying out, but none can deny him the high merit of being the first to construct a really serviceable machine. Sir Francis' efforts might have stimulated him; but it is well known that for years before, Mr. Meikle had made various attempts to construct a thrashing machine. There is a letter from six respectable farmers subjoined to the 2nd volume of *Wight's State of Scottish Husbandry*, published in 1778, describing a trial of one made by him on the principle of Mr. Menzie's machine, to which I have already alluded. His family possessed a hereditary right to genius and invention. It was his father, James Meikle, who went to Holland in 1710, in consequence of an agreement with the well known Fletcher of Salton. Meikle's object there was to learn the art of making pot barley, and also of erecting barley mills. He not only accomplished his design in a perfect manner, but after he returned, constructed the first fanners for winnowing grain that were ever seen in Scotland. However, to return to Andrew Meikle, he resolved to attempt thrashing by means of a rapidly revolving cylinder, with raised beaters parallel to its axis, standing out from its surface. This cylinder or drum was covered on the top by a concave surface, at some two or three inches distant from the circle described by the edges of these revolving beaters. A feeding board extended radially and horizontally outwards from the cylinder, and when near it terminated in two feeding-rollers, which revolving in towards one another, not only rapidly drew the straw forward, but held it from going too fast, which under the action of the beaters it would have been liable to do. The beaten straw, with the chaff and grain lying loose amongst it, was delivered on the floor behind the cylinder, and the operations of separation by fork, riddle, and fanners, were accomplished afterwards by hand. This is a description of the working model which he completed in 1785. It was driven by water, and first tried in that year at Knowe Mill, near Prestonkirk, a short distance from Houston Mill. It was found to do the work admirably, and completely answered his expectations. His son, George Meikle, being at Kilbegie, the residence of Mr. Stein, agreed to erect a machine, after the above-mentioned model, for that gentleman, upon condition of Mr. Stein furnishing all the materials and paying him for the work, "only in case the machine answered the desired purpose." This was agreed to, and the machine was completed in February 1786. It was found to work exceedingly well, and the only difference betwixt it and the original model was the substitution of fluted rollers for plain ones. Another was shortly thereafter erected for Mr. Selby, at Middleton, Northumberland. Mr. Meikle then applied for a patent, which, after some opposition, was granted in April 1788, for 14 years, and for England alone. Though Mr. Meikle obtained this patent he never acted on it, and when 10 years of it had expired, some of his friends stood forward and endeavoured to put it in force; but there was then such a number of erections by others that the design was abandoned. The late Sir John Sinclair, when President of the Board of Agriculture, strongly advocated Meikle's claims for a public reward as the inventor of the thrashing mill as then constructed. Through him and the Earl of Haddington a general meeting was held on 29th December, 1809, in the county town of Haddington, at which resolutions were unanimously passed, approving of Mr. Meikle's claims. A committee was formed, and subscriptions to the amount of £1500 obtained for behoof of Mr. Meikle and his family. After Meikle obtained his patent, thrashing machines were rapidly erected throughout Scotland and the north of England, with various improvements, such as mill fanners and rotating rake or rakes over circular frame-works for shakers. The invention of this shaker was claimed by Mr. Bailey of Chillingham, Northumberland. Much was done in the way of adding elevators and other improvements by a person in Kirkudbrightshire, but the machine itself and all the apparatus connected with it has continued almost until now in the same state that Meikle left it, for he readily seized and tried every alteration that occurred to himself or was suggested by others. Notwithstanding the total change of the moving power from sweating horses to the untiring and unvarying stroke of the steam-engine, the characteristics of a Scotch mill continue now in the same heavy drum, rotating rakes for shakers, and noisy wheels and pinions for putting the whole in motion. Dressing-fanners, in order to render the grain fit for the market, have been frequently added to the thrashing machine; but from the necessary irregularity in the quantity of grain thrashed per minute, and the difficulty of adjusting the fanners properly, complete success has been rarely attained. The best dressed grain I have ever seen done by machinery, and as thrashed on the beater principle, was on the farm of Mr. Hislop of Prestonpans. The grain as it came from the mill fanners was taken up by elevators, and then carried several feet by an Archimedean screw before it reached the dressing-fanners. This screw partly divides the grain and tends much to the delivery of a uniform quantity; again there are fixed across the hoppers of the fanners pieces of strong leather, which act like springs, opening when there is an additional quantity behind them, and contracting when the quantity diminishes. These simple but ingenious contrivances ensured, or very nearly so, the fanners having a steady and regular supply of grain at all times, and I believe it was mainly owing to this that the dressing was so perfect. When examining Mr. Hislop's barn machinery, I was particularly struck with the mode which he had adopted for carrying off the dust, and ventilating his barn. There was a large circular opening in the ridge of the roof, covered with a hood or cowl, which turned with the wind, the same in form and construction as those placed on the top of kilns for drying grain. The dust from the straw barn and chaff hole was conducted to it by means of thin boarding, enclosing a gradually narrowing space as it approached the aperture; of course, there was a large opening to it from the barn loft. It seemed to suit admirably, as the air was quite fresh and sweet, and on looking up to the hood out of doors, I was

astonished to see the dust flying from it like thick smoke. This is the first and only instance of which I am aware of anything having been done to promote the health and comfort of the work-people when engaged in this often most disagreeable, if not actually unhealthy employment. I consider it alike creditable to Mr. Hislop's head and heart, and I mention it here in hopes that he may soon have many imitators.

Before the application of steam power to the thrashing machine, it never was practicable to do more than blow the chaff from the grain, and even that very imperfectly accomplished. The first thrashing mill driven by steam in Scotland, or I believe anywhere else, belonged to the late Mr. Aitchison of Drumore. At the close of the last century, he had got a steam engine put up by Bolton and Watt at his distillery at Clements Wells. It occurred to him that as the steam engine could do the work of the distillery, there was nothing to prevent it driving the thrashing mill. He accordingly had it attached, at what exact period I cannot say, but it was certainly previous to 1803. However, he was so doubtful or afraid that something would happen to prevent its continued use, that he kept up the horse wheel attached to the mill for several years. I am not aware of any steam engines having been erected, solely for the purpose of thrashing corn, previous to 1818, when the late Mr. Sked, Dunbar, put up one at Westfield, near Haddington, for Mr. Archd. Dunlop. Either in that or the following year, Mr. Sked erected other two—one for my late friend Mr. Reid, Drem; the other at Linplum. Thereafter, condensing engines were speedily to be seen on all large farms where there was a sufficient supply of water. It is singular that the engine at Drem, after 40 years' use, should look as well, and be as efficient, as the day it was erected. In 1834 and 1835, high-pressure engines came into vogue. In a few years they multiplied rapidly; and now there is scarcely a farm of 100 acres in extent that has not got its steam engine. It is almost impossible to over-estimate the benefits we derive from steam power; at least, I am confident that no man who has ever been in possession of an engine, would again submit to see his horses toiling and straining in the weary course of a thrashing mill. I believe we have not yet taken full advantage of this wonderful power. It has been simply attached to machines contrived for horse labour, but it is eminently fitted for instruments of a far higher class. At the end of the last century, thrashing mills were considered by agriculturists as the great invention of the age. The saving of manual labour of a most laborious description, the more perfect and expeditious way in which the grain was separated from the straw, and the facilities they afforded for managing large farms, certainly entitled them to be so considered. But notwithstanding the great advantage we derive from the possession of steam power for propelling them, and the length of time that has elapsed since their first invention and general introduction, few will deny that there is a strong feeling of dissatisfaction at the way in which a great proportion of the machines in use perform their work. It seldom requires any great examination of the straw before it must be pronounced "rather imperfectly thrashed." If you shake up a quantity of the chaff, the chances are you find grain at the bottom. Is the straw barn empty, it will surely pay to sweep the corn from the floor for the sake of the pigs. And the rank vegetation often seen on the top of manure heaps demonstrates too clearly that we have in the end failed to reap the whole reward of our previous expenditure of time and money. Again, choked hoppers, overloaded fanners, and the barn in confusion, by a complete mixture of chaff and grain, are not such uncommon events, that any farmer would dream of losing his temper, or even of speaking a sharp word. These disagreeables and mischances are coolly set down as belonging to the nature of the machine. And when you hear complaints of the slowness of railway trains, and the stoppages at stations, we may be excused a little grudging and grumbling if, after two days' thrashing, it takes four days, as it usually does, to dress grain fit for market, and to clean up the barn. At this period of our history, and advance in mechanical science, we are surely entitled to look for something more expeditious and perfect.

Throughout the greater part of England matters have proceeded somewhat differently than in Scotland. From a supposed redundancy in the population, aggravated by the poor laws and the law of settlement, it is only within a recent period that thrashing machines have gained a footing there. In Mr. Boy's agricultural survey of Kent, published I believe at the close of last century, that gentleman states that his own thrashing mill was the only one in that flourishing county. He states; "I find there is a saving of nearly one-half of the expense of thrashing, besides the advantage of getting the corn out cleaner from the straw. There is, however, no small inconvenience attending so large a quantity of straw, chaff, &c., being got out at one time, when perhaps it is not wanted; and by that means it is either wasted or spoiled by neglect, before it comes to use." A commentator, in 1801, considered this disadvantage as imaginary, or at least easily obviated, "being convinced from *trial*, that if carefully and closely packed *at the instant*, straw receives no manner of damage from keeping, particularly if not much mangled or broken. But they who apprehend the contrary may secure themselves by cutting it into chaff forthwith, in which state we have Mr Young's authority that it will keep, undergoing a gentle fermentation. This process may be forwarded, by now and then throwing a little water on the heap, which, however, must be laid in a brick or stone building, having proper ventilation in the roof." Whether it was the failure of this plan of keeping the straw, or, as I suspect, the more potent reasons I have already mentioned, there can be no doubt that until lately thrashing machines never found much favour in the midland or Southern districts of England. In my first journey to the south I was astonished to find that the whole of the grain was thrashed by flails, on several large and otherwise well managed farms. I remember even in 1851, of a gentleman who farmed part of his own estate in Essex, showing me a small thrashing machine driven by a man, and which he looked upon as a very great improvement. A Scotchman has difficulty in comprehending this state of matters. However, the ma-

chines in use in England have risen from a broader origin, and exhibit much more diversity in their structure than the Scotch ones. It would be needless to go over all the improvements real or supposed that have from time to time been patented and brought before the public. I may mention shortly, that Mr. H. P. Lee, of Maidenhead Thicket, first introduced the principle of feeding without rollers, and his machine is supposed to contain the germ of the best English thrashing machines of the present day. The peg drum machine was invented by Mr. Aitkinson, of Masham in Yorkshire; it likewise has a high speed drum, but it has not obtained the success at first anticipated from it. Rubbing, bolting, or high speed drums have always in England been more in favour than those on the beater principle. For long the thrashing mills in general use there, have been carried about from one farm to another, and let out for a time to those who required them; they used to be only made for thrashing, and had seldom either circular rake or fanner attached, the want of which enabled them more easily to obtain the requisite speed for these drums. A few years ago they were all propelled by horses; but now steam, with improved machinery, which not only thrashes, but dresses, sacks, and weighs the corn ready for the market all at one operation, has completely banished these horse machines. Of course, men who make a livelihood by going about with thrashing machines are in a very different position from Scotch farmers, who consider it absolutely necessary to have a fixed machine on every farm. When the latter erect a mill, they expect it will serve their sons after them, and that it should thrash tolerably clean is all that has hitherto been expected from it. But a machine that is made to be let out goes at once to the wall, if another appears in the district with a single point of superiority. The introduction of portable steam engines gave the means of working a higher class of machinery, and the possessor of one improved machine compelled the purchase of many, which must have created a large demand, and accounts at once for the spring that has been lately made by the English makers, and the perfection to which their machines have so suddenly and recently attained. It was only in 1842 that the first portable thrashing machine on wheels driven by steam was made by Messrs Tuxford of Boston. The first combined thrashing machine was also brought out by them in 1844 for Mr. George Holland of Carrington; the combination consisting in this case of only one part besides the thrashing drum. They were speedily followed and improved on by other firms and makers; and doubtless Messrs. Tuxford's machines are now something very different, and their originals will long ago have been thrown aside as useless lumber. In 1854, Messrs. Clayton & Shuttleworth of Lincoln constructed portable machines, which dressed the corn twice at one operation, which was considered a great stretch, until in 1855 the machine was made to dress and finish it for market. In describing these improvements, I have no intention of singling out particular firms as being superior to others; in fact, I know too little of the construction that distinguishes the machines of many eminent makers, to be able to draw comparisons. But having been for a long time much dissatisfied with my thrashing machine, and thinking of having a new one, I paid some attention to the portable machines at the Royal English Agricultural Society's Show at Carlisle, and was much struck with their performances. Several of Clayton and Co's machines having been put up in Scotland, I took an early opportunity of inspecting the one obtained by my friend, Mr. Gulland, at Monktonhall. I was so pleased with it that I was resolved to have one of the same construction. Accordingly, Messrs Clayton, Shuttleworth & Co. fixed one for me last summer. It is driven by a six-horse engine, erected by Mr. Sked, in 1836. I have got a new boiler 18 feet long, and 3½ feet diameter; the old one, being barely 12 feet, was considered too small. I find I have abundance of power, and now consume considerably less coal than formerly. This machine gives me entire satisfaction. I have now thrashed nearly a whole year's crop with it, and we have never had any breakage or the slightest trouble with it, and it continues to go as smoothly and efficiently as the day it was started. It thrashes and dresses white corn equal to the average samples in Haddington market; beans come from it rough, but it thrashes them well, only requiring the concave below the drum to be thrown well back. I generally put the grain through the hand fanners previous to measuring it up, as this equalises the sample; and though previously well cleaned, every practical man knows that grain is well dressed indeed, if you cannot blow or riddle something out of it. I will now attempt to give you a short description of this machine. There are no feeding rollers, but the opening to the drum is rather below the centre of it, and the straw or grain is put in crossways, for it does not signify whether the heads come first or not, and they pass below the drum, in place of above it, as in the Scotch drum. This drum is styled Goucher's patent, with Clayton's improvements. Both it and the concave below it, through which a great part of the grain passes at once, are made of wrought iron. The drum is 4 ft. 6 in length, and 1 ft. 10 in diameter. It presents a rounded surface to the corn, grooved in an oblique direction; one arm is grooved obliquely from right to left, the next from left to right. The drum makes 1000 revolutions in a minute. The straw is thrown by its rapid motion at once on the shaker, which is termed Goods' Patent Shaker. It is divided into five boxes, three of which are on rocking arms at the receiving end, and two at the delivery end, which causes three at the delivery end to receive a jerking action, and two at the receiving end the same; the cranks being placed in the centre, cause an equal upright jerking movement throughout. As the one set of boxes ascends the other set descends, by which means the straw receives a succession of sharp blows, which effectually shakes out all loose grain. This succession of blows also carries forward the straw from the drum, and makes room for the succeeding portion. Except this shaker, which has boxes below it requiring to be filled with grease once a day, all the other bearings or parts requiring to be oiled are outside the machine. A great part of the corn falls at once through the concave on to a plain board, which extends also below the shakers. This board has a reciprocating action on an inclination, which carries

the corn, chaff, and cavings or short straw to the first riddle, which separates the corn and chaff from the cavings, and delivers the latter outside the machine; the chaff and corn fall on another inclined board, which carries them to the second riddle, and subjects them to the first blast, which takes out the greater part of the chaff. A second inclined board takes the grain to a third riddle, to take off anything larger than corn. The corn passes from the third riddle over an inclined screen (which takes out small seeds) on its way to an elevator. This elevator takes it up to the barley hummeller, where a spout admits of the grain being put into sacks, or passing on through the hummeller, which, by having the slides open, acts as a carrier; it may again be delivered into a sack, or it passes down, and the operations it received on the second and third riddles and blast are repeated, constituting the second blast, and fourth and fifth riddles. On leaving the fifth riddle, it reaches the second elevator, and is carried up and subjected to the third blast, where it can also be taken out as it passes on to the rotary screen, with Palmer's separator blades, which sizes the grain and finishes the operation. I may sum up, I am afraid, this rather vague description with repeating that the grain is five times riddled, thrice blasted, once screened, and once sized. As there are no toothed wheels in the machine, the whole being driven with belts and pulleys, it is not liable to breakage, and the chief noise is the loud hum of the drum, which sounds at a distance like a huge French top. It is extraordinary the quantity of work it will do, the difficulty being to get people to carry off the straw fast enough. It thrashes clean, and shakes the straw admirably; however, with very thick feeding, a small quantity of grain may be found under the straw-heck. Of course it requires some knowledge to set the concave properly in relation to the drum, to thrash clean, and at the same time not to injure the grain; with a little experience this is soon obtained by a workman of ordinary intelligence. The chaff is deposited at one end of the machine, and the straw at the other. This latter comes out so unbroken that it might almost be again tied up into sheaves. I think this a matter of some importance, even for littering cattle; it remains longer dry than broken straw, and it is incomparably superior for thatch. Before last harvest I was thrashing some wheat stacks at Fenton farm with an excellent Scotch mill put up 12 years ago, and I wished to make the straw into thatch; but it came out so broken as to be quite unfit for that purpose. I therefore drove the unthrashed grain to Fenton Barns, put it through the English mill, and sent the straw back tied up into excellent thatch. I had the Scotch mill completely overhauled at the same time last summer that the English mill was fixed, and having used both regularly since then, I thought it would be well to test the one against the other. The first trial was with wheat. Two carts were placed beside the stack, and sheaf about was regularly given to each; then other two carts were loaded in the same way, thus giving two loads to each machine. The carts having been previously weighed, were again weighed when loaded. The weight of the grain and straw sent to the English machine was found to be 30 cwt. 1 qr. 8 lb., and to the Scotch mill 29 cwt. 3 qr. 14 lb., making a difference of 44 lb. of additional grain and straw sent to the English mill. This latter produced of wheat, including best and light, 12 cwt. 14 lb. The Scotch mill gave only 11 cwt. 2 qr. 1 lb., being 69 lb. less. If 17 lb. are deducted for the extra weight of grain and straw in carts sent to the English mill, it will leave 52 lb. as the net gain on 1289 lb., or rather over 4 per cent. in its favour. The time taken to thrash these quantities was, by the English mill, 25 minutes, and by the Scotch mill 40 minutes. The straw that had been thrashed by the English mill was then put through the Scotch machine, and 10 lb. of wheat were obtained; and the straw from the Scotch machine, on going through the English one, produced 14 lb. The wheat was excellent quality, had been secured before the rain, and having been cut by a reaping-machine, there were few or no heads at the bottom of the sheaves, so that the circumstances were highly favourable for the Scotch machine. The next trial was with oats. When weighed, the oats from the English mill were found to be 43 lb. per bushel, while from the Scotch mill they were only 42¼ lb.; but there was an extraordinary discrepancy in the quantity in favour of the Scotch mill, which made me doubtful of its accuracy. At least it did not appear the grain was left in the straw, for on putting what came from the English mill through the Scotch one, literally nothing was got; while, when the straw from the Scotch mill was put through the English one, 12 lb. of oats were obtained. This experiment not having been conducted altogether under my own immediate superintendence, and the person who weighed the grain admitting it was probable he might have been mistaken with regard to the weights, I resolved to make another trial with oats. On this occasion the weight of the grain and straw thrashed by the English mill was 25 cwt. 18 lb., and by the Scotch 25 cwt. 84 lb., thus giving the latter 66 lb. of additional grain and straw, though I saw sheaf about given to each cart, which shows the necessity of weighing if perfect accuracy is required. The English mill produced 997 lb. of best oats, weighing 43¾ lb. per bushel, 81 lb. of grey, and 7 lb. of thirds. The Scotch mill produced 932½ lb. of best oats, weighing 42½ lb. per bushel, 95 lb. of grey, and 22 lb. of thirds—making altogether 1049½ lb. Thus the English mill produced 35½ lb. more corn, or 3½ per cent., and that without any allowance for the larger weight of straw and grain sent to the Scotch mill, or for what forms a most striking feature in the experiment, the greater value of the oats, from their being 1¼ lb. per bushel heavier, from having passed through the open hummeller in the English machine. The time taken by the English mill was 26 minutes, and by the Scotch one 47 minutes. The oats were the Sandy variety; they had been cut by the scythe, and though particularly tall and rank, they had been well handled, and no rakings were given to either machine, though to the English one it does not signify whether heads or tails go first. I attribute the great additional time taken by the Scotch mill to the extreme length of the straw. As every part of this experiment was done under my own eyes, I feel perfectly certain of its entire correctness. I have no hesitation in saying that before I made these experiments I preferred

the working of these high speed drums when propelled by steam. It was evident they did the work much quicker, and I felt sure it was also better done, which these trials have confirmed, and again, the straw being unbroken, was more useful for many purposes.

The people employed at the steam-engine and this thrashing mill are usually three men and nine women and boys. Two horses are also required for driving the grain from the stack to the barn.

	s.	d.
The men's wages may be reckoned at 2s. 6d. per day, or	7	6
9 women and boys at 1s.	9	0
2 horses	7	6
Coals, oil, &c.	6	0
	£1	10 0

Forty quarters of wheat may be counted a fair day's work at eight hours' thrashing; this makes the expense 9d. per qr., but exclusive of the interest of capital invested in buildings and machinery.

Machines are being put up by different English makers in various parts of Scotland, and in many instances the bolting drum is being substituted for the old Scotch beater. In my own neighbourhood this is very much the case; my neighbour, Mr. Bridges, of North Berwick, has already changed a considerable number. He does not consider they require more power, though an enlarged boiler is generally necessary, as they are more dependent for complete success on a high uniform rate of speed. In new machines Mr. Bridges also adopts the horizontal shaker, though, from its lifting only at one end, I should scarcely think it so efficient as that used by Messrs. Clayton, Shuttleworth, and Co. He has, however, ingeniously contrived to put three blasts into his mill fanners, to which the corn is subjected before being lifted by an elevator to the finishing fanners, which have two blasts. Thus, with only one elevator, the grain is exposed to five blasts, besides being put through or over five riddles and a shaking screen. I mention these facts to show what is doing, that Scotch engineers see the necessity of marching with the times, and that they are determined not to yield without a struggle to their southern rivals. But we Scotch farmers, nevertheless, owe a deep debt of gratitude to our English friends for the vast improvements they have already accomplished, and we may trust to be still more benefited by their wholesome influence. Viewing these English machines as portable ones, I consider them very near, if not altogether perfect. While I am more than pleased with my own new one, it would be too much to say that, as a fixture, it is unimprovable. The straw and chaff are deposited at opposite ends, which is better than having them together; but I would prefer a side delivery for the chaff; in fact, I have a strong leaning to the old Scotch plan of having the whole dressing apparatus set across the barn; it suits our buildings better. This new dressing apparatus does remarkably well, but it always appears to me too confined. You can only see the effect; you cannot see how it is done; and if any part requires attention, it takes some time to discover where the particular point is. I would prefer seeing the grain finished off by our old Scotch fanners, and desposited in them by Archimedian screws, carrying forward and regulating the feed, as Mr. Hislop has done. Again, from the general height of our buildings, it appears to me greater use might be made of the hopper or inclined plane, to run the grain to the blasts, without the intervention of reciprocating or other movements, which require to some extent an increase of power, besides extra attention and greater expense for wear and tear. But whether right or wrong in these remarks, which I offer with great diffidence, I believe you will all agree with me in thinking that the Highland Society has done well in offering an increased premium for thrashing machines to be exhibited at the Aberdeen Show, and I hope a still more handsome one will be allocated next year for the Edinburgh meeting. The rules which should be adopted in testing these machines require some consideration. I consider the first and greatest point to be clean thrashing, or the perfect separation of the grain from the straw. This can best be ascertained by the self-acting test of weighing quantities of similar straw and grain for each machine, and then weighing the produce. The second point I consider to be the state of the grain as it comes from the machine and the number of separations made in it. This test might also be made self-acting by passing each separation through a dressing machine, and ascertaining the proportion of tail corn left amongst the good, and also the good amongst the tail. The third point might be the unbroken state of the straw. The fourth, the simplicity of construction, strength, finish, and non-liability of the machine to get out of repair. Fifth, time required for the work in proportion to the power employed. Sixth, perceptible injury to the grain, or throwing it over amongst the straw, to be held as disqualifying points. If this meeting was to pronounce an opinion on these matters, it would confer a practical benefit on the Society, and also intending exhibitors, by allowing the former to have proper data to supply to the judges for their guidance, and the latter to know exactly what was wanted and expected from them.

We labour our land, we enrich it with manure often brought from the distant Pacific, we sow our seed, we reap and harvest our grain, and then too frequently throw a large percentage of it away. I trust the time is not far distant when improved thrashing machinery will be so common, as that every farmer in the land will have the satisfaction of knowing that no portion is lost of what costs so much.

The CHAIRMAN asked if any gentleman was prepared to offer any remarks on the paper that had been read.

Mr. SCOTT, Craiglockhart, stated, that having long ago been satisfied with the imperfections of the old Scoth thrashing machine, so ably described by Mr. Hope, he watched with interest the introduction of the English machines, and after careful inspection of the work performed at the English Society's Show at Carlisle, at our own Show at Glasgow, and of a machine he saw at the home-farm at Windsor, and having had a day's trial on his own farm of one of Clayton and Shuttleworth's machines, he formed the opinion that whilst the high speed open drum and horizontal shakers were greatly

superior to the Scotch drum and revolving shakers, that the Scotch dressing apparatus was fully as efficient as the English ones, while at the same time it was less complicated, and the working of the different parts more easily seen, and when anything might happen to go wrong, much more easily put to rights; and having a tolerably good machine with three sets of fanners, hummeller, and elevators, he resolved to endeavour to combine these with the English drum and shaker, for which purpose he applied to Messrs. Mollison and M'Vitie, of Earlston, to make the necessary alterations, which they have done by removing the old drum and shakers, and replacing them by a high-speed open drum with patent beaters, and Clayton and Shuttleworth's patent horizontal shakers. The result has been most satisfactory, and from the trials he has made with the different kinds of grain, he can with confidence recommend any person who is not inclined to put up a new machine to make a similar alteration. However, he thought it required more power to drive his thrashing machine than it did formerly, and he had observed that unless the drum be kept up to its proper speed, about 1,100 revolutions per minute, it did not thrash clean.

Sir J. M'Neill: I think it would be satisfactory if Mr. Hope or Mr. Scott could state whether the machine will do its work with horses. This is a matter of some moment in the more remote parts of the country. Does Mr. Scott think that the horse-power machines could be connected in the manner suggested by him?

Mr. Scott stated that he did not think it would be advisable to attempt to work those high-speed drums by horse-power, but thought either water or steam was more suitable as the motive power.

Mr. Finnie, Swanston, said that a farmer in his neighbourhood had twice an English machine, and from what he had heard, the machine did not answer.

Mr. Hope said he had received a letter from Sir John S. Forbes, calling attention to a machine patented by Mr. Isaac Harkless, suitable for a small farmer, whereby one horse could do the work.

Mr. Hall Maxwell: There is one point of great importance to which I may refer. It would be of great moment if any gentleman in the meeting could throw out suggestions in reference to the conditions that should attach to the trial of the machines in the show-yard at Aberdeen, such as were intimated by Mr. Hope. If such suggestions could be made, they might prove useful for the guidance of the gentlemen whose duties it will be to try the machines. I see Mr. Waller, machine maker, present—perhaps he could give his opinion.

Mr. Waller said the points that Mr. Hope alluded to in his paper had been freely canvassed in connection with the English Agricultural Society, and some difficulty had been felt there. The conditions had been left very much to the judges. He thought it very unfair to the maker that his machine should be subjected to a trial even by the most honourable men living, for this reason, that suppose two pieces of the very same quality of paper were taken—one blue and the other white—probably no two people would agree as to their respective value. It was merely a question of opinion, and it was much the same with agricultural machines. Again, in some cases the judges were all agriculturists, while makers were excluded. Now, the agriculturist told the maker what he required, and they tried to succeed to the best of their ability. In some recent cases they had certainly failed, and perhaps had done so with thrashing machines. Clean thrashing depended, he believed, more on the feeder than on the maker of the machine, and he thought that with a plain beater they could thrash as clean as with one of the improved beaters now in use, provided the drum were made suitable, and the beater in a proper state. The drum, as at present in use, was neither more nor less than the Scoth drum invented a hundred years ago, running at double the speed. The new power, instead of applying the old-fashioned drum, substituted an instrument specially adapted to man. Every animal had its greatest power in the direction of the spine, and the flail therefore was best suited to man. The horse worked, as it pulled, in the direction of its spine. The spine of the machine was rotary, and had a revolving power, and therefore the Scotch machine had a revolving drum and a revolving shaker. In the English machines they had gone back again to the horizontal movement with crank shakers. Now, with these shakers, there was a great waste of power, and of course an increased expense. He believed that a shaker crank, with ordinary work, could not work sixty days without repair. If the Scotch machines were put in competition with the English make, he did not think that the English would have a good chance, and the arrangements with regard to the awarding of the prizes would therefore require to be very seriously considered. He thought it would be better if the judges were not all agriculturists. In the English Society the judges were both machine makers and agriculturists.

Mr. Maxwell said that the same thing was done by the Highland Society.

Mr. Waller remarked that, in his opinion, it would also be necessary to come to some agreement as to the number of separations of the corn in the machine. He thought there ought to be four. This would require more power and more expense, but four separations of the grain could be effected as quickly as a fewer number. It was all one operation. It would be fair to the competitors to have everything stated.

Mr. Maxwell hoped that Mr. Waller would send his views in writing to the committee, who would consider the subject.

Mr. Maclagan expressed the pleasure he felt in listening to the interesting history of the thrashing machine given by Mr. Hope, his graphic description of the machine itself, and his statement of the inconvenience, annoyance, and loss to which farmers are subjected from ill-constructed machines. Having seen an admirably working machine erected in his neighbourhood by Clayton and Shuttleworth, and also the results of an experiment made between it and an ordinary Scotch one, he determined to test the efficiency of his own mill by comparing it also with an English one. He, therefore, engaged the machine made by Hornsby and Son, which gained this Society's premium in Glasgow. The experiment was made last autumn with a stack of wheat, of

crop 1856. Two carts were placed at the stack, and sheaf about was forked from it to the carts, which were driven and unloaded at the English and Scotch machines. The former thrashed at the rate of 5 qrs. per hour, including stoppages; and sometimes it was found to be thrashing at the rate of 7 qrs. per hour, when it was fed fast and equally. The Scotch machine had not all the modern improvements attached to it—the grain having to be put through the hand fanners once or twice after it had passed through the machine—which thrashed at the rate of 2½ qrs. per hour. The wheat experimented on yielded at the rate of 36 bushels per imperial acre. The results of this experiment have already been published; but as there are probably some present who have not seen it, and as it agrees so nearly with the results of Mr. Hope's experiments, with the permission of the meeting, I will give the details:

	Good Grain.			Weight per bushel.	Gross Weight of Good.		Light Grain.		Weight of good and light.	
	qr.	st.	lb	lb.	st.	lb	st.	lb.	st.	lb.
English machine	26	3	9	62½	128	9	4	10	133	5
Scotch machine	28	2	1	60¾	123	8	5	4	128	12

It is to be observed that the English machine gave both more good grain, and a greater weight per bushel, namely, 1¾ lb., and the sample was decidedly superior, both in appearance and in handling, and contained no broken grain. The results correspond very nearly with those obtained by Mr. Hope, being about 3½ per cent. in favour of the English machine. The good grain from both machines was sent to market, and sold by an agent on the same day; that from the English machine brought 5s. per qr. more than the grain from the Scotch. Wishing to know what became of the wheat that passed through the Scotch machine, he caused some of the straw from it to be put through the English machine, and after a quarter of an hour's working, he obtained 52 lb. of wheat. He also put some of the straw from the English machine through the Scotch one, and after five minutes work, obtained 1¾ lb. of wheat—that is, at the rate of 5¼ lb. in a quarter of an hour. Allusion has been made to the proper feeding of the mill. This is a most essential point; the feeder should have a good ear, he should know when he is feeding properly by the sound of the mill, and the master, though at a considerable distance from the offices, if he has a good ear will be able to tell if the mill is properly fed, simply by the sound which will be carried to him by the wind. A machine is often blamed for bad thrashing when the fault is altogether the feeder's. He was glad to hear Mr. Hope throw out some suggestions as to the elements of judgment to be taken into account in awarding the prize. This is most important; and there is one point in particular to which he would direct attention, namely, a fair and full trial of the machines entered for competition. Farmers will not be satisfied with the short trials in the show-yard, which may be kept up to amuse mere sight-seers, and thus help to swell the receipts at the gates. To show the importance of this subject he supposed that the whole of the wheat crop of 1856, in Scotland, had been thrashed by Scotch machines of equal efficiency to those used by Mr. Hope and him. By the agricultural statistics, 7,270,952 bushels of wheat were produced in 1856, which is equal to 908,869 qrs., and as 5s. per qr. more was obtained for the English thrashed than for the Scotch thrashed, there was a loss of £227,217 to the farmers of Scotland, from crop 1856, from using the latter instead of the former. It will be said that it was not all loss, as the pigs would get some of it; true, but there is no profit in giving to pigs, at present, food that is good for man; and slovenliness in one operation on the farm is sure to lead to slovenliness in others. This is no small sum, and it is no small matter for the Society to deal with. It has shown its anxiety in the subject by proposing this subject for discussion, and by offering a pretty large sum for the best thrashing machine, to be competed for in 1859; but whatever the expense, it must see that there be a fair and full trial of the machines when brought forward. It is rich, and is yearly laying past money; it has now a large sinking fund, and it can therefore well afford a good sum for carrying out an improvement so much desired as that of the thrashing machine. We must bear in mind that the usefulness and wealth of a Society such as this, is not shown by its always adding to its sinking fund, and by the amount of capital it has in the bank. Its usefulness and capital are rather shown in the zeal which it excites in its members, and in the improvements which are originated and carried out by its aid; and the interest of that capital is something far better and more lasting than mere money interest; it is the results of these improvements contributing to the prosperity of its members, the comfort of the community at large, and the permanent wealth of the country.

Sir JOHN M'NEILL: Was the grain you sold at market, sold to the same person, or to different parties?

Mr. MACLAGAN: The grain was sold in the same market, but I cannot say whether it was sold to the same person.

Mr. MAXWELL said there was every desire on the part of the directors to secure as fair a trial as possible, and they would neither spare time, trouble, nor money in endeavouring to obtain it. At the same time, he might allude to this little difficulty. The English makers, if they had their own way, would have no trial whatever. They said, "We don't want you to judge of the respective merits of our machines;" but the directors thought they were bound to take the best means of telling the people who came to the show, what in their opinion was the best machine. The directors had a duty to perform to the machine makers on the one hand, and to the public on the other; and they would take care that the trial should be the best that could be procured.

Sir JOHN M'NEILL hoped that the Scotch machine makers would not allow their English rivals to go a-head of them.

In answer to Mr. WALLER,

Mr. MACLAGAN said, he thought the drum of the machine used by him was what was called a peg drum.

Mr. SUTTIE thought the machines should be tried with different kinds of grain. A great deal, in his

opinion, depended on the style of feeding, and he hoped the judges would be very particular in selecting the feeder. If possible, they should have the same feeder for the whole of the mills. (Expressions of dissent.) Mr. Suttie went on to say that the English machines broke the straw, and that he had found a Scotch machine with peg drum thrash oats much cleaner than with the English machine.

A member wished to know if the peg drum would answer as well with steam as with horse power?

Mr. HOPE said, the right of patent was sold to various parties, and machines had been put up, but they were all taken down again in a few months. They did not answer when driven by steam. He did not know what was wrong.

Mr. WALLER said the peg drum was an American invention, and from the nature of its construction it must break the straw.

Mr. MACLAGAN: In the drum of the machine which I used the thrashing was performed by means of rubbing, and not by beating. There are rows of buttons on the drum, and also on the concave, which buttons rub against one another on the grain, exactly as if the grain was held in the hands and rubbed. The straw came out beautifully unbroken. It was so good that I thatched my stacks with it; after that I used it for thatching my turnip pits, besides using it for some other purposes.

No other member offering further observations,

Sir JOHN M'NEILL brought the discussion to a close by saying, that it was impossible for any one, whether connected with agriculture or not, to doubt of the importance of the subject to the welfare of the community, or to doubt of the excellent mode in which it had been brought before the Society by Mr. Hope.

A vote of thanks to Sir John terminated the proceedings.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Monthly Council was held on Wednesday, the 7th of April: present—Colonel Challoner, Trustee, in the Chair; Lord Walsingham, Lord Feversham, Hon. W. G. Cavendish, M.P., Sir Watkin W. Wynn, Bt., M.P., Sir Charles Gould Morgan, Bt., Sir John V. B. Johnstone, Bt., M.P., Sir Archibald Macdonald, Bt., Mr. Raymond Barker, Mr. Bramston, M.P., Mr. Brandreth, Mr. Caldwell, Mr. Druce, Mr. Brandreth Gibbs, Mr. Hamond, Mr. Fisher Hobbs, Mr. James Howard, Mr. Humberston (Mayor of Chester), Mr. Jonas, Mr. Lawrence, Mr. Milward, Mr. Paget, M.P., Mr. Pain, Colonel Towneley, Mr. Turner (Barton), Professor Voelcker, Mr. Vyner, and Mr. Jonas Webb.

The following new members were elected:—

Barrs, Thomas, Brompton Hall, Churchstoke, Salop.
Benington, Thomas, Wallingfen House, Brough, Yorkshire.
Case, Thomas, Testerton Hall, Fakenham, Norfolk.
Claridge, William, Pitchford Park, Salop.
Collings, Rev. William, Sark, Channel Islands.
Davies, Richard, Aylatone Hill, Hereford.
Ellison, Henry, Stone, Tickhill, Rotherham.
Evans, Edward, Boveney Court, Windsor.
Finch, Jacob, 1, Adelaide Place, London Bridge.
Gardner, Francis, Ryburgh, Fakenham, Norfolk.
Garsed, John, The Moorlands, Lantwit-Major, Cowbridge, Glamorganshire.
Grundy, Edward S., Reddish Hall, Lymm, Warrington.
Henry, Frederick, Lodge Park, Streffan, Scotland.
Horner, James, Lincoln.
Houblon, John Archer, Hallingbury Place, Bishops-Stortford.
Jackson, Robert, Corporation Road, Carlisle.
Johnson, J., Gunnersbury Park Farm, Ealing, Middlesex.
Johnson, J., junr., Hanger Hill Farm, Ealing.
Kettle, George Mackenzie, Dallicot House, Bridgenorth.
Lockhart, William, Hall Wood, Satton, Chester.
Mead, James, Penryn, Cornwall.
Menson, James, Brinsworthy, Northmolton, Devonshire.
Naylor, Richard Christopher, Hooton Hall, Chester.
Osbiston, Samuel, junr., Ryburgh, Fakenham, Norfolk.
Price, Joshua, Featherstone, Wolverhampton.
Richards, John, Mathgrafel, Meifod, Montgomeryshire.
Rigg, Rev. Arthur, The College, Chester.
Roscoe, Edward Henry, Newton House, Chester.
Sill, Rev. John Parkinson, Witheringsell Rectory, Stonham, Suffolk.
Stark, Michael John, Duke's Palace Bridge, Norwich.
Stobart, John Henry, Wilton-le-Wear, Darlington.
Strode, George Sidney, Newnham Park, Plympton, Devon.
Trench, William Stuart, Essex Castle, Carrickmacross, Ireland.
Tuley, Joseph, Truewell Hall, Keighley, Yorkshire.
Walker, Rev. T., Clipston Rectory, Northampton.
Walker, John, Newton Bank, Chester.
Weeding, Mrs., 47, Mecklenburgh Square, London.
Welsh, John, Kirkton, Hawick, Scotland.

FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented the monthly report on the accounts of the Society, from which it appeared that the current cash-balance in the hands of the bankers was £868.

HORSE-SHOEING.—Mr. Thompson, Chairman of the Journal Committee, reported the completion of a cheap reprint of the article in the last Journal on Horse-shoeing, by Mr. Miles, of Dixfield, near Exeter, of which members had the privilege of purchasing copies (at the office of the Society, 12, Hanover-square), at the rate of half-a-crown per dozen.

EDITORSHIP OF JOURNAL.—Mr. Jonas had leave to postpone his motion, "on the best course to pursue for the future editorship of the Journal," till the next Monthly Council.

LECTURES.—Colonel Challoner, at the previous Monthly Council, having called the attention of the meeting to the desirableness of having a lecture delivered before the members once in each month during the season, Mr. Fisher Hobbs moved, and Mr. Raymond Barker seconded, the following resolutions, which were carried unanimously:

1. That there shall be not less than four lectures during the season.
2. That Professor Voelcker, the Consulting-Chemist of the Society, be requested to deliver a lecture before the members in the Council-room of the Society, on Wednesday, April 28th, at half-past 12 o'clock, on "Agricultural Chemistry in its Relation to the Cultivation of Root Crops."
3. That the Journal Committee be requested to make ar-

rangements with the professors of the Society, for the ensuing lectures of the session; and to report the same to the Council at its next monthly meeting.

4. That each lecturer be required to furnish the Secretary, within one month from the date of delivery, with a copy of his lecture prepared for publication.
5. That a short-hand writer be engaged by the Society for the use of the lecturer, if required by him.

Prof. Voelcker, who was present, cheerfully acceded to the wishes of the Council, and engaged that the corrected copy of his lecture should be placed in the hands of the Secretary on the day after its delivery, ready for immediate publication. He considered that leading expositions of the agricultural questions of the day were best adapted for the purpose of lectures intended to be of a popular character; while the more matured discussion of results obtained in the laboratory, and their bearing on the principles and practice of agriculture, should be reserved for papers in the *Journal*, for which it was his intention that one at least should constantly be prepared and laid before the Journal Committee for publication in each successive number of the *Journal*.

THRASHING-MACHINES.—Colonel Challoner, as Chairman of the Implement Committee, reported that Messrs. Garrett and Sons, of Saxmundham, having inquired "for what machines prizes Nos. 6 and 7 (in the Society's Implement-sheet for the Chester Meeting) are offered, whether they are to be *simple* thrashing-machines, or *combined* machines having a straw-shaker, screen, or winnowing-apparatus attached, or one or more of these additions?" the Implement Committee had agreed to the following resolution, namely, "That the prize No. 6, for the best portable thrashing-machine for 6-horse power, is restricted to a simple thrashing-machine, having a straw-shaker; and that the instructions to the Judges would be in accordance with such resolution: That the machine for prize No. 7 would have a similar restriction, only would be worked by steam."

CHESTER MEETING.—The Hon. W. G. Cavendish, M.P., Vice-Chairman of the General Chester Committee, reported the favourable progress of the arrangements for the ensuing Chester Meeting in July. He made special reference to the plans under consideration for the best mode of exhibiting the very large amount of cheeses expected to compete for the local prizes in that department.

STEWARD-ELECT OF IMPLEMENTS.—On the motion of Sir Archibald Macdonald, Bart., seconded by the Hon. W. G. Cavendish, M.P., Mr. Cardwell, of Hilborowe Hall, was unanimously appointed steward-elect of implements at the Chester Meeting.

COUNTRY MEETING OF 1859.—Memorials and other documents received from cities and towns within the district of the country meeting for next year (comprised of the counties of Berks, Northampton, Oxford, and Warwick), were referred to an Inspection Committee, consisting of the Hon. W. G. Cavendish, M.P., Mr. Raymond Barker, Mr. Brandreth Gibbs, Mr. Fisher Hobbs, and Mr. Milward, with a request that they would visit the several localities to which the society had thus been invited, and report the result of their personal inspection to the Council at its next monthly meeting in May.

MEMBER OF COUNCIL.—On the motion of Mr. Fisher Hobbs, seconded by Mr. Milward, Mr. Huskinson, of Epperstone, Nottinghamshire, was unanimously elected a general member of Council, to supply the vacancy occasioned by the transfer of Mr. Thompson to the class of Trustees.

LABOURERS' COTTAGES.—Sir John William Lubbock, Bart., favoured the Council with the details of expenses incurred by him in the construction of a labourer's cottage in accordance with the plans of Mr. Isaac, of Bath, published in the Journal of the Society. This communication was referred to the Journal Committee, with a request for a special report.

Adjourned to April 14.

A WEEKLY COUNCIL was held on the 14th of April: present—Lord Berners, President, in the chair, Mr. Alcock, M.P., Mr. Raymond Barker, Mr. Foley, M.P., Mr. Fisher Hobbs, Rev. L. V. Harcourt, Mr. Thomas Scott, Mr. Vyner, and Mr. Burch Western.

M. C. B. von Neergaard addressed a letter from Denmark, announcing his invention of a drill-plough, which he desired to have exhibited, and if possible tried, at the Chester Meeting. Mr. Freer, of Rothley, applied for a further trial of his grain and seed-planting machine, exhibited at the Salisbury Meeting.

The Highland and Agricultural Society of Scotland presented copies of their premium-list of essays and reports for 1858 and 1859, and of stock, implements, &c., for their general show at Aberdeen at the end of August, 1858, and at Edinburgh in 1859. The Essex Agricultural Association transmitted the rules and schedule of prizes for their exhibition at Chelmsford, on the 15th of June next. Mr. Tanner presented a copy of his Prize Essay on the Cultivation of Dartmoor; the editor of the *Dublin Agricultural Review*, the first number of that new periodical; the Californian Agricultural Society, the Official Report of their fourth annual fair held at Stockton in the autumn of last year; the Normandy Association a copy of their *Annuaire;* the Algiers Society the 4th No. of their proceedings; the editors of the *Archives de l'Agriculture* of Lille and the *Revue Agricole* of Valenciennes, copies of their respective journals; M. de Gingins d'Eclepens (foreign juror from the Swiss Government at the Chelmsford Meeting), a copy of his Report addressed to the Swiss Federal Council, on the Chelmsford Show, and on English Agriculture; the Count de Gourcy, a copy of his agricultural *Pérégrinations;* and M. Rohart, a copy of his elaborate work on the Economical Manufacture of Manures.

The Council, having ordered their acknowledgments for the favour of these presents, decided, at the suggestion of the President, to recommend to the Monthly Council that the attention of the Journal Committee should be called to the foreign works recently presented to the Society, with the view of having such portions of them translated and published in the Journal as might

be considered likely to afford practical information to the English farmer.

Adjourned to April 21.

A WEEKLY COUNCIL was held April 21. Mr. Raymond Barker, V.P., in the chair; the Baron de Fircks, Mr. Caird, M.P., Mr. Druce, Mr. Foley, M.P., Mr. Fisher Hobbs, Mr. Majendie, Mr. Thomas Scott, and Mr. Burch Western.

NITRATE OF SODA.—Mr. Caird, M.P., laid before the Council the following correspondence between himself and the Foreign Office on the occurrence of Nitrate of Soda in South America:—

"Foreign Office, March, 27, 1858.

"SIR,—With reference to Mr. Hammond's letter to you of the 6th of January last, I am directed by the Earl of Malmesbury to transmit to you herewith a copy of a despatch from Mr. Morgan, her Majesty's Consul at Bahia, respecting the discovery of deposits of nitrate of soda.

"I am, sir, your most obedient humble servant,

"WM. SEYMOUR FITZGERALD."

"J. Caird, Esq, M.P."

(Copy.) "Bahia, February 18, 1858.

"MY LORD,—I have the honour to acknowledge the receipt of your Lordship's despatch No. 1 of January 7 last, instructing me to report, after a careful inquiry, on the localities in which nitrate of soda has been found in this province, its state of purity, the cost of extracting and refining it, and the expense of transport to a shipping port. In reply, I beg to state that ever since the mention made in my commercial report for the year 1856 of the discovery of this important manure in this province, I have received undoubted information of its existence in several other localities, and in consequence lost no time in renewing my exertions, with the assistance of a few friends having connections in the interior, to obtain every information possible thereon. The information received from several districts is such as to satisfy my most sanguine expectations, especially in the north-east of this province, in the neighbourhood of the river San Francisco, at a place called 'Salitre'—saltpetre (the generic name given to nitrate of soda, the use of which is unknown here). In the words of a most distinguished and talented native of the town of Joazeiro, on the St. Francisco, now one of the deputies of this province to the General Assembly of the Empire, the district of 'Salitre' is only seven leagues distant from the town of Joazeiro, and through a valley of sixteen to twenty leagues long, one mass of nitrate of soda is found; in some places on the surface, at others a few feet under; and contains sufficient manure for exportation for years to come. On the opposite side of the above-named river, near the town of 'Pilao-Arcado,' other deposits exist in equal quantities. Now the projected Bahia railroad to the town of Joazeiro must pass through the first-named district; but those magnificent deposits will only become available when that railroad reaches the St. Francisco. In the interest of the company and of commerce, it is ardently to be desired that its works should be commenced and prosecuted with vigour, as the distance is only 240 miles from this city. When I shall have received the replies to the queries I have forwarded to the several localities, I shall make up a report thereon for your lordship, and transmit at the same time the samples of nitrate I am equally promised. I have, &c. (Signed) "J. MORGAN."

On the motion of Mr. Fisher Hobbs, the thanks of the Council were addressed to Mr. Caird for the favour of this communication.

The following communications were also received:—1. From the Society of Arts, requesting co-operation in obtaining detailed information respecting the supply of Gutta Percha, and its employment in the manufacture of tubing for agricultural purposes. 2. From the Treasurer of the Massachusetts Agricultural Society, requesting information on the purchase of Ayrshire cattle. 3. A verbal statement by Baron de Fircks on manuring the black soil of the German provinces of Poland by burning the straw of the flax grown upon it, after the removal of the seeds. 4. From Mr. Wright, of Sigglesthorne Hall, a paper on the management of a herd of breeding cattle, with especial reference to the kind of diet, the treatment and condition best calculated to ensure regular fecundity and successful gestation, and on the causes which operate adversely in particular seasons. 5. From the Port Philip Farming Society in Australia, copies of their Transactions and Prize Sheets. These communications were referred to the Monthly Council and the Journal Committee.

Mr. Foley, M.P., laid on the table a statement of the great public inconvenience arising from different standards being employed in different districts for the purchase and sale of agricultural produce.

Adjourned to the 28th instant; when the Council would meet at 12, and Professor Voelcker deliver a lecture before the Members of the Society at half-past 12, "On Agricultural Chemistry, in relation to the cultivation of Root Crops," open to all Members of the Society.

MANURES, AND THEIR APPLICATION.

A PAPER READ BY MR. MITCHELL, BEFORE THE MEMBERS OF THE PENRITH FARMERS' CLUB.

DEC. 22, 1857.

The subject which I have been kindly requested to bring under your notice to-day, is one certainly not altogether of my own selection. Had it been so, had I been left entirely to my own choice, it is more than probable I should have called your attention to some topic or other of less importance; less vital in its consequences to our very existence as practical agriculturists; not that I think the subject unsuitable or unfit for discussion, but from the dread lest it should suffer damage in the hands of an unfit expounder.

The subject, as announced, "Manures, their adaptation, or proper and seasonable application to the soil," is one, and perhaps I may be allowed to say, the most important of all the subjects to which our attention as agriculturists can possibly be directed; because, holding as I do, and that most strongly, what from the increased and increasing value or

rental of farms, the increased though not increasing rate of labour, and the increased value of artificial manures, that unless proper attention is paid to the prudent and economical application, as well as liberal and generous allowance of manures to our fields and crops, it is in the very nature of things utterly impossible for the agricultural interest to keep (I neither mean nor say) *a-head* but *a-breast*, for that is our proper and natural position, with the commercial and manufacturing interests of this great country. Yes, sir, the time is gone by, when isolation can benefit any class; and certainly if anything were yet needed to dispel remaining class importance and bigoted imaginary independence, it is the sad, I had almost said the unparalleled money crisis, or ordeal through which our own country and other nations of the earth are at this moment passing. Talk, sir, of independence!—what can be the use of such a word, when England, the wealthiest country in the world, reels and staggers the moment brother Jonathan lives beyond his means, and thereby becomes unable to meet his just obligations? And if it be so with nations, so is it with individuals, professions, and classes, and so is it with agriculture. Agriculture can only thrive as such, when our mercantile and manufacturing interests are in a healthy state; in fact, they are mutual handmaids, or helpmeets for each other. And bearing this in view, I proceed, without further preface, to grapple with my allotted subject.

In doing so, I assume our lands are ready for the reception of manures; not ready, like the toil-worn horses, by over-taxation, work, and exhaustion, but ready from being laid dry and clean.

All of you, I presume, are practically, if not literally familiar with the sage saying, "Dry your lands, clean your lands, and feed your lands." By-the-bye, sir, you may remember being present at our last agricultural society's dinner, held in this very town. Our chairman, on that occasion, Mr. Crackanthorpe, claimed the authorship of that sagacious saying on the part of Lord Lonsdale. Had Mr. Crackanthorpe been conversant with the agricultural writers of Rome, he would have known that it was Cato, the famous old Roman, and not my Lord Lonsdale, who uttered those memorable words, so pregnant now with the experience of ages, "Dry your land, clean your land, and feed your land."

Assuming that all whom I now address are disciples of old Cato, and that all your lands are dry and clean, I proceed, not theoretically, but practically, to point to those manures, as also the season, manner, and crops, to which they should be applied, in order to ensure successful results. Of course, most of you are aware of the length of time to which my observations in this district of country extend; and therefore it is, I only expect, and ask you to pay that attention, which the facts to be stated, and the circumstances of the case, may seem to demand at your hands.

To proceed then, and at the very beginning I meet with difficulties, these difficulties arising, in part, if not altogether from the variety and number of manures now palmed upon the agriculturist, each claiming for itself to be the very panacea for all the wants to which our cereal and vegetable crops are subject. And the first of these, and perhaps the one upon which more than upon all the others put together, there is the greatest diversity of opinion as to whether it is a manure or not, is the farmer's time-honoured assistant—lime. Many, and some of them great authorities too, only assign lime a place in the apothecary's or druggist's shop. Now, sir, with all respect to these eminent authorities, I make bold to say, they have maintained, with fully as much dogmatism as practical common sense, that lime is simply a purgative or medicine.

Sir, I know not which may be the general opinion entertained by this Club, touching the ingredients which compose the most useful article in the manure table or shop of the sagacious farmer of olden times, nor am I at all anxious to open up what I fear might only lead to, and end in very unprofitable discussion. But assuming, if there is even one here who holds that lime is simply a purgative, and not a manure, even that one will admit, that waving the discussion (manure or medicine), lime is, at all events, a very large manure-producer. How, the question then is, and in what state should lime be applied? I presume, we are all at one in reference to the necessity of its being burnt, calcined, or in a caustic state. The question is, how long should it lie after removal from the kiln, and before its application to the land? And before we are in a condition satisfactorily to answer this question, we must ascertain what results are expected from its application, and to what it is to be applied. In a general way, we say, if it is to be applied to old grass land, that is, land never intended to be turned by the tearing plough, or at all events very remotely, then to all such, but to such alone, let it be completely fallen, dissolved, cooled: in fact, all but soured, before it is spread over, and in a quantity of not less than ten tons, and up to fourteen per acre. This quantity, the larger especially, is a liberal and generous allowance, in fact almost a complete covering to the land, and tends mightily to eradicate and waste away the old moss, which, whether it be from the extreme humidity of these two counties, Cumberland and Westmoreland, I know not, but certain is the fact, moss is most predominent in all our high pastures. And if this statement is borne out by observation, which I maintain it is, then certainly no small or inconsiderable advantage is gained; as I doubt not, the theoretical, as well as practical grazier, must have noticed the single-pointed grasses that find their way late in spring, through the dense hide or carpet of moss with which all our high, and, even in many cases, our low-lying pastures abound. Such pastures, lying in a state of nature, may be, and generally are stocked or stinted late in spring, or early in summer, with cattle. But what is the consequence? The poor animal is doomed to endless toil. He must rise early, and labour late to keep alive, to keep the skin and bones together, and then, when withdrawn at our ever-memorable Broughhill time, the owner or grazier finds the summer past, and his beast neither bigger nor better, and that although paying a stint price—hardly an acknowledgment for possession—he has actually been paying too dear for his whistle. But, on the other hand, wherever this class of land or pasture has had a liberal allowance of lime, in the manner described, there immediately, without any application

of seed, we get a carpet of choice white clover, not only keeping our cattle in good condition, but in many cases otherwise favourable, with shelter, &c., making them fit for the shambles, and besides keeping such extra numbers, the very droppings of which soon manure and quicken the pasture. Having, I hope, satisfactorily disposed of the liming of lands intended for perpetual pasturage, or, at all events, in such a way as to make myself understood, I proceed briefly to call your attention to the liming of lands under or intended for cultivation. To all such I recommend, and recommend strongly, the application of lime in the hottest possible state, and in quantities of from seven to ten tons per imperial acre. If the land has never been broken up, or has lain in green for any length of time, then let the application be made two or more years before breaking up, and considering the somewhat mountainous country where our lot is cast, the rains of winter and tempestuous winds of spring, with which we never fail to be visited, I would recommend the summer season as the best for having lime properly burned and applied. Rest assured there is too little attention paid by all of us in having lime in a proper state. At this season—I mean summer—there is scarcely any risk in having one side of the lime-kiln burnt to a cinder, the other cold and hard as the quarry from which it was excavated. Neither are the horses, carts, and harness, from frequent rains during the transit from the kiln to the field, so liable to be burnt; in short, less wear and tear every way. Of course, some may object to this season as being the very one when pasture may be said to be in the greatest luxuriance; this is not difficult to surmount. Either cut a hay crop and lime immediately afterwards, or if the field be unsuitable for hay, then withdraw all your cattle from your other fields, and eat over as close as possible, and long before the after-math from the hay, or the springing after the eatage is ready, to afford a full bite to the short-horn, the hot lime will have found its way to the roots of the grass, and be out of the way for injury to the tongues and teeth of the animals depasturing thereon. Some may suppose from the drought of the season, generally in summer, that a long time will elapse ere the lime falls or flours. No fears need be entertained on this score; the dews falling at this season are amply sufficient for the purpose: and be it remembered, there is no need for every piece of the lime to be completely fallen; twenty-four hours after spreading finishes the slaking. Lime applied in the extreme hot state, so far as my observation extends, does not kill and destroy old moss or fog, as it is sometimes termed, so quickly nor so effectually as when in a colder and soured state; still it finds its way quicker to the roots of the grass, and there, like an ever active agent, tenders or sears the sward, so that when the day and implement of destruction (the plough) arrives, the field lifts more like any tender new lea break, than the tough stubborn unmanageable soil we are accustomed to see where lime has not been applied; and besides, from the land harrowing more freely and thoroughly, the green crop is not only more abundant, but being equal in depth in the soil, springs at once, and shows a more uniform sample; in a word, altogether freer from greens and after-shots. Another advantage is gained, I think, by applying lime to old lea at least two years before breaking up, and that is, the saving of labour, when fallowing for turnips. The lime having lain two years, has the surface soil, as before stated, to a considerable degree tendered; then on ploughing the stubble an inch or two deeper than the lea furrow, the lime will be about central in the middle of the furrow, at work pulverizing the soil, and rendering it, as soon as the season for fallowing arrives, almost as soft and brittle as an ash pit, and saving reploughing, harrowing, grubbing, &c., a sum almost equal in value to half the cost price of the lime.

I must, however, bid adieu to lime, much as I value it, only, as it was my first love, I cannot do so without a parting benediction. Lime, then, I say, wherever practicable on your lea break, and in the summer season; yet such is my regard for it that I say, and say advisedly, rather than allow your farms to remain unlimed, lime by any means, any how, and at any season, betwixt Christmas and Lady Day, and Lady Day and Christmas.

I come now to speak of manure, on which there never has been any difference of opinion as to its being rightly and properly named or classified, and that is, old-fashioned farm-yard muck, and this, I take the liberty of saying, appears to me to be still the best of all mixtures. When I say so, let none suppose I underrate, or am ignorant of the value of the sanitary offals of our large towns and cities; these, I know experimentally, from their large admixture of night soil, &c., are, as fertilizers, all but invaluable; but then it is only in favoured situations—situations not subject to an expensive sea or land carriage—that they are available, and, therefore it is that I leave this valuable accessary to the farmer, out of my catalogue, as they are totally incomatable to a large number of the cultivators, situate within the mountain fastnesses of Cumberland and Westmoreland. To all then I say, especially, and to the farmers of Great Britain generally, that the farmer, be he who he may, who can produce the largest quantity of farm-yard manure in connection with the best quality, will very soon be found standing forth as the leading and most successful (other things being equal) agriculturist of his day and district. Now, there are various ways for doing this, that is, for swelling the manure heap, and also for increasing its value, and, I believe, there is none better, whilst, at the same time, I fear, none more overlooked and neglected by us all, than the properly securing the urine of our stalls and byers; this, in place of being conducted to some convenient receptacle, any one passing along our highways may have observed, in nine cases out of ten, finds its way to the horse pond or goose dub, rather than the manure manufactory. Now, in this, it is self-evident there is great waste, when buildings are not spouted round, for carrying off rain water; and landlords should be reminded this is expected from them, and being accomplished, then the occupying tenant must see that there are proper cesspools, or reservoirs, formed in some convenient place, into which he must deposit road-scrapings, chaff, dried peat moss, &c., at all convenient seasons, and then, into

and upon them the conduits from the byers and stables must play. After being thoroughly and completely saturated, say for a few weeks, then let the sluice or valve be uplifted (for I would have an outlet from the lowest level, same as a mill pond), for allowing the water to escape, and the mixture to dry; and so soon as removable in a cart, then away with it, either to the meadow or arable fields. Here, if anywhere, is the place for the water cart to be called into requisition. On lifting the sluice of the cesspool, the waste water might be distributed by the cart over the meadows or pasture fields. I am not, however, an advocate for the distributing cart—not because I lightly value urine as a top-dressing, but only because of the difficulty attending it, and the irregularity of its application. I am aware it is, and has been practised to a considerable extent on many farms; still, on the most of farms with which I am acquainted, it has been abandoned, for the reasons described. On the other hand, were it used by being absorbed in the cesspool, or compost heap, as recommended, there is scarcely a farm where there are not abundant materials for the absorption; only it must be remembered, as already stated, that rain water from the roofs of the houses, and the springs from below, are not to gain admittance to it; and were this carefully attended to, I question much if a world of unavailing deputations might not have been spared repairing to Her Majesty's government, for the purpose of urging them to use their influence with foreign powers to give us artificial manures, guano, and such like, at a cheaper rate. Another plan for swelling the manure heap, is by rotting under and around our animals a large portion of our straw. I am aware a very extensive practice prevails along these fell sides, of making all or nearly all the fodder of the farm pass through the intestines of the cattle. Of course there cannot be two opinions that this is the ready way for getting straw shortened and rotted, fit for application; but its being the best plan for getting quality, must not be so readily conceded. And most assuredly it is the worst of all for producing quantity. Of those who hold by the opinion that dung is best when all or nearly all passes through the intestines of the animal, I ask, What supported nature? Where came the beef, bones, and muscle from? It will be replied the animal had turnips, oilcake, or grain; granted; but if these improve manure with scarcely any straw or litter, they do it vastly more with it; and if none were given the animal fed on nothing but straw, then there cannot be a doubt that the animal has abstracted from the straw what supported nature, and to that extent, at least, reduced its value as a manure.

Perhaps, Mr. Chairman, it might afford a nice subject for discussion some day or other, when we are so much in lack of subjects, whether a ton of chopped straw, that is, a ton of straw fresh and direct from the chaff cutter, or a ton of straw eaten up by an animal allowed nothing but water, would be the most valuable to us as a manure. I might touch upon another mode for enriching manure, by the animal being fed on oilcake, &c.; but this I consider too expensive for general adoption.

Having pointed out the simplest and most efficient ways of increasing the quantity and improving the quality of farm-yard manure, I shall now, as briefly as possible, direct your attention to the best seasons for, and mode of its application. And, here again, I require to make a digression, or at least to ask a question. What sort of soil or class of land is the manure to be applied to? Is it land naturally inclined to produce straw in what (to be understood) I shall call over abundance? or is it the reverse? If the latter, that is, land stinted in the production of straw, then to all such apply the manure to the lea, immediately before breaking up for crop. Land of this description, I have always observed, when any plan or system could be devised—and I know of none and have practised none equal to the application of dung to the lea—for increasing the bulk of straw, always, and without any exception largely increased the quantity of grain. On the other hand, if the soil has a tendency to produce a large bulk of straw—the land I farm is of this description—then, upon no account must the manure be applied to the lea, but to the stubble, at the fall of the year, before giving the land the winter furrow.

At this season there is not the scorching sun, and rarely the withering winds we have about turnip-sowing time, so destructive to ammonia, the most valuable ingredient in dung; and besides, it is generally a period when the day labourer, women and boys, are in lack of employment; consequently, it will be a job for them to spread the manure, and afford us the satisfaction of conferring a favour, nay, a blessing, in an act that in reality costs us nothing, but rather the reverse, for by it we have a more equal distribution of hand labour on our farms over all the year, and thus liberate a large available force, at a very urgent and pressing season, for eradicating twitch and other filth, so unprofitable and so very discreditable to the agriculturists of the age.

Having given my opinion thus strongly in favour of autumn or winter as the season for the proper and economical application of manure, an objection may be started, or question raised, How are we to get it then? This is not difficult to meet, in accordance with a very common practice I have observed in this neighbourhood, and that is, the custom or habit of keeping a large portion of farm-yard manure over the year. This practice I certainly, and out-and-out, condemn; still, as it is a practice, it is better to turn it to a good account, by making it available for a start. I have said, I condemn the system of allowing manure to lie over the year. I do so on the principle that all vegetable substances exposed to atmospherical influence, and in a state of decomposition, become sadly lessened in quantity, and injured in quality, by allowing them to lie over, and thereby run to waste, or fly off in the air, what should be absorbed by and in the soil.

When, however, from any unforeseen or unavoidable cause dung has to lie over the year, then let it, if lifted from the trodden court at all, be carted out into a large heap, and the carts and horses when so engaged go right on to the top of the heap, so that it may be carefully pressed and prevented from decomposition; in this way dung may be preserved for a considerable time without much deterioration

or waste, and then turn it loosely up about three weeks before application. My opinion is, that dung is most rich and valuable when it is in a three fourths rotted state, that is, just before it loses the strong decaying heat, which it generally acquires about a fortnight or three weeks after lying loosely up. Some may say, 10 carts of completely rotted dung in a cold peaty state is much more valuable as a manure, and has more substance in it, than 10 carts in the condition in which I recommend it; this is conceded, but that is not the question. Are the 10 cold dormant decomposed equal in value to the 30, or, in many cases, 40, from which they were reduced? I trow not. Nay, I am thoroughly persuaded, from observation and experience, that storing dung over the year is most wasteful and imprudent.

My own system or practice, to have dung at command for the demands of my farm, and up to the extent of its ability in yielding or producing it (for, be it remembered, I am in a locality where none worth naming can be purchased), is to treasure up all that can be scraped together, say from the beginning of March to the beginning of June, for application to the meadow lands; then, my cattle—a considerable portion of them at all events – having access to a large open shed during the greater part of summer, which shed is well littered twice-a-week, makes a very large quantity of excellent rich manure. This is carted into a loose heap, out of the reach of the treading of the cattle, sometime about the beginning of harvest, or on wet days during harvest time, and is fully ready for application immediately after harvest, when I commence to plough my stubble. I have stated my land is not of the description to admit the application of dung to lea; consequently, as soon as all the available dung is laid on to the stubble and ploughed in, I drop ploughing stubble until I get more ready. Every month I clear out my loose cattle courts, mixing it loosely up with stubble and byre dung; and this, by lying a fortnight, then turning over, and allowing it to lie for another fortnight, is ready for use; consequently, a few acres of more stubble are got turned over, and so on continuously during the winter months, or until all the stubble is dunged.

I need scarcely remark, that placing the dung heap near the cesspool, and giving it a complete and frequent watering therefrom, adds very materially to the value of the manure. I have heard the practice objected to, of allowing cattle to get into courts during summer, as it is robbing the grass fields of their valuable droppings, and especially during hot weather, as then they are almost constantly in the courts, only taking a turn-out in the evenings and mornings, to eat, and immediately retire again under cover; and even, whilst parties don't go to the length of objecting, still they only admit it, when I talk of the valuable dung I make in this way, that I was robbing Peter to pay Paul. Now I grant I am doing so in a measure and to a limited extent; yet, if I can persuade Paul that he is as well off at a certain season of the year with 5s. in the pound as at another with 20s., Peter, I think, will have no cause to find fault with me when I present him with Paul's full discharge. Whilst, however, I advocate the application of dung in autumn and winter, let it not be imagined I advocate the sowing of turnips without anything in the stetch below them; no, far from this: this is the place and position for the artificials, bones, guano, &c., to occupy. In making up your stetches, make them equally deep as for dung; then either sow the artificial, whatever it be, broadcast or along the stetch; it is of no consequence which, as the resplitting of the stetch sends the manure to the centre and bottom, immediately underneath where the young seedlings are to be deposited. Of course, from its depth, it is out of the reach of the young plant for a time, but only for a very short time, and at a time too when not required, as the land having been so lately manured, either on the lea or stubble, is in a fine rich state by the thorough decomposition of the manure, and its complete incorporation of the soil; this immediately pushes forward the young plant into the rough leaf, and beyond the ravages of the fly, and as soon as it catches the rough leaf, its fangs may be assumed as clutching at the artificials.

If, however, farmers are averse to change the system of applying their farm-yard manure to the roots of the turnip, then there is certainly no natural necessity for their likewise clinging to the wasteful and slovenly habit I have observed followed, even by those from whom I should have expected other and better arrangements. The practice I allude to is that of stetching up, as is often the case, an entire field, then dunging the half or the whole of it, as the case may be, then spreading, or scaling it, as it is called, then resplitting the stetch, covering in the manure, and last of all, and after a day or two elapse, the turnip seed is sown. Now this practice or mode of procedure I cannot sufficiently condemn. In the first place, as is generally the case, the turnip sowing season is the one when we have the sun the hottest and most scorching; and in the second place, we have often withering spring winds, each of which are fitted almost to blast the expectation of the turnip striking altogether. In fact, I often wonder when I see the stetch seemingly made up for the purpose of withering any latent moisture that may be in the soil; then, again, when I see the dung first lying perhaps a few days in the heap, then when sufficiently dried, spread out along the stetch, to lie for a day or two longer, in order seemingly to perfect its destruction. Then comes the plough, as soon as both dung and land are so baked as to be impossible for covering up, and does its work: after which, and perhaps it may be a week, the seed is deposited, and then the slovenly and wasteful practice is ended.

The remedy I propose for this rude, primitive, and wasteful practice is just the one universally followed in every well-cultivated district, where the dung is applied in the stetches to the turnips. Whenever a field is ready for stetching up, then at whatever side of the field you mean to start, let twelve stetches be made for a beginning. It is always advisable to start at the side furthest from home, or from the manure heap, as by so doing there are no loaded or empty carts passing and repassing each other, and often treading and trampling the finished off and sown stetches. Twelve

stetches being set off, calculate your forces—so many carts for manure, so many women or boys for scaling, and so many ploughs for stetching in the manure, and a horse and a man for the seed drill, if your force will allow of it. As soon as the cart is filled with manure, let it be dragged out along the stetches, in quantity sufficient for three stetches at a time, and an active man will do this without ever stopping the horse. Then let the spreaders proceed in sets of three, each spreading their own stetch so many yards lengthwise; then another set, and so on, until all are at work, and always spreading backwards and forwards along their given quantity of yards, each set keeping by themselves. Then let the ploughs start—by the way, there is no necessity for double mould-board ploughs if this plan is adopted; the common one in daily use does the work much better, with only the small addition of an extra near-side plate attached to the plough, with two screw bolts for bringing the stetch to a narrow point at the top. I have said I prefer the single to the double mould-board plough; for this reason—the double plough works in the soil something like a wedge, and pushes all the hard, clotty, stubborn soil immediately underneath, where the young seeds are to be deposited; whereas the single plough cuts through, and throws up from the bottom of the furrow the moist and soft soil so necessary for the growth of the plant in its earlier stages. If the field lies upon a hanging bank, then let all the ploughs, following one another, each split a stetch over the hill, down bank. When at the bottom or end of the stetches, let all make another—a new stetch up the hill, or up-bank, as it is called—which will always leave the number of twelve stetches between, and ready for the cart and spreaders, without any risk of collision or causing them to interrupt each other. I have frequently had six ploughs following each other in this manner, always making six stetches the one way, and covering-in six the other, without any incommoding. A field going forward in this way, with large forces, has almost the resemblance of intricate machinery; and yet the very intricacy, every wheel performing its proper functions, keeps the whole in perfect harmony and working order. Be it observed, if this system is adopted, and properly and energetically carried out—ribbing *out* and *in* as it is termed in Scotland—a great advantage is gained in dry and scorching weather. A stetch is never lifted from the flat above half-an-hour until it is dunged, spread, resplit, and the seed deposited—in fact, all completed—which is a great advantage in any weather, particularly in a hot, dry, withering season.

It was remarked by a friend, when I consented to take up this subject, that I had made several experiments with manures, last season. I did so, and whilst I regret that the boisterons and ungenial autumn of that year prevented me testing them with the certainty of weight, yet the difference was so manifest to the eye, in favour of blood and bone manure, over ten other sorts, that I can have no difficulty in awarding to it the palm of victory. The kinds used were Peruvian guano, bone dust, bone meal, dissolved bones, concentrated manure, blood and bones, and various mixtures or combinations of the above.

One remark, and I have done, for I really confess my paper has extended to a most undue length—and that is, in reference to the manuring of meadows. I have already defined the period on an agricultural farm for making dung for meadow land—that I have shown to fall upon the spring months. Let the dung be exceedingly well prepared by repeated and re-repeated turnings and waterings, and if practicable, from the byres and stables, and also, if attainable, road scrapings, rich soil from any land end, or anywhere else, let it be mixed up with dung, as anything of that sort from its weight and attraction to the roots of grass, causes, in an almost incredibly short time, the growing in of the entire mass, and which early growing in is so essential for the succeeding crop.

Of course, speaking on this point. I do so with very considerable diffidence, for I honestly confess when I entered the sister-county a few short years ago, on this matter I had all my experience to collect and learn, and the result of that experience and observation leads me to point to autumn as the proper and beneficial season for application. Some practise, and recommend strongly, the application of dung immediately after cutting their hay crop; and I believe, in late and high lying districts, the arguments they adduce in support of what they practise, are difficult to overcome; still on the whole, looking at this county and Westmoreland generally, I am disposed to point to September or October, as the best season for applying manure to meadows: then the sun is shorn considerably of the force of his burning rays, the nights are getting longer, and in the absence of rain, for which, at this season, I believe few agriculturists pray, there are generally very heavy dews, and of course very considerable growth for speedy growing, in or over, as it is called. And in addition, by deferring laying on the manure until this season, a rich and valuable aftermath has been secured at a season of very great scarcity. But whatever be the season embraced for laying on the dung, never, if possible, let the sun set on a slovenly or unspread heap, either on meadow or arable field.

Thus, sir, have I brought at greater length than I could have wished, my observations on manures, and their application to the soil, to a close. In doing so, I am aware, on several points, I have ventured to find fault with and condemn the established custom and present usage of the district; this I admit should be at all times cautiously meddled with, by any one, more especially a comparative stranger; for often do we find, on further, deeper, and more searching investigation, the why and the wherefore it is so. Still, whilst admitting this, as little does it become those who have carefully collected experience and observation from the best-cultivated counties in Great Britain to stereotype any system that has nothing but custom and ancient usage to recommend it. At all events, I take the liberty, Mr. Chairman, of saying, with your permission, that I shall not be the man.

A TREATISE ON ROAD LEGISLATION AND MANAGEMENT.

By Richard Bayldon, Road Surveyor.

London: Longman and Co.

Roads are a fundamental provision for the convenience and improvement of any country, its traffic and the internal employments. The public highways that lead from one city to another, the roads of the parish, that afford access from hamlet to hamlet, the cartways of the farm, that give a passage to the fields, and from one division of land into another, the walks of the garden, that conduct to the various parts, have all been contrived for the same use, and with the same object in view, being spaces of ground ridden over, and trodden upon for purposes of public and private utility. Without these provisions of access, the value of distant parts cannot be realized, and the mutual benefit is denied, from which the social happiness of mankind derives the largest share of contribution. Without intercourse, human progress would remain stationary, and become a stagnation, having neither ripple nor movement.

The formation and maintenance of public highways have long been made a national concern, and have been subjected to legislative enactments. The cartways of the farm belong to the landowner and the farmer, and each parochial division manages the roads within its boundaries by a tax of money or work, and by officers for the special purpose. The great highways are placed under a wholly different jurisdiction. Being used for universal purposes, a tax is levied in the shape of tolls, on every passage over the road, which is applied, under commissioners and surveyors, to the first provision and to the future maintenance of the roads. As in many similar cases of legislative and financial applications, ignorance and carelessness have produced debts on the turnpike trusts, and the usual concomitant of a very inefficient condition of the roads as a public accommodation. Debt and inefficiency almost ever accompany each other, being the producer and the produced in a regular series of connexion.

For the purpose of removing and preventing both these evils of debt and inefficiency, we have now before us a treatise on road legislation and management, which in our opinion evinces no ordinary powers of practical discrimination, and original suggestions on the subject that is treated. A very extensive professional experience forms the ground work, which, along with a clear discernment and an enlightened judgment, constitutes the excellence of every progress that is attempted in any art or mixed science. In no art has it been more fully displayed than in the present treatise. The author's views on turnpike debts and payment of arrears are truly sensible and most highly honourable; he yields to none in wishing all debts to be extinguished, but requests time for the gradual liquidation, and the original rate of interest to be upheld. The terms proposed are fair and just, and strictly possible, as has been proved by trusts under his own care. An attentive perusal and consideration of this section of the work is most worthy of recommendation.

Twelve model clauses that are proposed to be introduced into all new turnpike road Acts, suggest the economical and proportional rates of charge on vehicles of carriage weight, of which the justice seems undeniable.

The author recommends the removal of toll-bars from the streets of towns and from the vicinity, thus avoiding the production of "Rebecca" feelings by an accumulation of bars and gates. The revenue required for the repairs of roads to be raised by a uniform rate, of a wide area, over the districts in which the bars are situated. This is a most sound policy over the present arbitrary divisions of townships or parishes.

The evils of letting road repairs by contract are briefly but clearly exhibited, lumping-sum contracts ever producing imperfect executions of work, although smaller specifications, that can be measured and minutely inspected, are let out, as work under contract, to do a certain quantity at fixed prices.

Our opinion most fully agrees that materials for repairs be laid on roads during the dry weather of summer, and not in winter as is usually done. In the latter case the materials sink into a soft bed that yields to the pressure; in dry weather the broken stones are placed on a dry bed, and set or cemented into a position by using a blending material, which is pressed together by a heavy roller, being first treated with a watering, if no showers fall to moisten and damp the mass. A pretty extensive experience with parish and farm roads gives a most unqualified assent to this practice.

The road-sweeping machine is used, and the saving over hand-labour to be applied in making dry and clean side-paths for travellers.

There are given in this work several tabular forms of accounts, most ingeniously contrived for practical use. The regulations and rules for workmen on roads, by the day or in contract, are very just and prudent, and prevent any quarrels or misunderstandings. A most useful table is given of the width and depth of road materials, of toll collectors, weekly returns, and district men's labour account, with an account of tolls received, and cost of repairs, other expenses, quantity of materials and depth, scraping expenses, the debts (increase and decrease), and the net amount. An explanation is given of the tables, with a notice of the statute duty due from parishes to turnpike trusts, in which a rate of money is charged on the rental.

Mr. Bayldon has displayed in a very full extent

the first, the second, and the third requisite of authorship—a thoroughly practical and judiciously enlightened knowledge of the business he engages to illustrate, with a modest and candid statement of views and recommendations. He has compiled a work that is equally useful to the commissioner of roads, the surveyor, contractor, toll-collector, and the labourer; each party will find a valuable something for their direction. This varied utility forms a high recommendation. And he has done very great credit to the relationship with the author of "Rents and Tillages," where sound practice and enlightened views have carried the work into seven editions with an unqualified approbation. The present work is a most worthy companion.

WAREHOUSING OF WHEAT.

Sir,—I lately observed some remarks in your excellent paper on the warehousing of wheat, which recalled to my recollection a plan I adopted, many years ago, with a cargo of 500 qrs. of wheat, which succeeded admirably. I will first state the reason for adopting the plan. I had seen numerous instances where wheat was put into granary, say, for one or two years, and, at the end of the time, I have found the wheat with a chamber smell, and full of weevils, and a loss of condition from three to five shillings per qr. The following would be something like the charges and loss on the old plan :

	£	s.	d.
2 years rent on 500 qrs, at 4d. per last..	85	18	8
Turning and feeing for 2 years	10	0	0
Loss in condition, 3s. per qr.	75	0	0
Loss in measure from weevils, &c., price £2 per qr.—one per cent.....	10	0	0
	£180	18	8

The loss of condition and the weevils is caused by exposure to the damp atmosphere of our uncertain climate which acts as follows:—The surface of the wheat imbibes moisture; then comes the warehouseman and gives it a turn, putting the damp below, and bringing up the dry grains to undergo the same process; and so a fine dry parcel is used, until the whole is lowered in condition, and rendered a very fit receptacle for all the moths that choose to fly in at the open windows, to deposit their eggs, &c. I determined to exclude damp and weevils at the same time by adopting the following plan: 500 qrs. of wheat was put into my hands to warehouse, probably for a long period, as the old corn law was in force. The management was left entirely to my discretion. 50 qrs. of the wheat was dried over a clear slow fire, and, when cool, carefully mixed with the bulk; the 50 qrs. was not dried for being damp, for the whole cargo was in excellent condition, and weighed 63 lbs. per bushel, but to enable the bulk to be laid above six feet thick. The windows were boarded, and carefully matted to exclude damp air and light. The wheat was then trimmed above 6 feet thick; the door of entrance, which opened into another store, was also matted up, and thus it remained for more than two years. I had it tried each year by a corn tryer, through slides in the floor above. When sold and measured up, I never saw a parcel of warehoused wheat that had kept so well, free from smell, and weevils; and, in measuring the bulk, all run freely to bushel. This cargo was shipped from this port to Havre, in France, and Messrs. Lafeette and Co. were so gratified with the condition of the wheat, they sent me a case of very superior claret as a present. The following was the entire cost incurred upon the wheat:

	£	s.	d.
Drying 50 qrs	1	5	0
Mixing and trimming the whole	1	0	0
The wheat laying thick, and not requiring turning, occupied less than half the usual floor, and a store was let by the year at £20. Two years.....	40	0	0
Matting windows and labour.....	0	10	0
Screening over when measured up.....	1	0	0
Loss in measure, 12 bush.	3	0	0
	£46	15	0

It is of the utmost importance to the agricultural interest that a safe system of storing corn should prevail. Capitalists would not then object to invest money in wheat, as they now do on account of the expence and loss in condition. Had I wheat now to warehouse, I think I could improve upon the plan. I shall be happy to reply to any inquiries that may be made upon this subject.

I am, sir, your obedient servant,

B. S. Sawden.

Budlington Quay, King-street.

GREEN CROPS FOR MANURE.

I am much gratified to notice the increased attention which is being accorded by farmers generally to this subject. Every one, in fact, who examines this subject attentively, must be speedily convinced of its utility, especially when turned in as an enrichment of exhausted soils. There is obviously no method by which the agriculturist can economise more, or more rapidly increase the fertility of the soil, than by turning in, as a dressing, such crops as derive a portion of their aliment from the air: no matter how impoverished or sterile the soil, he may, by a judicious and persistent pursuit of this means of amelioration, easily make it rich. There are many plants well-adapted to this purpose, among which are millet, buckwheat, peas, and clover, all of which are highly valuable, operating both mechanically and chemically, by their decomposition upon the soil, especially when containing much acid.

But it may not be improper here to remark that in making choice of crops to be turned in, we should invariably give preference to such as derive at least a portion of their pabulum from the air. The vegetables enumerated above are all of this class, and consequently take much less from the staple of the soil than those which are of course less adapted to this use. Of these, buckwheat and clover are perhaps the most valuable—the haulm being more vigorous, and at the same time much more succulent, and yielding much more readily to the laws of chemical affinity when inhumed beneath the soil. There is also another cause of preference, particularly in the case of buckwheat, the crisp nature of its stalk contributing greatly to the facility of turning it down, especially where the roller is used to precede the plough. On very poor land buckwheat may be grown with better success, perhaps, than any other grain crop, and will produce a more abundant yield both of haulm and grain. When sown to be turned in, unless the soil is calcareous to a degree rendering it unnecessary, the application of quick lime before turning in the wheat will be of great benefit. From two to three casks will ordinarily suffice for an acre; but if the ameliorating process is designed to prepare the land for the production of crops belonging to the order of lime plants, and which require a large amount of this mineral for their successful development, treble and even quad-

ruple the above quantity may be economically applied. It is not of essential consequence whether the application precedes the turning down of the crop, as is accorded subsequently, the principal object being to supply an important constitutional deficiency to the interests of the operator by limiting the agreeable product of the crop.

Clover is preferred by many to all other crops for this purpose, and, taking all things into consideration, it is, perhaps, not easy to say where preference should rest. The quantity of soluble matter contained in the clover plant, when arrived at the period of inflorescence, is unquestionably large—larger, probably, than in most other plants. Its roots, also, when mature, are large and succulent, and contribute very materially to the fertilizing effects of the crop when turned down at maturity; but it will be seen that where a speedy amelioration is required the plants do not commonly have time to attain their maximum development, and every one is aware that, in its youthful state, the clover plant contains a far larger quantity of fluid than of solid matter. Millet, if sown broadcast, will probably produce a greater quantity of readily soluble matters than either clover or buckwheat; but whether its fertilizing action upon the soil is so great is a question that remains to be decided: one thing, however, may be relied on as certain—any plant produced by the soil will, if turned in by the plough, contribute more or less to its enrichment. The families of the yuccas, and even the comparatively worthless cryptogamous vegetation, which is produced parasitically on rocks and in boggy swamps, have been ascertained to possess principles favourable to vegetable development, and when reduced by putrefaction, of aiding, very essentially, the phenomena of vegetable life. Nothing, in short, is worthless, in the great laboratory of nature; and it is there, over the crucible and alembic, that we receive these important lessons which so materially assist us in the numerous and multiform duties of practical life; here we discover the adaptation of means to ends, and become familiarized to the operative principles and laws with which we were before perfectly unacquainted and scarcely deemed to exist.—*Germantown Telegraph.*

LADY-DAY CORN AVERAGES.

Sir,—As at this period of the year it may be interesting both to your agricultural and general readers to know the average prices of wheat, barley, and oats in England and Wales for the 52 weeks ending on the 27th of March, 1858, I beg to annex the weekly averages from the *London Gazette*, and to state the result, which is as follows:—Wheat, 53s. 10d. per imperial qr.; barley, 39s. 11d. per imperial qr.; oats, 24s. 10¾d. per imperial qr.

In the annexed return it will be observed that the highest price of wheat was on the 17th of July, 1857—viz., 63s. 10d. per imperial qr.; and the lowest on the 26th of February, 1858—viz., 44s. 6d. per imperial qr.

The fluctuations in the price of wheat since the passing of the Corn Bill on the 26th of June 1846, may be seen in the following abstract:—

In the year ending	Average Price.	Highest Price.	Lowest Price.	Difference.

SUMMER AND WINTER TREATMENT OF CALVES.

In your excellent publication of date the 13th instant, "A Subscriber" complains that he has been losing his calves in a ten acre field of dry grass, with shelter sheds, "close to the north-east side of the cottage-houses, sixteen in number." Your correspondent states that, instead of growing like "mushrooms," as he expected, the calves in a few weeks commenced coughing, and went daily back, and that they appeared to die of a decline. You suggest to the "Subscriber" that the north-east exposure was the cause of the illness, aggravated by the smoke of the 16 houses.

Having had for twenty years considerable experience in the rearing of cross-bred calves, and having lately observed that several of your correspondents have put similar questions on this subject, I venture to address a few remarks to you.

The disease which your correspondent describes is evidently bronchitis. It is a most serious one, very common among calves before winter, most destructive to their condition, and in most cases fatal. A good many years ago I lost the half of my lot (40) from this disease, and in consequence my attention was drawn to the nature of the complaint, and the means of preventing it. I called in the aid of a veterinary surgeon (bred under Professor Dick), but he seemed to be able to throw little light upon the subject. We, however, tried all the ordinary cures that are recommended in books, and put setons into the necks of all the calves. I do not think that the north-east exposure would injure your correspondent's calves much if they were kept warm and dry through the night, and at all times protected from bad weather; nor do I think that the smoke of sixteen cottages in a ten-acre field would have any effect. In my own case I became convinced that exposing calves to wet and storm in the months of September and October was the cause of much bad health, and I have seldom found any coughing among those that were housed carefully at night at this period of the year, and not packed too closely, or allowed to lie on wet litter.

A man may put up shelter-sheds, but unless he takes care that the stock are *shut in*, he has no certainty that they remain in through the night and during rain. It is often a very difficult affair to get young stock into sheds early in the season; extra feeding will scarcely tempt them in; but even after they are used to it, they will frequently go into the shed and dance out again after having consumed their feed of turnips or cake. I have very often, after labouring, with the aid of several people, to get young stock into an open house at the darkening, visited them again at night, and found them lying down under the rain in the most exposed part of the field. This is easily accounted for. After eating their food they probably lie down for a while, and then wander out; a storm comes on, and rather than face it they fly from it, and at length find themselves at the end of the field farthest from the shed, where they probably remain till morning. I have known horses wintered in a field with an open house in it, that almost no power could get into the house, although some of them were old brood mares that had been stabled all their lives. I remember hearing of a gentleman of my acquaintance being complimented upon his shelter-sheds for young horses, whose reply was, "Yes, they are very well, but the devils won't go into them," and this has been exactly my own experience. Of course, after a long winter, storm and cold and hunger will force stock into such places; but early in the season, when the grass is green, young beasts will not go into open houses, and this is just the time when young calves lose their condition. Shelter-sheds to be of any use to young stock at this season require to be subdivided and protected by a wall or other fence at least half their length in front, with a hurdle upon the other half, to be shut at night or in bad weather. Young stock should never be put so closely together as to make their beds very damp from urine or the place too warm for their breath.

It is a difficult thing to carry calves well through the first half of the winter. From not being housed in time they are generally allowed to fall off a good deal between August and November, and they seldom recover fully till spring. The best way in my opinion to make good calves (next to letting them follow their mothers) is not to put them out at all the first summer, excepting for exercise, but to confine them to the houses and courts, where there is generally plenty of room when everything else is at grass. If they get plenty of cut grass besides their milk (and cake or meal if you please) they will thrive more rapidly than they would do in the field exposed to sun through the day and rain at night, and will lose nothing at the fall of the year.

Calves reared in this way never have coughs. Calves that are off their milk entirely before going out in June, if protected from the sun through the day (and in sunny weather they will go into shelter-sheds fast enough), often do very well at grass, and thrive rapidly; but as far as my experience goes, those which are drinking milk make bad grazers, and would be far better with cut grass in the courts. Calves are frequently allowed to lose much of their condition whilst learning to eat turnips; and condition, once lost with them, is not easily regained. The common way is to throw the turnips on the ground with the shaws on, and many weeks frequently pass before the weakest of the calves break them sufficiently; and all this time they are kept in a small space of ground, or shut into an open shed, and are supposed to be doing well because they are getting turnips, when in reality they are half-starved If turnips are cut with a sheep-cutting machine, or, what is better, pulped, and given in troughs, stock will eat them greedily in two or three days. The ten-acre field of your correspondent would be very useful as an exercise ground, either in summer or winter. It is not good for the calves' feet or joints to be confined always to soft litter, perhaps wet with urine; but I would not recommend them to be out in winter longer than three to four hours a-day, and this dependent on the state of the weather, and in summer the time of the day should be regulated by the heat of the sun. One very important thing to be attended to is to keep the sheds that the calves are confined in cool and dry, and of an even temperature. I believe that almost as much harm is done to young stock by allowing them to become too warm, as would be done by turning them out altogether.

These remarks are intended to apply to calves crossed from the Shorthorned bull. Galloway and Highland calves, being more hardy, can stand more exposure, and now-a-days the best of both these breeds are allowed to follow their mothers, with whom they remain late in the season, and thus become very strong and hardy. AGRICOLA.

ROOK FLIGHTS.—I have frequently been very much amused by the conduct of a colony of rooks in the fine elms of our meadow, a few years ago; for I am sorry to say that decay has begun among the trees, and, true to their instincts, the rooks have now nearly deserted their old haunt. When the rookery mustered about fifty pair of birds, the music was in full chorus, and, generally, one or two birds whether from catching a cold or not, I cannot tell, but their voices would break into falsetto, contrasting very prettily with the general harmony of thirds, fifths, and octaves blended together. A very curious custom was followed by these birds in the latter end of autumn and winter. The rookery was only used as a breeding place, and the roosting trees were situated about two miles away, where several colonies would congregate to pass the night. In the morning the whole of the birds betook themselves to their regular feeding grounds and a considerable muster passed over the Maidstone rookery, perhaps two hundred of them. The Maidstone birds would then separate from the grand flight, and drop down to the old familiar spot, where they held a very ani-

mated discussion upon some subject unknown to me. In about fifteen or twenty minutes, all would proceed to their feeding grounds with business regularity. In the afternoon if food had been plentiful) an evening visit would take pace; but this was differently conducted, for all sat solemnly perched, and no cawing, nor any disturbance, was allowed This was a Quaker meeting; and after a short time spent in a quiet orderly manner, a gradual dispersion took place in twos and threes, and, before dark, they had joined the metropolis, where would be heard a grand burst of cawing as every detachment arrived. I fully believe that questions were asked and replies given; but I doubt if we shall ever master the rook-tongue. Perhaps a Chinese might make out some of it, but then the grand difficulty would be to understand John Chinaman.—Correspondent of the *Family Friend.*

FOOT ROT IN SHEEP.

This disease is, I believe, but little understood by farmers generally, except those who have been brought up on flock farms, and have made the nature and diseases of these animals their special study, and foot-lameness arising from over-driving, or wetness of pastures, is often mistaken for it. The real foot rot, which is a terrible complaint if you once get it among your flock, is easily detected by a peculiar smell arising from the diseased feet that does not attach itself to the common foot-lameness, although I have no doubt if neglected, that complaint will ultimately resolve itself in the foot rot. The stench arising from the parts affected is so unlike any other that if you once smell it you will never after mistake it, but can no more be described than a Yankee hunter can describe the stink of a skunk. Foot-lameness frequently causes discharge, but not of that fœtid nature that characterises the real disease, and may generally be cured by simple remedies; but if you detect in the discharge an indescribable fœtid smell, depend on it you have got the foot rot among your sheep, and in that case put them on your dryest pastures, or if possible under cover, and feed and fat as fast as you can; but by no means allow sound sheep to come upon the land tainted by the diseased ewes for some time, or the complaint will arise again among your fresh flock, and especially upon wet soils, which seem to retain the power of inoculation much longer than dry ones. It is a difficult thing to get rid of a diseased flock, except by fattiug; and it is a very dangerous experiment to sell them to a feeder if you have the slightest symptoms of it among them; but if they were thoroughly diseased it is equally difficult to fat them well; and then, after having found that simple remedies do not check the disease, I should advise the adoption of the following measures, which I have known successful when all else have failed. Let your shepherd examine the sheep singly, and, after cleansing the diseased foot thoroughly, drop on the affected parts one or two drops (not more) of butter of antimony. In two or three days again examine them, and take a small quantity of blue vitriol, and add it to a pint of white vinegar, varying the strength of the dilution according to the violence of the disease, and dress the foot slightly with this mixture. You will soon see that the sheep improves in appearance, it treads more soundly, and the eye gets brighter, having a more fresh appearance altogether. And then with the following ointment—Take of lard and soft soap half-a-pound of each, and simmer gently over a slack fire; add 2 oz. of rosin while it is cooling, and when nearly cool simmer again, adding, while simmering, a quarter of a pint of green oil; while it cools, put in a small bottle of balsam from the chemists, and stir the whole until it is thoroughly mixed. This plan, although tedious, will cure your sheep, but do not trust them again or breed from the ewes; fat them off at once, and get a fresh flock. The ointment is extremely useful to keep by you during the lambing season, as, after straining, it allays inflammation by application to the parts, and in difficult cases facilitates the getting away of the lamb. A FARMER.

CALENDAR OF AGRICULTURE.

The planting of beet and potatoes must now be quickly finished, if any remain undone from last month. Horse and hand-hoe all drilled crops: allow not a single weed to be seen.

Turn over the heaps of winter-prepared dung; and fermentation will readily commence. During its progress, lay the dung in drills. Reverse the ridglets, and sow the seeds of Swedish turnips immediately, which will derive much benefit from the near contact with the fermenting dung. In the first place sow common swedes, then Laing's and Matson's Hybrids, and follow with Aberdeen Yellows. In dry weather, roll the drills immediately: in moist, showery weather, it may not be required.

Plant cabbages, kohl-rabi, savoys, and winter broccolis from the seed-beds, on drills three feet apart, and the sets two feet asunder along the drills. Apply very moist half-rotted dung in a large quantity on strong clay loams, and dibble the plants into the ground during the wettest weather in which work can be performed, as the plants require much moisture. Fill up blanks with fresh plants, in order to procure an even crop. Sow early turnips for an early crop, as Tankards and whites; and sow rape, to be consumed on the ground, as preparatory for wheat.

Pare and burn rough lands, and spread the ashes, in order to cool their warm condition. Prepare the fallows for green crops, and also clay fallows for wheat.

Stall-fed cattle will now be disposed of—the fat animals to the butchers: the leaner will go to the pasture-fields, to be fattened on grass; but the milch cows to pasture of permanent grass, adjacent and convenient, provided with water and shelter, and improved by frequent top-dressings and the sowing of clovers and of strong perennial grasses. But a rich natural quality will not require any assistance. The oldest calves may go to the grass paddock; and if the grass be scanty, assistance must be given in racks, with clovers and vetches. A shelter-shed and a supply of fresh water are indispensable.

The latest lambs will now require much attention, and must have the best pasture on the farm,

in order to raise an equality with the foremost. The equal condition of animals, as well as the breeding, shows the proper management of animals.

The ewes and lambs that are eating vetches and rye must have fresh food every two days. Begin the soiling of horses and cattle in the yards. The milch cows will need assistance in green food, if the pasture be scanty. Feed the store pigs with clovers and vetches; and afford ample littering to all animals. As the early soiling green crops are consumed, plough the land for turnips.

Put mares to the stallion, and get colts; though this operation may be more safely performed the previous autumn.

Finish the sowing of grass-seeds on the barley-tilths. Sow by machine, and cover with light harrowing and a heavy rolling.

Dig hop-plantations, and tie the bine to the poles. Shut up watered meadows for hay.

Wash sheep by hand in a clear running stream; and, for preventing the maggot-fly, sprinkle the animals from head to tail, from a dredging-box, with a mixture of hellebore-root powder and of black brimstone—¼lb. to 1½lb.

Weed young quicks. Set thorns in hedges, but not to expose the roots quite bare to the sun's rays in dry situations. Rather leave the weeds to moisten the roots, provided the upward growth be not checked.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

BLAIRGOWRIE FORTNIGHTLY MARKET was well attended, but business was dull. There were 124 cattle on the ground, the best of which sold at from 6s. 9d. to 8s. per stone. Milch cows were on demand, and sold readily at from £6 10s. to £12 10s.

CHESTER FAIR.—The supply of milking cows and young stock was large, but not a fat beast was to be seen. The prices for sheep and barrens were a shade higher. In the horse fair there were some good animals, but the business was not brisk.

CORWEN FAIR was very well attended by buyers. A great number of cattle was exhibited, and there was a better demand for barrens than for any others, their prices varying from £9 to £11. Few horses were shown, and those not being of the best qualities, but a small business transacted. Store pigs were lower than usual; sucklings from eight to ten weeks old, from 7s. to 10s.

DEVIZES FAIR was very largely supplied, sheep only being an average number, about 5,000 having been penned. The sheep, which were mostly tegs, sold at from 30s. to 36s. each; and couples at from 42s. to 48s.; the trade being rather better than at late fairs. There were a few fat sheep, shorn, sold at 6d. to 7d. per lb. The supply of heifers and calves was very large; trade was dull, and prices 25s. to 30s. a-head lower, from £15 to £20 being about the range. Beef sold at from 10s. to 11s. a score. Horses were numerous, and of all qualities, except the best.

DULOE FAIR.—There was a good supply of well-fed cattle, which found a ready sale at £3 per cwt. for beef, and 7¼d. per lb. for mutton. The fair being remarkably brisk there was a good amount of business done.

EAST GRINSTEAD FAIR.—Business was brisk in horned stock. Yearlings and two-yearlings were in demand, and there was an improvement in prices. Fat stock was not so, and rather hung in hand; sheep were sought after, particularly good Downs, but the samples of sheep at the fair were not of that character. There was a short supply of good cart colts. Pigs were not so numerous as usual, and prices were rather lower. On the whole there was a good share of business transacted, and trade was brisk.

FENNY STRATFORD FAIR was the largest we have seen for many years. A great number of cattle, sheep, and pigs were on sale, most of which changed hands.

GLOUCESTER MONTHLY MARKET was well supplied with every description of stock. The beef trade ruled heavy, and the number of sheep penned was fully equal to the demand. Beef, 6d. to 6½d.; mutton, in the wool, from 7d. to 7½d.; shorn sheep, 6d. to 6½d. per lb.

LINCOLN FAIR, as far as business is concerned, shows a decided falling off. Up to Wednesday night less money had changed hands than had been known for many years. The attendance of horse dealers this year has been very large, including all the principal English and continental buyers. France was largely represented—far more so than during the Crimean war, and this may be taken as an indication of the high estimation in which English horses are held among the French breeders. The business on Monday was confined to first-class animals, which, however, were by no means readily to be met with. Second and third-rate hackneys and carriage horses were a drug, dealers refusing to comply with anything like the demands of sellers. The business was throughout the day extremely slow. On Tuesday, owners of second-rate horses still refused to accept the prices offered by buyers, and the business effected was limited. On Wednesday there was a very large show of horses, the unsold ones and the new arrivals, which consisted chiefly of cart and farm horses, making the supply far more than equal to the demand. As the day progressed, a little more life in the trade was manifested, and several good hack horses changed hands at prices ranging from £30 to £50. All but the very best hung heavily, and prices for all descriptions must be quoted fully 20 per cent below the prices of last year. The sheep fair on Thursday was a very large one: at least 60,000 were penned. The average quality was decidedly good, far better than could have been expected, considering the long dry season and the scarcity of keeping. In the early part of the fair, prices ranging from £2 to £2 16s. per head were demanded, the high prices of last year evidently being very prominent in the recollection of sellers; but prime wether hogs of the same description which last year commanded prices as high as 70s. per head, could not be sold at a reduction of 30 per cent. The business done, however, was very limited, and nearly half the pens remained unsold at a late hour. The current prices for good useful hogs were 40s. to 45s. Mr. Howard, of Dunholme, sold a pen of splendid hogs for 56s. a head. There was a good show of fat sheep, which sold at a slight decline on the prices of last market day, the extremely hot weather causing the butchers to purchase with caution. A few lamb-hogs were in the market, but the high prices asked were not paid. As a whole, the fair must be pronounced the dullest known for many years past.

SHIPSTON-ON-STOUR FAIR was well supported, but trade was dull, owing to the great reduction in the value of first-rate horses; prices varied from £25 to £60. There was also a good supply of sheep and cows; beef realized 6d. to 6½d.; mutton, shorn, 5½d. to 6d. Some pens of sheep, sold by auction by Messrs. Bull and Son, the property of Mr. Sheldon, of Brailes, realized 69s. a-head.

SOMERTON FAIR was not so large as usual, and prices generally ruled dull. Fat beef from 9s. 6d. to 10s. 6d. per score; fat sheep, 6d. to 7d. per lb.; cows and calves,

£11 to £15. There was a large quantity of pigs penned, and lower prices than of late had to be submitted to, to effect sales.

TENBURY FAIR was well supplied with stock. There was a good attendance of butchers and dealers, and rather better prices were realized than at recent fairs. Beef averaged fully 6d. per lb. Barren cows were dear, and cows and calves made satisfactory rates. There were not any fat sheep on offer, but good couples met with purchasers.

TEWKESBURY FAIR was well supported, but the greater part of the business was transacted through the hands of the auctioneers. Messrs. Weaver and Moore sold upwards of 560 beasts, and Messrs. P. Thomas and Son also sold a large supply of stock. Beef sold at from 5d. to 6d.; mutton in the wool, from 6½d. to 7d.; shorn, 5½d. to 6½d. per lb.

TIVERTON GREAT MARKET.—The brilliant weather did not appear to operate as an inducement to graziers to send their cattle to market. The number of bullocks driven was hardly equal to an average. Owing to the small supply and the extensive demand, beasts of good quality went off freely. The prices obtained were, however, rather below those which were realized some time since. Fat bullocks were not plentiful, and sold readily at from 9s. 6d. to 10s. 6d. per score. There was a tolerable show of cows and calves, which fetched from £12 to £17 a-piece. Barrenors were worth 7s. per score. The few working steers exhibited were quoted at £36 per pair. There were not a great many sheep penned. They were disposed of at remunerative rates. Fat wethers 7d., fat ewes 6d. to 6½d. per lb.; store hogs 35s. each; butchers' calves 5d. to 6d. per lb.; rearing calves £1 5s. to £2 each.

TOWYN FAIR.—The attendance was far more numerous than was anticipated, as in consequence of the delightful weather the farmers were busily engaged sowing. The supply of stock was not large. Two-year-old steers realized from £7 to £8; cows, in-calf, from £12 to £14. The supply of horses was very meagre; some entire animals were exhibited, and appeared very strong and useful.

WINSLOW FAIR.—A good supply of beasts, sheep, and swine, and a numerous attendance of graziers and dealers. The cow stock was remarkably good, especially the heifers, some of which made from £18 to £20 each, but the trade was generally speaking dull; pigs a slow sale, at moderate prices; a poor supply of horses.

WALES CATTLE FAIRS have been held at Carmarthen on the 15th, at Langathen on the 16th, and at Landovery on the 17th of this month. There was a fair number of store cattle for sale at each of those places. There was a full attendance of dealers, and nearly the whole of the stock were sold at about ten per cent. lower than at the same fairs this time last year. Cows with calves were rather scarce and commanded high prices. Fat cows were in fair supply and demand at fully late rates. Horses and colts were rather scarce and in fair demand, but at low prices. Pigs continued in good demand at no improvement in their value.

WORCESTER FAIR.—There was a large supply of beef, and many fat oxen were sold by auction. Beef made about 6d. per lb. Sheep were also plentiful. Fat mutton, out of the wool, brought about 6¼d., in the wool 7¼d. to 7½d., and considerable business was done in this department. The show of store cattle was limited, and the demand was tolerably brisk, at improving figures. Store sheep were more plentiful, and sold well.

CHESTER.—There was an abundant supply of cheese for the time of year. Plenty of factors were present, and purchased freely anything that was good. Prices ranged from 45s. to 62s. The quantity pitched was nearly 130 tons. Several lots were taken home, and some remained unsold.

GLASGOW.—There was a large supply of cheese, and a very heavy market. Eight carts were shown in the bazaar, and 19 tons passed the weigh-house scales. To make sales, lower prices were taken, although we continue former quotations: Prime early made, 49s. to 52s.; inferior and late made, 44s. to 48s.; new skim, 24s. to 25s.

HOP MARKET.

BOROUGH, MONDAY, April 26.—Our market maintains the same steady character as of late, most descriptions being in moderate request, at the following quotations.

Mid and East Kents....	70s. to 90s.,	choice	112s.
Weald of Kent.....	54s. to 60s.,	"	66s.
Sussex	50s. to 54s.,	"	60s.
Yearlings, &c.	21s. to 35s.,	"	50s.

POTATO MARKETS.

SOUTHWARK, WATERSIDE, MONDAY, April 26.—Since our last report the arrivals have not been heavy, either coastwise or from foreign ports, but the trade has been in so languid a state that there has been no opportunity of effecting sales; so that our quotations are almost nominal, as follows—

Yorkshire Regents.....	140s. to 180s.	per ton.
Lincolnshire do.....	140s. to 160s.	"
Dunbar do.....	140s. to 180s.	"
Do. reds	80s. to —s.	"
Perth, Fife, and Forfar Regents	120s. to 140s.	"
Ditto ditto reds	70s. to 80s.	"
French whites	40s. to 80s.	"
Belgian do.....	50s. to 60s.	"
Ditto reds	80s. to 90s	"

BOROUGH AND SPITALFIELDS.

LONDON, MONDAY, April 26.—The supplies of home-grown Potatoes are on the increase. Since Monday last the imports from abroad have amounted to 300 tons from Antwerp, 210 tons from Rouen, 110 tons from Bruges, 126 tons from Louvain, 335 tons from Dunkirk, 110 tons from Ghent, and 30 tons from Gronengen. The trade generally is heavy, as follows:

York Regents	140s. to 180s.	per ton.
Kent and Essex do.....	80s. to 160s.	"
Scotch	120s. to 160s.	"
Do. Cups	90s. to 100s.	"
Middlings.....	50s. to 90s.	"
Lincolns	120s. to 140s.	"
Foreign	60s. to 100s.	"

COUNTRY POTATO MARKETS.—YORK, April 17.—Potatoes sell at 13d. to 14d. per peck, and 4s. per bushel. LEEDS, April 20.—A fair show of potatoes, which sold readily at 15½d. per 21 lbs. wholesale, and 16½d. retail. MALTON, April 17.—Potatoes, 1s. per peck. RICHMOND, April 17.—Potatoes, 4s. 8d. per bushel. MANCHESTER, April 22.—Potatoes, 13s. to 21s. 6d. per 252 lbs.

PERTH POTATO TRADE.—The potato trade has been dull this week, and prices have a downward tendency except for seed sorts. No dealer is willing to risk a venture in the southern markets at the former rates, owing to the heavy importations from abroad. Retail prices have not experienced any alteration.—*Perth Courier.*

ENGLISH BUTTER MARKET.

LONDON, MONDAY, April 26.—Our market is firm, and quotations for price are about the same.

Dorset, fine	per cwt.	116s. to 118s.
Ditto, middling.....		100s. to 106s.
Fresh.....	per doz. lbs.	10s. to 15s.

CARMARTHEN, (Saturday last.)—A small quantity of new Butter has been brought into this market, the quality far below the standard; but after the fine copious rains which have fallen we shall soon have plenty of grass, and a good supply of first-class butter. Farmers realized this day for new Butter 1s., and for old Butter 10d. to 10½d. per lb. Cheese a dragging trade, from 20s. to 22s. per cwt.

BELFAST, (Thursday last.)—Butter: Shipping price, 100s. to 112s. per cwt.; firkins and crocks, 10d. to 11d. per lb. Bacon, 52s. to 56s.; Hams, prime 70s. to 76s., second quality 60s. to 66s. per cwt. Prime mess Pork, 85s. per brl.; Pork, 43s. to 49s. per 120lbs.; Beef, 120s. to 130s. per tierce; Irish Lard, in bladders, 72s. to 76s.; kegs or firkins, 64s. to 66s. per cwt.

ON THE PRACTICE OF PARING AND BURNING IN DAUPHINE (FRANCE.)

By F. R. de la Trehonnais.

Before I had the pleasure of reading Dr. Voelcker's excellent paper upon the subject of paring and burning, as practised upon the Cotswolds, in Gloucestershire, published in the last number of the Royal Agricultural Society's *Journal*, I had intended to write the following remarks upon the same subject, from notes taken in September last at Grenoble, whither my duties as Vice-president of the Agricultural Section of the Scientific Congress had called me. I am glad other engagements and more pressing occupations have delayed my writing upon this interesting topic, because the perusal of Dr. Voelcker's able paper has enabled me to elucidate several points which I could not satisfactorily explain; and, in reciprocity, I feel certain that the result of experiments and observations made at so great a distance from the Cotswolds, and under such different circumstances, and, moreover, quite independent of his own, will prove interesting to that able Professor, and to those who, like myself, have derived so much pleasure and instruction from his valuable contribution to the Society's *Journal*.

On my way to Grenoble, through the magnificent and fertile plain of Graisivaudan, I had remarked upon many fields a multitude of little mounds, systematically arranged, and undergoing the process of burning; for the careful attention of the men in attendance, in raking fresh soil over those mounds evincing symptoms of entire combustion, at once led me to suppose that a slow charring, rather than incineration, was aimed at. Subsequent inquiries proved that I was right in my conjectures.

Numerous excursions in the neighbourhood, and frequent conversations with the farmers, showed me that this practice of burning was a general system throughout the country, and regarded by all as a most useful operation—equivalent, in fact, to a complete application of manure.

There is nothing for which I entertain so great a respect as those practices based upon the experience of time immemorial, and handed down from generation to generation, to our own time, although perhaps no one was ever concerned in ascertaining the why and wherefore of such practices; the well-established fact of their efficiency, borne out by the evidence of daily experience, being a sufficient ground for their continuance.

This practice was the object of much discussion at the Congress. It was pooh-poohed by several. For myself, I did not view it at first with any high degree of favour, although I was ready to admit that it must be attended with some beneficial results, or else its prevalence would not have become so constant and so general. I resolved, then, to investigate closely the nature of the operation, to ascertain the chemical character of the soil, and to determine as accurately as possible the chemical reaction and other phenomena generated by the process of combustion.

Happily for my inquiries, there were in the Congress several gentlemen residents of the country, who had bestowed upon that subject a great deal of attention; and, with their kind help, by which I was saved a great deal of time and trouble, I have succeeded in satisfactorily explaining the beneficial results of burning, in the peculiarly-constituted soil of the plain of Graisivaudan.

The practice of paring and burning is evidently one of great antiquity. In the "Théâtre d'Agriculture," written more than three hundred years ago by the celebrated Olivier de Serres, we read a very minute description of that operation as practised in his time; and the advantages he enumerates as resulting from this mode of preparing the land, especially for green crops, so fully bears out the conclusions arrived at by Dr. Voelcker and the experience of the farmers in Dauphiné, that I am induced to offer to my reader a condensed translation of Olivier de Serres' description, which no doubt will be new to the public, as the bulky work from which I take it is rather rare, and very little known,

It must be borne in mind that the following passage was written more than three centuries ago; and I wish I could render in adequate modern English the quaint and picturesque old French style of the author:

"Since tilling the land is nothing else but to pulverize and scarify it, to render it capable of receiving, nourishing, and bringing the seeds to maturity, it follows that the operation which effects this result the sooner and the better is the most praiseworthy. It is baking or burning the clod or turf which bears the honour of this husbandry above all other kinds of tillage, by means of which the land is perfectly well prepared; since, being freed from all hardness, roots, and weeds, it is rendered fine, like ashes, and afterwards fruitful in all kinds of crops. The land, being thus renovated, will produce nothing spontaneously (having no seeds left in its bosom), but will gaily grow all that which you will commit to it. Garden-crops, fruit-trees, vineyards, delight in soil thus prepared more than in any other. Meadow-lands are greatly benefited by it, and become richer than anywhere else. In conclusion, this husbandry, by its excellence, may be said to be the quintessence of agriculture, and worthy of admiration; man having found by this artifice the means of accomplishing in ten days that which it takes the sun several years to do, preparing the land in so short a time and so well, and this by fire, that it is rendered subtle and obedient to produce anything. That invention came from the burning of torn-up woods and plantations, from which the people grew abundance of corn. For a long time has this mode of cultivation been resorted to upon cold mountains, which thus derive from fire what they lack from the sun."

Then follows a minute description of the *modus operandi*, which differs very little from that used in Gloucestershire, and still less from what I have observed in the plain of Graisivaudan. Olivier de Serres recommends this operation to be made in May or commencement of June. The turfs should be first dried, then heaped up over a small faggot, the grass side downwards. This heap should be about five feet in diameter at the base, and from four to five feet in height. They should be arranged at regular intervals and in straight lines, for the better distribution of the ashes over the land. The author strongly recommends to avoid a rapid combustion, saying, "Clods and turfs must be constantly heaped up over the mounds from which smoke issues in too great a volume;" and so much importance does he seem to attach to this point, that he says the fires should be

watched night and day. He further remarks that in other countries, where this practice was prevalent, and especially in Piedmont, clods of clay are mixed with the turf. He argues at some length the policy of having one or two large heaps, or else a numerous series of small ones; and although the large heaps offer some advantages, the chief of which is the economy of fuel, he prefers the smaller ones, as being more handy for spreading, and also because a greater area of surface is burnt by the multiplicity of the heaps over the land, and especially, he adds, because the earth is not baked so hard as would be the case with a large heap, where the earth in immediate contact with the fire would be overburnt, and produce no good effect. After considering all these points, the author goes on:

"As soon as the fire is extinguished, the earth will cool of its own accord in a short time, and it will remain in heap until a fall of rain is anticipated, when it should be spread evenly over all the surface, except over the spot where the heaps stood, because there the earth is sufficiently burnt and prepared; this will appear evident from the wheat, in its time, being more luxuriant in those places than elsewhere, as if in those places alone the richest manure had been applied.

"After this, the field should be ploughed, but very lightly, at most three inches deep, in order to mix by little and little the burnt with the raw soil of the bottom. The subsequent ploughings should be deeper; and if the burning has been expedited in June, and good showers have occurred, canaryseed, turnips, &c., either mixed or separate, can be sown; then in the following October rye or wheat can be sown, three or four years in succession."

Further, the author says: "Not only will such earth, burnt and thus prepared, enrich the land, but if carted to other fields, as is done with stable-dung, it will greatly amend them also. All kinds of fruit trees are rejoiced by this earth, if some of it is put around their roots; and it will also be highly beneficial to artichokes, asparagus, and other precious garden plants."

Then meeting the objection of those who think this amendment of the soil is not a lasting one, thinking all the fertilizing elements are destroyed by the action of the fire, he says: "As to the fear of short duration, those alone who have not tried it have this opinion, doubting a thing so well authenticated; for every tillage thus prepared remains strong and vigorous enough to serve as long as can be desired, provided the field be treated as to rotation of crops according to the laws of good husbandry, and not according to the ancient oracle, 'Do not draw all the nutriment from thy field.' All these things weighed and considered, our husbandman shall prefer this mode to any other, if the high price of fuel does not hinder him; and this is the only excuse he can have. And, as a conclusion, he will form his opinion of this practice from the report of those who use it the most, and who say in their *patois*:—

'Those who do not pare and burn,
When others reap, will only glean.'" *

Such were the ideas about paring and burning three hundred years ago, when a time-hallowed experience was the only guide of agriculture. Those who have had the good fortune of reading Dr. Voelcker's able paper upon this subject will not fail to be struck with the great analogy existing between his statements and those of Olivier de Serres; the only difference, a very striking one, showing the immense stride accomplished by science during this long interval, is, that Olivier de Serres gives no other reason for recommending the practice than the experience of ages, corroborated by his own; whilst to this cogent one, Professor Voelcker adds the forcible arguments of scientific analysis and demonstration.

I will now submit to the reader the result of my investigation in Dauphiné, where, as I have stated, the practice of paring and burning exists as a regular and well-established mode of manuring the land at a small cost.

The beautiful plain of Graisivaudan, so well known for its picturesque magnificence and its extraordinary fertility, forms the basin of the river Isère, from the frontiers of Savoie, to the city of Grenoble. Below Grenoble, following the course of the river, it takes the name of Moirans, up to the Rhone, in which the Isère falls. On one side of the valley is the chain of the Alps; on the other, the group of the Chartreuse mountains. Its soil consists of alluvial deposits from the disintegration of the calcareous rocks of the neighbouring mountains brought down by the river Isère, subject to frequent overflowings, and by the torrents from both sides of the mountain boundaries, which from every ravine pour into the valley, along with their turgid waters, streams of calcareous gravel, loosened from the limestone cliffs by the action of the atmosphere, and then borne along by the torrents. Such soil like that described by Dr. Voelcker in the neighbourhood of Cirencester is then eminently calcareous, the proportion of carbonate of lime being generally from 30 to 40 per cent., and sometimes amounts to 50 and 55 per cent. To this is not confined the remarkable analogy existing between these soils, both so greatly benefited by the same operation: the proportion of insoluble silicates is nearly the same in both; and this is an important feature, as I will presently explain.

The mode of paring and burning in the Graisivaudan Valley is identically the same as that described by Olivier de Serres: the turf is pared, dried, and then formed into small heaps over a faggot. The number of these heaps would amount to about 350 per English acre. As it is recommended by Olivier de Serres, the great point of the operation is to produce carbonization, and not incineration, of the superincumbent vegetable and earthy matters. But however carefully the ovens are watched, there is always a certain degree of incineration, in the centre of the heap, of those parts which are in close proximity to the fire: the earthy matter becomes bricky, and of a reddish colour. This, in the experience of the most skilful burners, is to be avoided.

M. Emile Gueymard, a government chief engineer, who has paid great attention to this subject, points also to the overburning of the earthy and vegetable matter as an evil by all means to be avoided. This eminent chemist very truly says that the turf and the clods contain humus, and other matters, which, during the burning process, yield some carbonate of ammonia. It is, then, very evident that, if the temperature be too high, all the humus disappears, and the carbonate of ammonia—a most valuable fertilizing element—is volatized and totally escapes.

Besides the mechanical advantages of paring and burning, which everyone will admit, for strong retentive soils, and those others so ably demonstrated by Dr. Voelcker as resulting from that practice upon the poor clay lands of the Cotswolds, there is another upon which M. Gueymard lays a great stress, that is the transformation of insoluble silicates into gelatinous or soluble silicate immediately available to the plants. The stems of most herbaceous plants contain from 30 to 50 per cent. of silica, giving them that rigidity which enables them to withstan

* Qui non crème, ou non fême,
Quan tous autres moissonnou, il glêne.

the blast of high winds. Silica is very abundant in most soils, since they contain a large proportion of earthy silicates. But silica in such a combination is not soluble, and cannot be assimilated by the plants; for that purpose it must become *gelatinous*. This is effected by the contact with carbonic acid of the air and the humidity of the soil, but by so slow a process, that it often happens the plant cannot find a sufficient quantity for the requirements of its growth.

Earthy silicates, however, when acted upon at a high temperature by alkaline or earthy carbonates, become soluble in acids, and are then available to the plant. Now, all the soils which are found from experience to benefit by paring and burning contain silicates and carbonate of lime; and thus an element of nutrition supplying the plant with what may be compared to the bones of animals, that is, the siliceous coating of their stems and leaves, which enable them to stand erect and rigid, is rendered immediately available. But a certain temperature is necessary to produce gelatinous silica. M. Gueymard says that in all his analyses he found this substance only in the layers of clods and turf which were in immediate contact with the fire, that is, in the very nucleus of the mound; the outward layers, which were only charred, did not contain any. This observation is borne out by the fact, that on the spot where the fire stood the stems of the wheat or hemp plants, which are generally cultivated after burning, are invariably found to be stronger and tougher than anywhere else.

Another chemist, M. Lebreton, goes a step further, and pretends that combustion introduces into the soil a certain quantity of ammoniacal salts, the formation of which cannot be attributed to the remnant of manures and organic matter left in the soil.

I will now examine how the presence of these ammoniacal salts, which I have been able to ascertain do really exist in burnt soil, and in the distilled water with which some of it had been washed, can be chemically accounted for; begging the reader to consider this explanation as a mere surmise, as I am not aware that actual experiments have been made to test its accuracy.

It is well known that some porous substances have the remarkable property of producing the combination of certain bodies by the simple means of the intimate contact produced by the simultaneous passage of these bodies through the pores of that substance. It is thus that alkaline cyanures are now prepared without the help of animal matter, and by *fixing the nitrogen of the air*. The process consists in *passing through a porous substance impregnated with an alkaline solution a mixture of steam, air, and oxide of carbon; this last gas being obtained by the incomplete combustion of charcoal in a furnace suitably heated.*

Now, in the burning of land, the circumstances are precisely the same as in the above process, viz., an incomplete combustion, the gaseous products of which are mixed with air and watery vapour; and the passage of this mixture through a porous mass containing several energetic bases, such as lime, potash, magnesia, and cyanures may then be produced, which, by being subsequently decomposed, must give ammoniacal results.

But this is not all; besides the oxide of carbon, the gaseous mixture contains a great quantity of carbonized hydrogen, since part of the burning process consists in the *distillation of wood*, as well as an incomplete combustion of charcoal. Now, carbonized hydrogen mixed with air, and passing through the porous mass, becomes decomposed; its hydrogen forms ammonia by combining with the nitrogen of the air, and its carbon forms carbonic acid by combining with the oxygen: hence the carbonate of ammonia always found in burnt earth.

With whatever cavils chemists may attack this explanation, it is nevertheless beyond controversy that in the burnt mounds of the fields, in Dauphiné, I have recognized the presence of ammoniacal salts, the existence of which can but in a very small degree be accounted for, from the existence of organic matter in the soil previous to its being burnt: the only source from which it can be produced is undoubtedly the nitrogen of the atmosphere.

Norwood, March 3.

SUPERIOR LINCOLNSHIRE RAMS TO BE FOUND IN LEICESTERSHIRE.

SIR,—For many years the ram breeders in Leicestershire have gone into the county of Lincoln to hire or purchase rams; and at Peterborough fair you may not only find many ram breeders from the county of Leicester, but from many other near and far distant counties, with a view to make a new breed more profitable, by producing more weight of wool and mutton per acre; as actual merit is profit. Men of weak understanding are caught by mania, ornament, and fashion, not considering what an animal makes, so much as what it costs making. It, of course, is bad, to breed animals without profit: an ornamental animal is one thing, and a profitable one is another. We have no business to breed any inferior cattle, sheep, and horses, but the best of its kind, as the best consume no more food than the worst. In trying to breed animals with too great a proportion of fat flesh in proportion to the lean, not only are the stamina and size, but the milk is deteriorated; which caused the once Bakewell *alias* long-horned cattle to degenerate in size, lean flesh, bone, and milk, being now nearly shadows to what they were in Mr. Bakewell's day. Animals may be bred until they nearly lose all their milk, which spoils them for the country dairy-men and the great milk-men in the metropolis; and many of the Bakewell or Leicester sheep have been bred until they have reduced their size, constitution, milk, and lean flesh. Mr. Bryan Ward, at Drayton, on the Welland, Leicestershire, many years back, crossed his pure-bred Leicesters with the best Lincolns he could find, which increased the wool, size, constitution, and lean flesh. Mr. Ward lets yearly upwards of 100 ram sheep, which have improved numerous flocks in many counties. Mr. Sandy, of Holme Pierrepoint, has proved, by the great number of prizes he has taken at the Royal Shows, that he has the best pure-bred Leicesters in the kingdom. SAML. ARNSBY.

Mill Field, Peterborough, April 10, 1858.

MY WINTER GARDEN.—The March breeze is chilly, but I can be always warm if I like, in my winter garden. I turn my horse's head to the red wall of fir stems, and leap over the furze-grown bank into my cathedral, wherein, if there be no saints, there are likewise no priestcraft and no idols; but endless vistas of smooth, red, green-veined shafts holding up the warm, dark roof, lessening away into endless gloom, paved with rich brown fir-needle—a carpet at which nature has been at work for forty years. Red shafts, green roof, and here and there a pane of blue sky—neither Owen Jones nor Willement can improve upon that ecclesiastical ornamentation; while for incense I have the fresh healthy turpentine fragrance, far sweeter to my nostrils than the stifling narcotic odour which fills a Roman-catholic-cathedral. There is not a breath of air within, but the breeze sighs over the roof above in a soft whisper. I shut my eyes, and listen. Surely that is the murmur of the summer sea upon the summer sands in Devon, far away. I hear the innumerable wavelets spend themselves gently upon the shore, and die away to rise again. And with the innumerable wave-sighs come innumerable memories, and faces which I shall never see again upon this earth. I will not tell even you of that, old friend. It has two notes, two keys rather, that Æolian harp of fir-needles above my head; according as the wind is, east or west, the needles dry or wet. This easterly key of to-day is shriller, more cheerful, warmer in sound, though the day itself be colder; but grander still, as well as softer, is the grand soughing key in which the south-west wind roars on, rain-laden, over the forest, and calls me forth—being a minute philosopher—to catch trout in the nearest chalk-stream.—*Charles Kingsley in Frazer's Mag.*

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR APRIL.

Although the weather has been somewhat favourable for the time of year, the frequent changes in it have had the effect of checking the progress of vegetation; nevertheless, our accounts from most of the leading agricultural districts, in reference to the general appearence of the young wheats, are very favourable. Everywhere they are looking strong and healthy, and promise a good return to the farmer. The sowing of Lent corn was concluded about the usual period, and as respects the plants no reasonable complaints can be made.

The all-engrossing topic of discussion in agricultural circles has naturally been the almost continuous decline in the value of wheat. Some persons contend that that produce has run down to a point at which speculation is sure to commence, whilst others are of opinion that prices have not seen their lowest range. The position of the trade, we may remark, is very different from what it was at this time last year. Then, the French ports were closed against exports, and our millers were not subject to direct competition in an article fully equal in quality to their own. This competition has induced great caution in buying wheat where otherwise it would not have existed; not that our importations have been large, but the almost entire absence of orders from this country has compelled the French millers and the usual shipping houses to forward to agents in this country, and the orders have for the most part been to sell immediately on arrival. So long as this system continues—and it is not confined to flour only, as similar advices have been received with most of the wheat imported from Germany and the Lower Baltic ports—so long shall we have to report dull and, perhaps, drooping markets, even though the stocks of foreign produce in warehouse have become much reduced. We must bear in mind that very large quantities of wheat remain in the hands of the farmers both in England and throughout the continent, as well as in the United States. An extensive speculation, and a determination to warehouse rather than sell at present prices, might improve the trade to some extent; yet, on the other hand, we are fully aware that any upward movement in value in this country would be followed by a large outflow from America, where the shipping season is just commencing. As yet, very little of last year's wheat has been exported, and the shipments of flour have been only moderate—those of other articles having fallen off considerably, as will be seen by the annexed official return made up to the 13th of April, current year:—

EXPORTS OF BREADSTUFFS FROM THE UNITED STATES TO GREAT BRITAIN AND IRELAND SINCE SEPT. 1, 1857.

	Flour. brls.	Meal. brls.	Wheat. bush.	Corn. bush.
1857-58	744,339	123	3,415,596	2,351,437
1856-57	775,183	186	7,011,580	4,102,980
1855-56	735,988	5,719	3,755,317	4,337,877
1854-55	130,704	5,235	206,545	4,649,478

TO THE CONTINENT.

	Flour. brls.	Wheat. bush.	Corn. bush.	Rye. bush.
1857-58	182,143	209,751	14,901	—
1856-57	379,388	2,716,791	496,913	216,162
1855-56	619,964	2,156,734	214,287	1,426,210
1854-55	7,646	—	295,645	35,541

From the above figures it must be obvious that a large quantity of produce is still in stock in the United States, unless, indeed, the extent of last year's crop has been greatly over-estimated. Apparently, therefore, there is no prospect of any important movement in the value of wheat for some time.

As regards spring corn we may write differently. Our own crops are wholly inadequate to meet the demand; consequently, we shall no doubt use up every quarter of barley, oats, beans, and peas imported during the season, without producing any important change in the quotations. Compared with wheat, spring corn is commanding good prices. Many of our large growers, rather than sell at present quotations, have determined to hold over their wheats till next year. Possibly this is sound policy, as we can scarcely anticipate two consecutive years of such enormous *general* abundance as last season produced, and we do not see any reason to look forward to other than a steady increase in the consumption of the better kinds of food, as the trade and commerce of the country are unquestionably steadily recovering from the effects of the late severe panic.

We have continued to import very large quantities of potatoes from the continent. In some measure, they have made good the deficiency in our own crop and rendered the trade somewhat heavy; nevertheless, good and fine samples have sold at from 160s. to 180s. per ton. The quantity of sound potatoes now on hand in this country is reduced to a narrow compass; but on the continent, especially in France and Belgium, the supply is large for the time of year.

Throughout the month the wool trade has been in a most depressed state, and prices of all kinds of wool have given way nearly, or quite, 1d. per lb. The public sales are likely to go off heavily at further depressed rates, since nearly or quite 60,000 bales will be offered during their progress.

Store stock, arising from the heaviness in the demand for fat beasts and sheep, has ruled heavy and drooping. The business done has been very trifling.

Throughout Ireland and Scotland there has been no important movement in the corn trade. Wheat has continued dull and flour has ruled lower, but other articles have mostly supported former terms. From Scotland steady shipments of produce have been made to the south, but the exports from Ireland have shown a great deficiency when compared with many former corresponding seasons.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that the trade of the country is recovering from the effects of the late panic, that consumption is rather on the increase, and that the importations from the continent still continue limited—compared with many previous corresponding periods of the year—the cattle trade has been in a very unsatisfactory state during the whole of the month, and a severe fall has taken place in the quotations. Whatever may have been urged to the contrary in some quarters, it is now clearly apparent that production has over taken consumption. And who, we may ask, can feel surprised at this result, which reflects the highest credit upon our breeders and feeders? and, further, may we not

rest satisfied that even low prices will not have the effect of lessening the producing powers of the United Kingdom? The present value of beasts in our markets—the general top quotation being only 4s. per 8lbs.—may induce greater moderation on the part of the breeders as to price; certainly, the graziers have lost very large sums of money on nearly every head of stock sold during the last three or four weeks. At one period, store animals were selling considerably above their value; but the prosperous state of commerce, and the enormous consumption, induced graziers to add largely to their supplies, and the consequence is that a serious loss has been sustained. In all dealings, it should be borne in mind that there is a limit to consumption, consequently to price—the latter, of course, being regulated by the former; hence, to speculate in stock beyond what may be considered a fair sum—we here refer to the usual transactions only—is a matter which frequently leads to disappointment and loss. Had it not been that France has imported largely for some considerable time—indeed, even now, both beasts and sheep are drawn from Spain and Holland for immediate consumption—we should have had a much larger influx of stock from the continent, and, perhaps, even a greater fall in the quotations. As it is, however, the importations have been reduced to almost a nominal amount. But when we consider that the production of live stock in France is increasing under what may be termed good auspices, and that great exertions are being made to improve the weight and quality of the various breeds, by means of importations from this country, it is by no means improbable but that, in the course of a very few years, France will be wholly independent of any other country for the supply of food: hence, the surplus produce of Holland will again flow in upon us, and prices may suffer in the general run of years. We must not affect to despise the production of live stock in Holland, because in that country a marked change has taken place in the production, especially of sheep. On the passing of the tariff, the arrivals of sheep from that country were, with the exception of their carrying a full average quantity of internal fat, of an inferior class, and only suited for consumption in very poor localities. Now, however, the case is different. The legs of the animals have been shortened by extensive crossings with English breeds, the tails have been well cropped, and not a few of them have sold as high as 65s. each. Thus, whenever France produces an adequate amount of meat for home consumption—we will not say that eventually she will be able to export much, though exportations may be looked for,—our breeders and feeders must be prepared for additional weight in every head of stock imported from the continent, and which, as a matter of course, must have considerable influence upon value. For some years we imported enormous *numbers* of both beasts and sheep; but they failed, owing to their light weighing qualities, to have any depressing influence in our markets: still, it is an open question, and one of no ordinary importance, whether we shall have a return to what may be termed high periods for either beasts or sheep.

We have already remarked that live stock has considerably declined in value, and the fall will be better understood, when we state that the best Scots have scarcely produced more than 4s. 2d., against 5s. in the corresponding month in 1857, and that the difference in the price of the best Downs in the wool has been nearly 1s. 4d. per 8 lbs. Lambs, calves, and pigs have fallen to nearly the same extent, and the increase in the supplies of the latter in nearly every county in England, including Ireland, is very remarkable. It will, however, be recollected that in April, last year, there was considerable excitement in the trade, arising from the publication of an order in council, prohibiting the importation of stock from some parts of Germany, owing to the discovery of an extensive murrain, which happily did not extend itself; nevertheless, other months might be selected to prove that production has increased, and the mania for buying at almost any price has subsided into what may be termed a more reasonable state of things.

Very few complaints have reached us from any quarter in reference to the health of the stock. Everywhere, about an average supply of food is on hand; but the graziers complain of the shortness of grass in the pastures, and of the continuous changes in the atmosphere having had the effect of retarding the progress of the grass-crop. The lambing season has progressed remarkably well. There has been a strong and healthy fall, and the number of twins is generally remarked upon by our correspondents.

The following return shows the imports of foreign stock into London during the month:—

Beasts	1,063	head.
Sheep	4,082	,,
Calves	830	,,
Pigs	23	,,
Total	5,998	,,
Same time in 1857	4,814	,,
,, 1856	1,924	,,
,, 1855	4,253	,,
,, 1854	4,760	,,
,, 1853	14,787	,,
,, 1852	5,444	,,

The total supplies shown in the Great Metropolitan Market have been as under:—

Beasts	17,950	head.
Cows	400	,,
Sheep and lambs	104,380	,,
Calves	1,332	,,
Pigs	2,097	,,

In April, 1857, there were exhibited 18,601 beasts, 460 cows, 92,810 sheep and lambs, 1,240 calves, and 2,025 pigs; hence, the principal difference in the supplies during the past month is an increase of about 12,000 head of sheep.

From Norfolk, Suffolk, Essex, and Cambridgeshire 11,700 Scots and shorthorns have come to hand. The receipts from other parts of England have amounted to 2,260 of various breeds; from Scotland, 920 Scots; and from Ireland, 910 oxen, &c. This is a large number to be drawn from Ireland in one month; but, no doubt, had the manufacturing districts been more active, a portion of the supply would have been sent to Manchester.

Beef has sold at from 2s. 10d. to 4s. 2d.; mutton, 3s. to 5s.; lamb, 6s. to 7s.; veal, 4s. to 5s. 4d.; and pork, 3s. to 4s. 4d. per 8 lbs. to sink the offal.

COMPARISON OF PRICES.

	April, 1855.		April, 1856.		April, 1857.	
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
Beef, from	3 2 to 5	0 .. 3	2 to 4	10 .. 3	4 to 5	0
Mutton ..	3 2 — 5	0 .. 3	6 — 5	8 .. 4	6 — 6	2

Pork	3 4 — 4	4 .. 3	6 — 4	8 .. 3	8 — 5	0

For the time of year, Newgate and Leadenhall have been very extensively supplied with both town and country-killed meat. The general demand has ruled heavy at drooping prices. Beef, from 2s. 8d. to 3s. 8d.; mutton, 3s. to 4s. 2d.; lamb, 5s. to 6s. 4d.; veal, 4s. to 5s.; pork, 2s. 10d. to 4s. 2d. per 8lbs., by the carcase.

EAST SUFFOLK.

The months of January and February were not so winterly as former years, yet attended with light frosts, and scarcely any downfall, which brought the land into beautiful tillage, and some quantity of spring corn was sown. March set in with piercing north-east winds, severe frost, and heavy fall of drifting snow, which stayed the progress of sowing; this continued till the middle of the month, from which time, although the weather has been variable, it has been highly beneficial to spring sowing, and we can scarcely record when the seed has been put in more advantageously for a crop. Three weeks since, wheat, from the weather in March, was looking rusty, and on some light lands, where the snow was drifted off, the blade was hardly visible, and fears arose as to its recovery; the late, and present fine weather has quite established it in colour, and indicates up to this time the appearance of an abundant crop, and we consider it as forward as on average seasons. The prices of barley, beans, and peas have been on a par with wheat. There is a great portion of last year's large crop in the growers' hands, many of whom have concluded, rather than sell 63lbs. per bush. reds at 42s. per qr., to hold over on rick. Barley is quite out, and maltsters leaving off steeping. Beans and peas—a rarity to see a sample with us. Grazing has been very unprofitable this season, and we know of fat bullocks having been selling at lean prices. —April 22.

SOMERSETSHIRE.

We are now favoured with as fine clear sky as is ever witnessed in this month, which has told accordingly upon the growing crops of wheat, the forwardness and luxuriant appearance of which have not been exceeded for several years. It is generally acknowledged that our prospects depend on a continuance of dry weather, and no heavy rains for an extra fine crop, but that even the usual fall of rain will have a contrary effect, more especially as regards the quality. Should the forcing heat of the present month be followed by anything like it in the next, we shall have an early kerning. The land is certainly better prepared for dry forcing heat than for many preceding years; yet if it continue, it will tell on the late-sown crops, barley and beans especially. Winter beans are just coming into bloom, and are very promising. The early-sown spring beans are nicely up: on shallow soils a dry month will try them greatly, and must lessen their produce. The early-sown barley and oats are very forward. Vetches and the artificial green crops have grown very fast since the rain, and we have more water in our brooks and pools than at any time during the winter, which will prove of great service. Our meadows are just ready for turning out, and their favourable appearance has tempted buyers to give much higher prices than last year, for poor sheep one-year-off. Devons have fetched as high as 52s. to 54s., couples 50s. to 60s.—prices by no means justified by the probable value of mutton or wool. Poor stock has come down, but not by any means in proportion to fat stock, which are a complete drug, and must entail loss upon the dealers. We have promise of fair blossom on the fruit-trees; the apple-trees being expected to display their floral adornments within a fortnight. Potatoes, which had been cut down by early frosts, have, within the last few days, again sprung up above ground, and, if there be no more frost, will go on rapidly. Some little business was done last week in wheat at the advance, which has since been more than lost. Most of the wheat in the farmers' hands can be kept back; and where it is held in large quantities this will be accomplished with but slight risk at present unusually low prices; so that it is probable we shall have short supplies before next harvest: and if foreign supplies also fall off, there is every probability of wheat being able to more than maintain its present value. The late fall in Mark Lane has been more firmly withstood in our market than any previous depreciation. White wheat, weighing 64lbs. per bushel, is quoted at 5s. 9d., 62lbs. at 5s. 6d.; red, 60 to 61lbs. 5s., 62lbs. 5s. 3d., 64lbs. 5s. 4½d. to 5s. 6d. Beans are in demand, at 4s. 9d. to 5s. 3d Oats are scarce, and sell readily at 2s. 9d. to 3s. 3d. Barley does not lie on hand, and realizes improved prices. Flour fetches 31s. to 32s. per 280lbs. Mutton in the wool is sold for 6½d. to 7d. per lb.; beef 9s. 6d. to 10s. 6d. per score, but very little this week worth the latter price. Green bacon 6d. to 6½d. per lb.; pigs 9s. per 20lbs. Little doing now in cheese, the prices lately having been more stationary, the best worth 60s. per cwt. upwards. No quotable price for wool, transactions being unreported.—4th Month 23.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

Like the previous months of this extraordinary year, April has been without the usual characteristics (shower and sunshine), dry weather having far preponderated, with, however, a good deal of cold in the early part of the month, so that the progress of vegetation, on the whole, has not been rapid. This, however, is more in favour of a crop of wheat, as the blooming time is more likely to be out of the reach of rough weather. The young plants continue to look well and promising, and the seed-time for Lent corn has been most favourable; but more rain would be serviceable, especially to the grass, which is backward and short.

The wheat crop in Europe is generally well reported, especially in the South of France, Spain, and Italy; but on the coast of Africa and in the French colonies drought is doing harm to spring corn, and there were some fears for wheat. The anticipations that other Italian States would follow the example of Rome, in a permission to export, have been only partly realized. Naples, at last, has come out with an act of grace in favour of growers there; the export of wheat being permitted on payment of one silver ducat per cantar, equal to about 8s. 6d. per qr., and only reaching to the 15th June, which is nearly tantamount to a prohibition, though a few choice parcels for a limited use may come on to France and Britain. We now, therefore, pretty well know the worst of it; and this news coming with fine weather, has not prevented a rise in the market here of 1s. per qr., which is about the balance of the month's gain, after several fluctuations.

The idea of last year's fine crop has been bandied about as though it could be grown and shipped for nothing, and the contents of every foreign stackyard was on board ship, and the labouring fleets all bound for Britain. But if England has lost heart, and her imperial ally has caught the infection, it is not so with Germany, the United States, or Russia. They, at least, think they ought to be paid for their work and produce, and very good pay may be yet in store, should any accident occur between now and harvest, which is yet fully four months distant; and the short stocks in London, after this year of plenty and continued imports, show a consumption going on unprecedented.

Dating the new era for farmers from the last Bill, it appears the last average price is 12s. 8d. below the average of the eleven years preceding; and as there is no inducement to increase the rate of shipments in the present state of prices here, it seems fair to look forward to receiving only about 1,200,000 qrs. more foreign wheat as the total arrivals before the maturity of our own crop, which is below one month's consumption; and should we advance, our friends abroad, with telegraphic means of information, instead of forcing off their stocks, will be more likely to hold for better prices. As it is, the surplus at disposal is only out of last year's produce, as the stock of old on hand everywhere was much below an average amount. The falling off in the weekly deliveries indicates a general resistance of any further depreciation; and, if still more straitened, they would soon settle the question, for the abundance of money waiting for speculative opportunities would be then partly directed to the corn trade.

In the Baltic less than an average quantity of wheat is likely to be shipped. At Danzig, the top quotation was about 45s.; at Stettin, 41s. 6d.; Hambro' quotations for red 62lbs. Holstein were 44s. 6d., 61lbs. white 45s., extra red Marks and Saale 45s. 6d. In Rotterdam, white Zealand was worth 45s.; the best heavy red Rhine bringing 46s. to 47s. per qr. Antwerp advices note 43s. as the value of Louvain red. Paris quotes about 39s. as the highest price. Nantes, 40s. for red, and 43s. the best white; first quality flour being held at 31s. 6d. (only worth 34s., duty and expenses paid, in London). Madrid quotes 53s. to 60s., and Alicante 52s. 6d. for Taganrog. The rates at Odessa were 38s. to 44s.; at Taganrog and Berdianski, 37s. to 41s. Prices at Galatz, freight included, were 38s. per qr. New York was high, the best southern red being about 42s., and best white 50s. Some reports made the stocks in the several Lake Ports reach to 700,000 qrs.; but this seems an exaggeration, and there were few symptoms of giving way.

The first Monday commenced on moderate supplies, both English and foreign, with a very slender contribution from Kent and Essex, as the morning's addition; this being in fine condition, millers took it off slowly at 1s. per qr. advance, and their attention was also more turned to fine foreign at full prices. The country markets mostly exceeded this improvement—Manchester, Leeds, Birmingham, and Bristol agreed with it; Hull, Newark, Boston, and most of the Saturday's reports made

the rise 1s. to 2s.; Woodbridge and Leicester holding for 3s. more. The rise at Liverpool, on Tuesday, was 1d. to 2d. per 70lbs., and Irish customers, on Friday, produced another rise of 1d. per 70lbs., and London closed with a better appearance.

The second Monday was altogether less plentifully supplied, excepting the morning's supplies from Kent and Essex, and another 1s. was then gained, though paid grudgingly, foreign participating in the improvement. Hull, Leeds, Boston, Spalding, and Portsmouth exactly tallied with the London report; Wolverhampton, Manchester, Newark, and Gloucester made no change; Birmingham was in favour of buyers. Newcastle, Leeds, and Bristol, influenced by a favourable change of weather, were 1s. per qr. lower; and though Liverpool was 2d. per 70lbs. higher on Tuesday, this advance was barely maintained at the final market, a sudden summer-like temperature having subdued the upward tone in London.

The third Monday had less foreign wheat than the two former, with only a moderate quantity of home-growth, and few samples during the morning from Kent and Essex. With the forcing weather came a general change of feeling, which being indicated by the state of the last country markets, a reduction of fully 2s. per qr. was necessary to clear off the small show, which was not effected till about the close of the market, some accepting even still lower terms. Very few country markets fully responded to this feeling, but among them were Sheffield and Spalding. Birmingham found a ready sale at only 1s. per qr. less money. Manchester, Leeds, and Bristol were nearly as much lower as London, but at the week's end advices were less desponding, and the final reports were little altered from the previous week. London, too, on Friday, had a firmer tone. Liverpool was lower at both markets, 2d. per 70lbs. reduction being noted on Tuesday, with 1d. to 2d. per 70lbs. further on the last report.

The fourth Monday was better supplied, with the weather fine; but as the arrivals from Kent and Essex were small, there was some reaction, and fully 1s. per qr. recovered of the previous decline.

The general averages being fully a fortnight behind the business done, do not immediately show the progress of markets; but it is remarkable that the lowest average, of the 19th of April (43s. 1d.), had the sales reported as only 72,171 qrs., and the last (43s. 2d.) was only 76,791 qrs., making the fortnight's deliveries 29,572 qrs. less than during the same period last year, and this reduction in the deliveries has immediately been followed by a better tone.

The month's supplies into the port of London have been 17,414 qrs. English, and 23,834 qrs. foreign; making the weekly average 10,312 qrs., against 15,259 qrs. weekly in April, 1857. The total imports in March into the United Kingdom were 201,622 qrs. wheat, and 529,590 cwts. flour.

The flour trade, after undergoing some fluctuations, is left little altered. Town qualities have kept to the price at which they commenced, viz., 40s. per sack; Norfolks, beginning at 29s. and reaching 31s., fell back again to 29s. to 30s.; American and French remaining unaltered. The latter, though there has been a steady moderate influx, has lost money; the four marks being only worth 34s. per sack here, on 29s. the value at Paris, is fully 1s. per sack against imports; and at Nantes, the rates being 31s. 6d., leaves only 3s. 6d. per sack for duty, shipment, land-carriage, and commission. The imports into London during the four weeks were 65,080 sacks country flour, 7,269 sacks foreign (mostly French), and only 504 brls. from the United States; leaving the weekly supply about 2,400 sks. 5,200 brls. below March, but about equal to April last year.

The barley trade has scarcely varied throughout the month, excepting small occasional purchases, the malting trade being over, and therefore the best parcels have become neglected, and in future must be used for distillation. Large arrivals have during the last three weeks come from the Mediterranean, but the low rates making these sorts much cheaper than oats, they go off for mixing, and the better sorts for grinding, while but small quantities fit for the distiller come to market, the purchases being made direct. Stocks now seem working close every where, both in foreign ports, London, and the country, and, as we have before hinted, all that can come will be wanted, and a purchase of 5,000 qrs. at Odessa for June delivery at 21s. cost and freight confirms the opinion. The deficiency of fine sorts in our own crop has lately led to the use of the best French both for seed and malting, and though thin it has vegetated kindly and answered well, at Nantes the price for such is 26s. per qr. free on board. The imports for four weeks have been only 7,681 qrs. English into London, but of foreign 56,085 qrs., giving a weekly average of 15,941 qrs., which is below April 1857 by 11,824 qrs., though 6,710 over last March. The malt trade has been steady throughout the month, with little or no alteration in the value of first qualities.

The great deficiency in the supply of oats has raised their value during the month fully 1s. 6d. per qr., and the probability is that until the Russian arrivals begin to appear, the market will be tight. As Ireland is known to have grown less than last year, and our own crop was below an average,

foreign ports have all been stirred up by an inquiry which has reached to New York. At Hambro' they are quoted 25s. to 27s. per qr., with offers of 40½lbs. Swedish at the outports at 23s. 6d. At Rotterdam Zealand feed are quoted 25s ; at Nantes 26s. 6d. as well as at Bordeaux. The rise referred to took place on the first two Mondays, say about 9d. on each day ; this was checked on the third Monday by better supplies, though not above an average, and more confirmed on the last week, when they again fell off. The imports into London during the four weeks were 2,050 qrs. English; 4,447 qrs. Scotch ; 8,499 qrs. Irish ; and 44,082 qrs. foreign : making the weekly average 14,769, which is more than 5,000 qrs. below the weekly consumption ; so that if it had not been for granary stores, rates must have greatly increased, but these are fast consuming. In April, 1857, the average supplies were 39,121.

Beans and peas throughout the month have rather improved in value. The first Monday brought a rise of 1s. on the former, which has been supported. Boiling peas, after much neglect by a great deficiency as respects supplies, have sold, though slowly, at fully as much money ; and those for hog feed, notwithstanding their high price, being very scarce, have continued to be placed in retail, notwithstanding the general use of cheaper substitutes. The consumption of beans will lessen with the advance of the season ; but as Egyptian shipments are less free than expected, there does not seem much probability of lower rates. The imports of beans during the four weeks into London were in English qualities 3,158 qrs., in foreign 8,012 qrs., making an average weekly supply of 2,792 qrs., which is nearly 1,000 over February and March, and is more than double the supply in April, 1857. Of peas there have been in the same time only 553 qrs. English, and 374 qrs. foreign, the month's supply not equalling a week of former times ; but boilers have been little used, and substitutes have been found for pig food in abundance, wheat itself being cheaper than duns and maples.

The supplies of linseed running short in London, and exports being fair, prices have improved fully 1s. in the course of the month, notwithstanding the heaviness of stock. In foreign ports, too, the prices remain dear, Odessa quoting up to 55s. So that till a new and good crop is gathered the range of prices seems likely to be high. The more liberal use of cake has greatly contributed to this, its nutritive properties to the animals fed, as well as the quality of the manure they yield, making a larger demand.

The consumption of the potato crop, notwithstanding the free imports, and the high rates of the small remainder fit for use, have stimulated the enquiry for maize for Ireland, where it has been rising, and become quite a necessary, and it is probable that its comparative dearness may take off the lower qualities of wheat, which are relatively cheaper.

The seed trade has been very disappointing to importers and the trade generally, prices having given way from their height 20 to 25 per cwt., and much foreign as well as English remaining on hand, the rates paid have become irregular, some few parcels still going off for seed this season ; but the reduction in value has brought speculation into the trade, and those determined to get out at any cost may now find buyers, both of red seed and trefoil, at low rates, say 40s. to 42s. per cwt., for fair foreign red Seed. Canary has unexpectedly remained dear, 96s. being quoted even at Rotterdam, whence it was thought much would come. Mustardseed, too, after long neglect, has got up in white qualities, but brown remain out of favour. Hempseed has kept its value ; and the reports of the failure of the crop of tares in the Baltic have turned out true, and the few parcels appearing have obtained extravagant prices. Rapeseed was reported a partial failure and therefore rising, but later accounts are not so unfavourable ; and in France it looks well. Carraway and Coriander have found a retail sale at former prices.

COVENT GARDEN MARKET.

LONDON, Saturday, April 24.—Trade is brisker than it was last week. Strawberries are making their appearance in larger quantities. Of Pears, Easter Beurré, and Ne Plus Meuris may still be obtained. Oranges of all kinds are good and abundant. Among Vegetables are Asparagus, Rhubarb, and Scakale. Winter Greens are plentiful. French salading is excellent; it still consists of Cabbage Lettuce, Barbe de Capucin, Batavian Endive, and Turnip Radishes. Cornish Broccoli realizes from 1d. to 2d. a head. French Beans are very plentiful. New Potatoes are making their appearance. They fetch from 2s 6d. to 3s. per lb.; Peas, from 3s. to 4s. per punnet; and green Artichokes, 6s. to 8s. per dozen. Cucumbers plentiful. Best samples of old Potatoes have advanced in price. Cut flowers chiefly consist of Orchids, Gardenias, Heliotropes, Poinsettia pulcherrima, Geraniums, Violets, Mignonette, Heaths, Primulas, Camellias, Cyclamens, Tulips, Hyacinths, and Roses.

SPIRITS.

LONDON, Saturday, April 24.—There is a slow inquiry for Rum, the stock of which is seasonably good, at our quotations. Brandy continues a dull inquiry, but we have no change to notice in its value. Grain spirit sells slowly, on former terms.

WOOL MARKETS.

ENGLISH WOOL MARKET.

LONDON, Monday, April 26.—Owing, in some measure, to the approaching sales of colonial wool, at which nearly 60,000 bales will be brought forward, our market is in a very depressed state, and it is difficult to sell any kind of home-grown wool except on lower terms.

Per pack of 240lbs.

BRADFORD WOOL MARKET.—The transactions during the week and to-day are trivial. The supply of bright-haired wool is exceedingly limited: nor are staplers disposed to increase their stocks until the pending sales by auction are past. In prices there is but little alteration; but the tendency is downward. Noils and short wool are dull of sale, notwithstanding the very small quantity now producing. YARNS: There are more inquiries by the export houses, but not more sales making. Leipzic Easter fair is now on, where large quantities of worsted goods are usually sold by the German manufacturers, who draw their supplies of yarn from this market. A week or two hence, more business may be looked for from that quarter. The consumption by the home manufacturers is steady, but limited. Prices are ruinously low, and spinners strictly adhere to short time working, besides having much machinery unemployed. PIECES: The attendance of merchants is more numerous to-day. There is a fair amount of business doing in fancy goods suited to the approaching season, but there is no improvement in Coburgs or Orleans cloths. In coatings there is more doing.—*Second Edition of the Bradford Observer of Thursday last.*

LEEDS WOOL MARKET (ENGLISH AND FOREIGN) April 23.—Stocks of English wool are very light, as is generally the case at this season of the year, but they are amply sufficient for the demand. Many buyers are looking forward with interest to the approaching public sales at Halifax and Bradford. The prevailing opinion seems to be that the prices obtained at the last sales will not be again secured. The demand for yarns and pieces during the interval would seem to furnish ground for this opinion. Buyers of foreign wool are also looking forward to the next sales of colonial, and are not disposed to buy freely till prices are established. The opinion is that they will be lower, but some persons expect they will be about the same as last sales.

LIVERPOOL WOOL MARKET, APRIL 24.

SCOTCH.—There is more general inquiry for Laid Wool, at our quotations. White Highland is also more in demand. The late public sales of Cheviot, to close some old accounts, has rather depressed the market for the moment, and we have had little doing by private sale.

	s.	d.	s.	d.
Laid Highland Wool, per 24lbs.	11	6 to	12	0
White Highland do	14	6	16	0
Laid Crossed do..unwashed	13	0	14	0

Do. do..washed.....	17	0	20	0
White Cheviot do..washed.....	28	0	30	0

FOREIGN.—Notwithstanding the prices were low at the public sales just closed, and the quantities sold were considerable, still the demand since for deep-grown Wools has been good, and fully late rates obtained. On the whole the market looks healthy.

A TREATISE ON ROAD LEGISLATION AND MANAGEMENT. By Richard Bayldon, Methley, near Wakefield.

OPINIONS OF THE PRESS.

"Mr. Bayldon is a road surveyor of whom we have before spoken, and what he has to say on such subjects deserve consideration."—*Builder.*

"A very able treatise by a gentleman of great acuteness and experience, on a subject of general interest, which we beg, specially, to recommend to trustees and mortgagees of turnpike roads, as well as to carriers, mine owners, and others."—*Staffordshire Sentinel.*

"Mr. Bayldon deals sensibly and suggestively with a very difficult question. The author deprecates the system of confiscating, even partially, the turnpike debts, and concludes by some useful and thoroughly practical remarks on the management of tolls, and repairing turnpike roads and highways."—*Law Times.*

"The treatise is, although condensed, yet comprehensive and practical, embracing both highways and turnpike roads, and it is difficult to single out any point connected with the subject that its intelligent author has not clearly set forth and explained."—*Barnsley Times.*

"To commissioners and officers of turnpike roads, and to all road surveyors, this little work must be of the greatest value. At the same time, there is matter in it that will be of interest to our legislature and the general public. Under the head of repudiating turnpike trust debts, Mr. Bayldon offers some very sensible remarks."—*Leeds Mercury.*

"The author of this very excellent work has proved himself to be a practical road surveyor, with a much greater extent of knowledge than is usually evinced by men of his class. There is no doubt such a treatise was wanted, and Mr. Bayldon's extensive knowledge and experience as surveyor of the Leeds and Wakefield and other trusts qualifies him for the task."—*Doncaster Gazette.*

"This is a useful practical treatise on an important subject, by a man fully competent to discuss it. Mr. Bayldon's object is to point out how the debts of turnpike trusts may be liquidated, and by what simple measures public roads may be kept in much better repair, and at less expense, than at present. We cordially recommend it to the perusal of all concerned in the management of highways, and to all who are unfortunate enough to be owners or trustees of turnpike roads."—*Economist.*

"This is a concise and practical treatise. Mr. Bayldon points out clearly the injustice of the course which has been adopted by our legislature in repudiating the debts of turnpike trusts. He also deals ably with the much vexed question, as to the removal of toll bars out of the streets of the Metropolis, and other large towns and populous districts. The book contains a considerable amount of information concisely stated and well arranged as to the practical management of roads; and we recommend it to the notice of commissioners and officers of turnpike roads, surveyors of highways, overseers of the poor, and all others interested in the matters to which it relates."—*Knight's Official Advertiser.*

"This little work of 100 pages, which is just out, we most cordially recommend to the commissioners and officers of all turnpike roads, as well as to solicitors and surveyors of highways; and if our legislators in both Houses of Parliament would give a few hours' attention to the reading of it, we feel confident they would find their labours well repaid. The suggestions for the payment of turnpike trust debts, the reasons for removing toll bars from populous localities, and the proposed regulations for encouraging and enforcing the use of flat broad wheels for heavy carriages, are all thoroughly practical and grounded on long experience His concluding remarks on the management of tolls and the repairs of public roads are excellent; and we are assured by men of practical experience that if Mr. Bayldon's system was fully carried out, the mortgage debts could be honestly paid off, and the condition of all our roads greatly improved, whilst the expense of repairing them would be reduced at

free. It is a well-known fact that these checks, together with the other branches of your management, has kept this important line of road in far better order than any other similar length of road in the neighbourhood; the public at the same time enjoying such a freedom of tolls as belongs not to any other of the twenty different turnpike-trusts around the Borough of Leeds. Thus proving the wisdom of your system when properly carried out.

Your tolls, as regards weights on different shaped wheels, from being so much different from the scales adopted on any of the other lines round Leeds, must have been well considered by you before it was adopted, inasmuch as it has proved, after 15 years' experience, quite satisfactory to all reasonable persons that we have conversed with on this important subject. Indeed, the charges are so just and equitable on different kinds of wheels, (and on destructively-shaped wheels no more than necessary,) that they must tend to preserve the roads, and act beneficially on the funds of your trust, as well as to all others, whether turnpikes or highways, on which your improved-shaped wheels pass over.

4.—Your suggestions for repairing roads, both turnpike and highway, are excellent, because so practical; being in fact the plans which we have carefully observed have been carried out on the different roads round Leeds placed under your care for nearly the last 20 years. But we cannot but express our regret that you should have found it necessary to go into such minute details for the use of surveyors of roads, more particularly round Leeds, as your system of management has been so fully exposed to the public for so long a period on the Leeds and Wakefield road. You describe nothing in your work but what we have observed you have adopted for a long time, and therefore there is no theory about it—it is all actual practice. How it is that all other surveyors in our neighbourhood have not yet followed out your method to the full extent we cannot tell. They must have *seen* the operation, and the *result* of your system as regards perfect road-making, and your treatise tells us how it has abolished road debts; but the French have a proverb, which says, that "It takes a great deal to *observe* what may be *seen* every day;" and therefore your system, although *seen*, it is quite clear has not been sufficiently *observed*, or else other surveyors around Leeds would have adopted your plans, and thus given us the benefit of good roads at a reduced expenditure of repairs.

We have further to remark, that as we have had almost daily, for a number of years past, several horses drawing our carts and waggons on that part of the Leeds and Wakefield road between our works and the town of Leeds, and as we have used the properly-shaped broad wheels ever since they were by you brought into use, we can speak with confidence as to the benefits to ourselves of your plans, as contrasted with any other of the numerous roads our teams have to travel over.

You are at liberty to make use of these plain remarks in any way that you may think will best promote the objects you have in view. Feeling it a duty to comply with your request, that we should record our opinions of your labours as well as your Treatise on Road-Management, we cheerfully bear our testimony to the successful results of your efforts, so fully detailed in your excellent work, and we most sincerely co-operate with your views, and feel very glad you are not putting your long and valuable experience on turnpike roads under a bushel. We think if our legislators, as well as all road-makers and road-wearers, were to read and study your Treatise, and adopt your system, we should soon have all our bad roads converted into equally as good roads as those under your care, and the road-debts gradually abolished; whilst thousands upon thousands of pounds sterling would be saved annually in the expense of repairs and horse flesh alone, saying nothing about the increased comfort of all persons using roads, nor the humanity that our poor horses would receive from their owners being so checked as regards the weights allowed, by your plan, to loaden their carts and waggons. In fact, we feel, if you will only persevere in making known your system of road-management, that sooner or later a great change must take place in the public mind; the advantages to mortgagees, road-makers, and users, as well as toll-payers and rate-payers, being so decisive, as to secure adoption as soon as ever properly seen and felt.

We are, Sir, yours most respectfully,

To Mr. R. Bayldon. ROBSON & BUCKTROUT."

Patronized by the Principal Farmers and Graziers in the Kingdom.

CUFF'S FARMER'S FRIEND.

One dose of this invaluable medicine will cure the SCOUR or LOOSENESS in Lambs, Calves, Sheep, Colts, Heifers, Steers, and all Cattle, without leaving costiveness; and given occasionally to Beasts whilst fattening will promote a healthy and thriving condition. It will also perfectly cure the FRET, COLIC or GRIPES in Horses. Price 1s. 8d. or 3s. per Bottle.

CUFF'S FOOT-ROT POWDER

Is a cheap and effectual remedy for the FOOT-ROT or HALT, a single Packet of which will cure One Hundred Sheep, and large Flocks may be soon freed from the Disease by its use. It has been extensively used and highly approved of for nearly thirty years by large Sheep Breeders throughout the Kingdom. Price 1s. per Packet.

CUFF'S FLY, SCAB & MANGE OIL

Will very quickly destroy MAGGOTS in Sheep, and LICE or VERMIN in all animals. It will also cure the MANGE, and SKIN DISEASES in Horses or Cattle, and effectually cleanse a Flock of Sheep from the SCAB or SHAB. Price 1s. 8d. and 3s. per Bottle.

THE BRITISH SHEEP WASH

Is used for Dipping or Dressing Sheep and Lambs, without boiling, to prevent the Fly striking, and the Scab or Shab from spreading, and effectually to destroy TICKS, LICE, and VERMIN in Sheep. Price 2s. 9d., 5s., and 10s. per Jar; or 2s. 6d. per packet.

SHERWOOD'S ORIGINAL DRIFFIELD OILS

Are strongly and confidently recommended for preventing GANGRENE or MORTIFICATION after Lambing or Calving, and for Healing CUTS, STABS, WOUNDS, BRUISES, STRAINS, SWELLINGS, &c., &c.. As these Oils are in constant use by some of the most celebrated Breeders in the world, and have maintained a reputation about fifty years, it would be superfluous to enlarge upon their value and importance. Pints, 2s. 6d., Quarts, 5s.

Prepared by J. H. CUFF, No. 10, Smithfield Market, London, and sold by Druggists and Medicine Vendors

None is Genuine unless signed by J. H. CUFF in writing.

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD: The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; MANN, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROFT, Bury St. Edmunds; DOVE, Swindon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

ELEGANT PERSONAL REQUISITES.

Under the Patronage of and Royal Family the several Sovereigns

Her Majesty "The Queen," of Great Britain, and Courts of Europe,

AND UNIVERSALLY PREFERRED.

ROWLANDS' MACASSAR OIL

Is universally in high repute for its successful results during the last half century in the GROWTH, RESTORATION, and IMPROVEMENT of

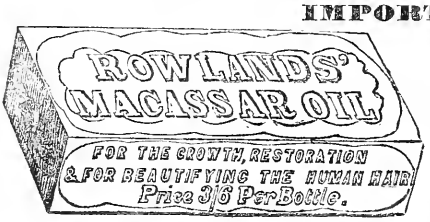
THE HUMAN HAIR.

It prevents Hair from falling off or turning grey, strengthens weak HAIR, cleanses it from Scurf and Dandriff, and makes it BEAUTIFULLY SOFT, CURLY, and GLOSSY.
In the growth of

THE BEARD, WHISKERS, AND MUSTACHIOS

it is unfailing in its stimulative operation. For CHILDREN it is especially recommended as forming the basis of A BEAUTIFUL HEAD OF HAIR.
Price 3s. 6d.; 7s.: Family Bottles, equal to four small, 10s. 6d.; and double that size, 21s.

IMPORTANT CAUTION.



To prevent the substitution of *Spurious Imitations* for the genuine article by unprincipled shopkeepers, A. R. & Sons here add a small copy in *outline* of their Label (as it appears round the bottle) from the burin of Messrs. Perkins, Bacon & Petch, the eminent engravers, of London.

Another portion bears the Signature of the Proprietors, in Red Ink—

"A. ROWLAND AND SONS."

ROWLANDS' KALYDOR,

AN ORIENTAL BOTANICAL PREPARATION

FOR IMPROVING AND BEAUTIFYING THE COMPLEXION AND SKIN.

It eradicates all REDNESS, TAN, PIMPLES, SPOTS, FRECKLES, and DISCOLORATIONS, and renders

THE SKIN SOFT, FAIR, and BLOOMING.

It obviates all the effects of Climate on the Skin, whether with reference to cold and inclemency, or intense solar heat, and affords immediate relief in cases of sunburn, stings of insects, or incidental inflammation. Gentlemen after shaving will appreciate its softening and ameliorating properties.—Price 4s. 6d. and 8s. 6d. per bottle.

CAUTION.—The words Rowlands' Kalydor are on the Wrapper, and their signature, "A. Rowland & Sons," in red ink, at foot.

A GOOD SET OF TEETH

Ever insures favourable impressions, while their preservation is of the utmost importance to every individual, both as regards the general health by the proper mastication of food, and the consequent possession of pure and sweet breath.

ROWLANDS' ODONTO,

OR, PEARL DENTIFRICE,

Compounded of the choicest and most recherché ingredients of the ORIENTAL HERBAL, and of inestimable value in

PRESERVING AND BEAUTIFYING THE TEETH,
IMPARTING A PEARL-LIKE WHITENESS,
STRENGTHENING THE GUMS,
And in rendering

THE BREATH SWEET AND PURE.

CAUTION.—The words Rowlands' Odonto are on the Label, and A. Rowland & Sons, 20, Hatton Garden, on the Government Stamp affixed on each box.—Price 2s. 9d. per box.

Sold by A. ROWLAND & SON, 20, Hatton Garden, London, and by Chemists and Perfumers.

THORLEY'S FOOD FOR CATTLE,

AS USED IN HER MAJESTY'S STABLES,

And also on His Royal Highness the Prince Consort's Farm, Windsor.

IMPORTANT TO EVERY MAN

WHO KEEPS A

THE FIRST AND ONLY PRIZE

EVER AWARDED FOR FOOD FOR CATTLE IN A CONDENSED STATE WAS GIVEN BY

THE CHESHIRE AGRICULTURAL SOCIETY IN 1857,

TO JOSEPH THORLEY, ESQ.,

THE INVENTOR AND SOLE PROPRIETOR OF

THORLEY'S FOOD FOR CATTLE!

THIS FOOD is now receiving patronage from all parts of the kingdom, including His Grace the Duke of Richmond, His Grace the Duke of Athole, the Earl of Wilton, the Earl of Eldon, the Earl of Essex, the Earl of Bessborough, the Earl of Aylesford, the Earl of Lisburne, the Earl Rosslyn, Viscount Strathallan, Viscount Dillon, the Right Hon. Lord Willoughby de Brooke, the Right Hon. Lord Londesborough, Lord Lurgan, Lord Macdonald, Lord Saltoun, Lord Greenock, Lord Hatherton, Lord A. Russell, Sir John Cathcart, Bart., Sir John Ribton, Bart, Sir Wm. Payne Galway, Bart., Sir David Cunynghame, Bart., Sir Montague Cholmely, Bart., Sir John Seymour, Bart., Sir Charles Payne, Bart., Sir Thos. Erskine, the Hon. D. Astley, the Ven. Archdeacon Freer, H. Drummond, Esq., M.P., E. Holland, Esq., M.P., Gerrart Sturt, Esq., M.P., General Wyndham, Col. Ames, Col. Cartwright, Colonel C. Hunter, Lieut.-Col. Caudley, Lieut. Williams, Lieut. and Adjutant Holland, and many others too numerous to mention.

Converts the commonest of Straw into a superior Provender.

It is requisite you should notice the Inventor's Signature on each package or feed, as inferior sorts are often substituted.

BINGLEY HALL CATTLE SHOW, BIRMINGHAM,

30th November, 1857.

Class X.—FIRST PRIZE.

FED ON THORLEY'S FOOD FOR CATTLE.

DEVON STEERS.

See Catalogue, No. 88.—The property of the Right Hon. the Earl of AYLESFORD.

SECOND PRIZE.

FED ON THORLEY'S FOOD FOR CATTLE.

The property of His Royal Highness the PRINCE CONSORT.

The above are a few of the many Prizes obtained through the use of this invaluable Compound, which is adapted for all kinds of Stock, and now in use throughout the world.

Sold in Cases, containing 448 Packages—each Package one feed—at the cost of 56s. per Case; also in Casks, containing 448 feeds, with measure included, price 50s. per Cask. Carriage paid to any Railway Station in the United Kingdom.

None are genuine without the Signature being affixed to each Package or Feed.

Joseph Thorley

INVENTOR AND SOLE PROPRIETOR.

Central Depot.—77, NEWGATE STREET, LONDON.

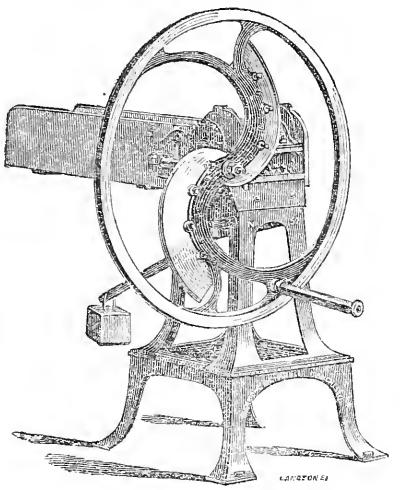
DEVON AND CORNWALL MANURE WORKS,
AND
PATENT STEAM BONE MILLS,
CATTE DOWN, PLYMOUTH.

CHARLES NORRINGTON & CO.'S celebrated SUPERPHOSPHATE OF LIME stands *unrivalled* in the Manure Market for all Root Crops. During the past season upwards of Forty Tons of Mangold Wurtzel, Swedes, and Common Turnips per Acre have been grown with this Superphosphate, without other Manure.

C. N. & Co. bind themselves to the valuation of the various ingredients as given by Professor Way, in the *Journal of the Royal Agricultural Society*, vol. xvi., pp. 532—42.

Price £7 10s. per Ton, in Bags, delivered to any Port in the United Kingdom.

RICHMOND & CHANDLER'S PRIZE CHAFF-CUTTING MACHINES.



UNDER LETTERS PATENT,

NO. 57 NEW PATENT CHAFF CUTTING MACHINE, price £3 15s., delivered at Manchester or Liverpool.

PRESENT PRICES.	£	s.	d.

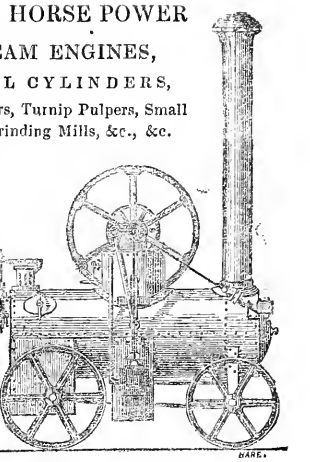
Richmond & Chandler's extensive application of the most approved Steam Machinery in the manufacture of these Implements, afford increased facilities, together with greater mathematical accuracy in every part, obtainable by no other means.

ADDRESS,
RICHMOND & CHANDLER, SALFORD;
BRANCH ESTABLISHMENT,
SOUTH JOHN STREET, LIVERPOOL.

TWO and THREE HORSE POWER
PORTABLE STEAM ENGINES,
WITH VERTICAL CYLINDERS,
For Working Straw Cutters, Turnip Pulpers, Small Thrashing Machines, Grinding Mills, &c., &c.

They will also answer the purpose of a Steaming Apparatus for Steaming Food for Cattle.



PRICE.
TWO-HORSE POWER £65
THREE-HORSE.....£85

Manufactured by
JAMES HAYWOOD, Jn.
PHŒNIX FOUNDRY,
and
ENGINEERING
WORKS, DERBY.

Descriptive Circulars sent free on application.

ESTABLISHED 1812.

TURNIP MANURE. — This valuable fertilizer has been used for the last twelve years with great success by most of the eminent Agriculturists throughout England, and stands unrivalled in the *weight* and *quality* of the bulbs which it produces; it is besides especially beneficial to the *Grain Crops* which follow, while *Clover* is rarely found to fail after the first application. Some of the crops produced by this Manure last year weighed upwards of Thirty Tons per acre. GRASS, BARLEY, CLOVER, and WHEAT MANURES; also BONE, GUANO, and SUPERPHOSPHATE of LIME, warranted of the best quality. Apply to—
H. & T. PROCTOR, Cathay, Bristol.

PROCTOR & RYLAND { Birmingham, Edmonscote, Warwick. And Saltney, near Chester.

N.B.—A Pamphlet on "MANURES, their PROPERTIES and APPLICATION," forwarded on receipt of 12 postage stamps.

IMPORTANT TO FLOCK MASTERS.

COOPER'S SHEEP DIPPING POWDER.

(which has stood the Test of Twelve Seasons)

DESTROYS all the Ticks, stops the Fly, prevents and cures the Scab, promotes the growth of Wool, and improves the appearance and condition of the Flock. For all these purposes this Powder cannot be surpassed, and it positively has no equal as A CURE FOR SCAB, even after all other means have failed, at any season of the year, and however long the disease may have existed in the Flock. Finding there is so little trouble in using this Preparation, which is instantly *Soluble in Cold Water*, Flock Masters patronize it to such an extent, both at Home and Abroad, that Powerful Machinery is required for its manufacture. For Testimonials see Handbills.

Prepared at W. COOPER'S CHEMICAL WORKS, Gt. Berkhampsted, Herts, and sold (with plain directions) at **1s. 4d.** a packet—the average quantity for dipping twenty sheep.

Agents throughout the civilized World, or may be had through any Chemist.

THE ROYAL FARMERS'

AGRICULTURAL AND COMMERCIAL INSURANCE COMPANY.

3, NORFOLK STREET, STRAND, LONDON, W.C.

RATES.

HAIL.—Wheat, Barley, Oats, and other ordinary Crops, without limitation, as to quantity grown. } 6d. per Acre.

The last Bonus (1856) was upwards of 66 per Cent. to Insurers of the four previous years, and in proportion to Insurers for a less period.

The Royal Farmers' is the first Office which introduced this additional means of protecting the interest of the Farmers.

It should be borne in mind that no care whatever can prevent damage by Hail, and that there is no means of protection other than that now offered.

The losses by Hail Storms within the last few years in districts where parties neglected to insure, have been very severe; and many persons were reduced from prosperous circumstances to the painful necessity of availing themselves of a public subscription—a necessity they might have avoided by the trifling payment of Sixpence per Acre.

FIRE.—Fire Insurances of every description at moderate rates. Farming Stock without average, 4s. per cent.

LOSSES paid immediately after the amounts have been ascertained.

LIFE.—Life Insurances on moderate terms by Policies payable to the Registered Holders.

Further particulars may be had at the Chief Office, or of the Agents.

ADDITIONAL AGENTS WANTED. Application to JOHN REDDISH, Secretary and Actuary.

CARSON'S

ORIGINAL ANTI-CORROSION PAINT,

Specially patronized by the British and other Governments, the Hon. East India Company, the principal Dock Companies, and other public bodies, &c., is particularly recommended to the Nobility, Gentry, Agriculturists, Manufacturers, West India Proprietors, and others, it having been proved by the practical test of more than seventy years to surpass all other paints as an out-door preservative. It is extensively used for the protection of wooden houses, farm, and other out-buildings, farming implements, conservatories, park paling, gates, iron railings, iron hurdles, copper, lead, brick, stone, old compo, and stucco fronts, and tiles to represent slating. The superiority of the Anti-Corrosion to every other paint for out-door purposes may be easily inferred from the simple fact, that its use has been always most strenuously opposed by Colour Manufacturers, Painters, Oil and Colourmen, and others interested in the sale of common paints. It is also very economical, any labourer being able to lay it on.

COLORS:

White Stone	34s. per cwt.	Dark Chocolate	30s. per cwt.
Light Do.		Bright and Dark Red	
Drab or Portland Do.		Copper	
Bath Do.		Black	
Light Yellow Do.		Invisible Green	46s. per cwt.
Dark Yellow Do.		Deep Green	56s. „
Light and Dark Oak		Bright Green	56s. „
Brown	30s. per cwt.	Blue (for Carts and Wagons)	56s. „
Light and Dark Lead			
Light Chocolate			

In casks of 28, 56, and 112 lbs. each, and upwards.—OIL & BRUSHES.—The Original Anti-Corrosion Paint is only to be obtained of

WALTER CARSON & SON,

(Successors to the Inventors)

9, GREAT WINCHESTER STREET, OLD BROAD ST. (NEAR THE ROYAL EXCHANGE) LONDON, EC.

who will show 700 most flattering Testimonials received from the Nobility, Gentry, and Clergy, who have used the Anti-Corrosion for many years at their country seats.

A Copy of the Testimonials will be sent on application,

No Agents.—All Orders are particularly requested to be sent direct.

FRAMPTON'S PILL OF HEALTH. Price 1s. 1½d. and 2s. 9d. per box.—This excellent Family Pill is a medicine of long-tried efficacy for purifying the blood, so very essential for the foundation of good health, and correcting all Disorders of the Stomach and Bowels. Two or three doses will convince the afflicted of its salutary effects. The stomach will speedily regain its strength; a healthy action of the liver, bowels, and kidneys will rapidly take place, and renewed health will be the quick result of taking this medicine, according to the directions accompanying each box. PERSONS of a FULL HABIT, who are subject to headache, giddiness, drowsiness, and singing in the ears, arising from too great flow of blood to the head, should never be without them, as many dangerous symptoms will be entirely carried off by their timely use. The following extract of a letter from Mr. Thomas Province, of Winchmore Hill, Middlesex, is another proof of the Invaluable Medicinal Properties of FRAMPTON'S PILL OF HEALTH:—"For upwards of nine years I have experienced the efficacy of this excellent medicine. I had long previously been afflicted with headache and indigestion, but a friend having induced me to make a trial of Frampton's Pills, I now inform you that a few doses gave me great relief; and during this long period of time I have taken them in preference to any other medicine; and I have the happiness of saying that I never had a better state of health, which I attribute to Frampton's Pills. I beg further to add, that this medicine is in general use by my family, and we know of nothing to equal it." FOR FEMALES these pills are truly excellent, removing all obstructions, the distressing headache so very prevalent with the sex, depression of spirits, dulness of sight, nervous affections, blotches, pimples, and sallowness of the skin, and give a healthy, juvenile bloom to the complexion. To MOTHERS they are confidently recommended as the best medicine that can be taken; and for children of all ages they are unequalled. These Pills unite the recommendation of a mild operation with the most successful effect, and for elderly people, or where an occasional aperient is required, nothing can be better adapted. In consequence of the great and increasing demand, the Proprietor has obtained permission from her Majesty's Commissioners to have the name and address of "Thomas Prout, 229, Strand, London," impressed upon the Government stamp affixed to each box. Sold by all Vendors of Medicine.

PRICE ONE SHILLING EACH.

NEATLY PRINTED IN FOOLSCAP OCTAVO, EACH VOLUME CONTAINING FROM 130 TO 160 PAGES OF LETTERPRESS,

PLATE I.

PORTRAIT OF J. J. FARQUHARSON, ESQ.

ENGRAVED BY J. B. HUNT, FROM A PHOTOGRAPH.

PLATE II.

A HEREFORD PRIZE OX.

THE PROPERTY OF MR. JOHN SHAW, OF HUNSBURY HILL, NORTHAMTON.

J. J. FARQUHARSON, ESQ.

This great Dorsetshire agriculturist and worthy country gentleman first saw the light on October 9th, 1784. Oxford claimed him in due course, and he passed his undergraduate days pleasantly enough, beneath the sound of "Mighty Tom" of Christ Church. Treadwell was but a lad of six, playing about among the hedgerows of Stoke Talmage, when his future master flung aside his Herodotus for his Somerville, and commenced at two-and-twenty, with a goodly band of whitecollars, as huntsman to his own pack. It was the English country squire at once taking to the business of his vocation.

Unlike many men, he did not begin with harriers, or a three or four-days-a-week pack, but boldly flung himself at once into the fox-hunting breach, and hunted, at his own expense, all Dorsetshire and part of Somersetshire six days a-week from the very outset, with thirty horses, two kennels, and ninety couple of hounds. Cranbourne Chase, with its short oaks and hazel trees, was then, as it is now (though it was rather short last season), the great nursery of Dorsetshire foxes; but its yellow-breasted martens, to whose memory English historians still continue to cling, as the latest relics of the vermin of feudal times, have all but disappeared, along with the badgers in Wychwood Forest.

In addition to his extensive agricultural pursuits, among which sheep-breeding is not the least, Mr. Farquharson has always been an enthusiastic breeder of horses, and his colours were once perpetually seen in front at the county races. The Hobgoblin strain, which goes through Annette back to Phantom, has been his choicest blood of late years, and it has crossed especially well with that of an Elis mare, who died about two years since, leaving two rare chesnuts—one of them Will-o'-the-Wisp—as her legacy to the stud. It is upon The Pony, who is by Cadiz, and quite as tender as a lover with hounds, that Treadwell will go down to posterity in Grant's picture, while his good master selected Botanist to honour.

It was no small sorrow to the white-collars and farmers of Dorsetshire that "The Squire" should have been prevented, by a severe horse-kick, from hunting with them the last five weeks of the season; and until he "pronounced the words of doom" at

the farewell festival in February, they clung to the hope that the parting was not to be. We care not to dwell on this sad wrench and its causes. There have been heart-burnings enough, and the division of the country has indeed been purchased at a bitter price. Dorsetshire has not, however, failed to show its gratitude. In 1827 it presented its Squire, at a cost of eleven hundred and fifty guineas, with a vase and shield, as a meet acknowledgment of his chivalry; and thirty years later it celebrated his jubilee, by the presentation of two candelabra in the *renaissance* style. The picture, to which the greater portion of the £1800 then collected was devoted, was not finished till many months after, and then it merely came to grace the farewell banquet.

From none on this occasion did the cheers come more heartily, or was the expression of sympathy more manifest, than with the farmers of the county. It is, indeed, as a good landlord and excellent country gentleman that we here give our greeting to Mr. Farquharson. Although the chase may have been his first love, he has ever shown an innate and lasting inclination for agricultural pursuits. He farms himself still, we believe, between two and three thousand acres of land in the best possible style. The character of his flock has long been famous, and he ranks as a successful exhibitor at our agricultural meetings. He is of course a member of the Royal Agricultural Society, and with such-like support the cause will ever prosper.

PLATE II.

A HEREFORD PRIZE OX.

THE PROPERTY OF MR. JOHN SHAW, OF HUNSBURY HILL, NORTHAMPTON.

This capital beast was bred by Mr. Richard Shirley, of Bawcott, Munslow, Shropshire.

At the Leicestershire Agricultural Society's Show, in December, 1856, he took the first prize of 15 sovs.

At the Rugby and Dunchurch Show, in November, 1857, he took another first prize of 15 sovs., open to all England.

At the Birmingham and Midland Counties Show, December, 1857, he took the first prize of 10 sovs. as the best of his class, the extra prize of 20 sovs. as the best of all the Herefords, and the GOLD MEDAL as the best ox in the yard. Mr. Shirley also received a Silver Medal as his breeder.

At the Smithfield Club Show, the week following, he took the first prize of 25 sovs., Mr. Shirley having another Silver Medal. The ox was purchased here by Mr. Gutheridge, of High-street, Poplar.

This was a magnificent beast, of immense length and depth, with all the good points of the Hereford beautifully developed. He had a wonderfully fine head, with good back and fore-quarter; was very heavy, and of excellent quality. Indeed, had it not been for a little dip in the back, he might have been passed as perfect. His feeder, Mr. Shaw, is a new man as an exhibitor, at least of cattle; his entries at the more important meetings having so far been confined to the sheep classes. It is needless to say this Hereford did every credit both to his judgment and management.

DRESSINGS FOR THE TURNIP CROP.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

The different manures employed for the turnip crop are of annually increasing interest. Considerable public discussions have recently been held upon a theme so important to the stock farmer. When this paper comes before the agriculturist, turnip sowing will be about to commence in most portions of our island, and few are the farmers so happily situated as not to be benefited by the application of artificial dressings. At such a season, then, it will surely be attended with benefit if we inquire into the comparative merits of some of the manures which are urged upon the farmer's attention for the use of his root crops.

In the first place, then, let us refresh our memories by examining the mineral matters which the turnip crop requires for its healthy growth; what the perfect plant invariably contains; what it absorbs from, and gradually exhausts the soil of. This analysis was, some little time since, made by Way (*Jour. Roy. Ag. Soc.* vol. viii., p. 199.) He has

given the amount of mineral matter contained in one ton of the entire plants, bulbs and tops, of the common turnip. It is as follows:—

Silica	0·34
Phosphoric acid ..	1·77
Sulphuric acid ..	2·33
Lime	1·76
Magnesia	0 47
Peroxide of iron ..	0·07
Potash	6·07
Soda	1·46
Common salt ..	1·49

The amount of the mineral and organic matters of the turnip plant varies, however, in different seasons and climates. This fact has been to some extent ascertained by Professor Anderson and Mr. J. B. Lawes. The Professor examined the composition of turnips grown in the same season from the same seed, in Argyleshire and in Warwickshire (*Trans. High. Soc.*, 1856, p. 420); and although his trials are by no means conclusive in themselves, yet they well serve to indicate the importance of continued experiments. They illustrate, remarks the Professor, one of the great difficulties with which we have to contend in such inquiries, for we know nothing precise regarding the climate of these counties, further than that Argyleshire is characterized by the abundance of rain during the summer and autumn months, and by a low summer temperature; while Warwickshire has as favourable a climate as any English county. The turnips analyzed were swedes and yellows, both grown from the same seed in each locality, and treated in a precisely similar manner. The following were the results per cent.:—

	Warwick.	Argyle.
SWEDES.		
Water	93.39	95.22
Ash	.50	.50
Protein compounds ..	.75	.44
Other constituents ..	5.36	3.84
	100.00	100.00
Nitrogen	.12	.07
Phosphates in the ash ..	.09	.06
YELLOW.		
Water	94.11	95.35
Ash	.70	.72
Protein compounds ..	.62	.50
Other constituents ..	4.57	3.43
	100.00	100.00
Nitrogen	.10	.08
Phosphates in the ash ..	.09	.05

Comparing these analyses, adds the Professor, it is at once seen that the turnips grown in Warwickshire materially exceed in value those from Argyleshire. The swedes from Argyleshire contain 2 per cent. more water than the Warwickshire swedes; 10,000 parts of the Warwickshire swedes contain 661 parts of solid matters, while the same quantity of those from Argyle contain only 440. If we assume the amount of solid matters as the measure of the nutritive value of the two samples, then it would follow that two tons of the Warwickshire swedes must be equal to nearly three tons of the Argyleshire, and it is probable that this is not far from the truth.

The trials of Mr. Lawes were carried on in his usually extensive and elaborate manner, at Rothamsted, in Hertfordshire, and were chiefly directed to the question of the influence of the amount of rainfall, and the mean temperature of the turnip season, upon the produce of the crop. In his trials in the years 1844 and 1845, he obtained the following results:—

	1844.	1845.
The mean temperature from June to end of Oct.—turnip season	59.4	57.8
No. of days on which rain fell during this season	67	74
Inches of rain falling	10.37	9.62
Produce of bulbs per acre in tons and cwts.:		
Manured with 12 tons of farmyard dung	10 15	7 14
Do. with superphosphate of lime	7 14	12 13

As a general fact, it is evident, concludes Mr. Lawes, that the amount of the produce of the turnip is very materially dependent upon the climatic character of the season, not only as in itself a *resource*, but as an *essential agent* in the appropriative power of the plant, however liberal and complete may be the supply of constituents within the soil.

To promote the growth of the turnip crop by supplying its mineral and organic substances, two valuable manures—guano and superphosphate of lime—have been extensively used, and with very remarkable success. The employment of these powerful fertilizers, however, has been found to require considerable care in their application to the soil, and moreover that the result of the trial is materially influenced by different climates and soils. On the fine loamy barley lands of Surrey resting upon the chalk, a *mixture* of these two manures is commonly used—say, 1 cwt. of guano and 3 cwt. of superphosphate of lime per acre. This proportion of the superphosphate employed has been gradually increasing for the last two or three seasons. We have found, in fact, that in my neighbourhood better crops are thus produced, and moreover that the good effects of the superphosphate of lime, applied as a dressing to a root crop, are commonly very plainly discernible in the succeeding barley crop, and not unfrequently even in the third or clover crop. It is a common and a good practice with my neighbours, in Surrey, to drill these manures, either by separate coulters

below the seed, or else (especially when the turnips are grown on the ridge) to mix them with a considerable proportion of dry ashes, and spread them on the soil before the last ploughing.

That a mixture of guano and superphosphate of lime is a far preferable dressing for turnips, than either of these valuable fertilizers applied alone, seems to have been the result of many careful trials made in other and widely different localities: take, for instance, two series of trials lately made in Scotland and in Ireland. In those in Scotland (*Quar. Jour. Ag.* 1857, p. 667), in one trial the whole field was manured with 20 tons of farm-yard compost per imperial acre, and then dressed with the following manures, at a cost of 26s. 6d. per acre. The results were, that on equal-sized ridges—

Dissolved bones and Peruvian guano	gave	6	tons	2	cwt.
Steamed bones and guano..	„	6	„	3	„
Steamed bones and guano..	„	6	„	1	„
Dissolved bones alone	„	6	„	7	„
Dissolved bones alone	„	5	„	17¾	„
Steamed bones alone	„	5	„	19	„
Leone guano alone	„	4	„	7	„
Leone and Peruvian guano	„	5	„	12	„

In another trial, at Borgue—

	Tons.	cwts.	
Peruvian guano, 5 cwt. per acre, produced of bulbs	20	12	per acre.
Bolivian ditto, 5 do.	19	15	„
Blood manure, 7½ do., do.	18	5	„
Dissolved bones, 7½ do., do.	17	15	„

In some experiments made by Mr. Templeton, at Clanboye, in Downshire (*Irish Farm. Gaz.*), with Skirving's purple-top swede, he found that the turnips from 24 tons of farm-yard manure per acre produced the greatest weight of bulbs per acre; those from 12 tons of manure and 2½ cwt of Peruvian guano the next greatest weight; those from 12 tons of manure and 12 bushels of crushed bones the next best; those from 5 cwt. of Peruvian guano the lowest weight of all.

It has been the practice with many farmers to mix the Peruvian guano with an equal weight of common salt: this would seem to be especially a useful addition to Peruvian guano, as a dressing for mangel wurzel, and for its after-effects on the barley crop.

It is, of course, of the first importance to procure the best Peruvian guano and superphosphate, and I would earnestly warn my readers to be very cautious in the use of any other. Professor Cameron, in his valuable work on "The Chemistry of Agriculture," p. 113, has given the analyses of several varieties of guano known in commerce. Let us only contrast the average composition of the Upper Peruvian guano, with that from the Kooria Mooria Islands, which last variety I fear is likely to prove of little average value :—

	Peruvian.	Kooria Mooria.
Water	10.00	18.10
Organic matter	21.68	12.41
Yielding ammonia	(4.50)	(2.05)
Earthy phosphates.....	51.50	42.67
Carbonate of lime	—	4.19
Alkaline salts	14.12	4.13
Sand, clay, and other useless matter	2.70	18.50

Of the adulterated (and of course always the *dearest*) guanoes, and their names and varieties are legion, Professor Cameron too truly tells us that the substances with which guano is adulterated are sand, clay, powdered bricks, marl, chalk, limestone, salt, &c., one or more of these being added to the guano, very commonly to the strong-smelling Ichaboe or damaged Peruvian, the proportion of course depending not only upon the conscience of the compounder, but on the presumed gullibility of the purchaser. So skilfully are these compounds prepared, that the most experienced buyers are often imposed upon, detection in very many cases being very difficult by any except chemical means. Several analyses of adulterated Peruvian guano were during the past month communicated by Professor Voelcker to the Royal Agricultural Society, see our present number, page 521.

The same systematic frauds are carried on in the adulteration of superphosphate of lime. In this case the matter added is very commonly finely-ground coprolites and some cheap salt, such as sulphate of soda or common salt. There is only one safe way of being secure from these robbers. Let the farmer deal only with those makers—and there are more than two or three such—who have been long-established, and whose characters are above suspicion. If the intending purchaser is still in doubt, let him ask the opinion of such men as Anthony Gibbs and Sons, Professors Way, Voelcker, Anderson, Wilson, &c. Let the reader submit to one of these gentlemen a list of makers, and ask him to put a mark to the names of those whom the marker knows to be trustworthy, and then he may purchase with comfort.

There is certainly a very general growing feeling in favour of superphosphate of lime as a dressing for turnips. The editor of the *Quarterly Journal of Agriculture*, from the result of Scotch experience, also inclines to this opinion. After observing (volume for 1858, p. 322) that for some years the Caledonian farmers have been profitably trusting to Peruvian guano, he adds, that it has been found, however, that the white crops on those fields on which there has been a recent and several applications of guano are soft in the straw, and do not yield according to bulk as well as they used to do. (This softness of straw, however, has in my expe-

rience been readily prevented by the addition to the guano of at least an equal bulk of common salt.) In Bavaria, we find from the same authority, the farmers, after using guano for some years, now find it necessary to apply it in larger quantities than formerly, in order to obtain the same results; and, from some calculations of the comparative cost of the production of turnips in Scotland, it resulted "that the average cost of a ton of turnips from guano in six distinct experiments, in different parts of the country, was 3s. 2¼d., while the cost of a ton from superphosphates (made by different manufacturers), in four districts, is 2s. 2¾d., the cost of the manure in both cases only being calculated; so that there is a difference of 11½d. per ton in favour of superphosphates; and as the average crop of the experiments was about 25 tons per acre, we have a profit of £1 4s. per acre by using superphosphates instead of guano.

The reason why the soil gets "tired" of certain crops and fertilizers is well worthy of still more extended examinations than it has yet received. The land "tires" we all know of clover. Many farmers will tell you that their soils are getting more and more tired of swedes, in spite, too, of all the artificial dressings which they so generously bestow upon them. Hence one reason amongst several why mangel is so increasingly cultivated. Let these little difficulties inspire us with fresh ardour for more careful researches. There is probably something extracted from the soil by particular plants, which, although of importance to the growth of the crop, is yet too minute to have been yet detected. Certain predatory insects, too (some, perchance, yet unknown to us, of a very minute yet pernicious character), follow all crops, gradually extending themselves to the farmer's loss, and no crop has been more subject to these than the turnip. In arriving, however, at such a conclusion, let us not forget that the cultivation of no crop has been more extensively aided by science. If the chemist had done nothing for agriculture than discovering the use of superphosphate of lime, he would even then have been well entitled to the cultivator's gratitude.

BARLEY.

In Scotland, there has not been the same attention bestowed in selecting and propagating new varieties of barley and bere as of wheat and of oats, nor has the introduction of varieties from other countries been generally successful. Hence, the kinds in cultivation are limited in number, and none of these are comparatively newly propagated varieties. To explain this apparent indifference on the part of the growers of barley is impossible. Perhaps the prevalence of the belief that barley is not generally so profitable a crop as wheat or oats, except where the soil and climate are highly suitable, may account in part for the apathy displayed. Whatever is the cause, the consequence is the cultivation of a restricted number of kinds of barley and bere.

Barley is cultivated mainly for the production of ales and alcohol; but a considerable quantity is manufactured into pot-barley, Ulm-barley, and a limited portion is ground into meal for bread, and also for feeding stock. The light and inferior samples are principally used for feeding horses, being generally prepared by boiling.

Barley was at one time in more general cultivation than at present. Up to the beginning of the present century, it occupied in part the place now occupied by wheat, being then grown extensively as a bread corn for the manufacturing of meal, besides being made into pot-barley, Ulm-barley, and for furnishing grain from which the extracts ales and alcohol were obtained. The bread from barley-meal was baked into scones — "supple scones"—resembling those made of wheaten flour. Sometimes mashed potatoes were mixed with the meal—rarely wheaten flour. This kind of bread was mainly confined to the western side of Scotland, but there oaten cakes formed the staple bread. Mashlam bread—a mixture of barley and legumes —was also in partial use over Scotland and the north of England; but in the south-eastern counties this was the principal bread of the working classes, barley being mixed with beans and peas—generally in the proportion of two bushels of the former to one of the latter. From this were baked what is usually known as gray bannocks. These were usually above one inch in thickness, and were seldom palatable to one unaccustomed to the bread, except when a little soda was used to render the bread lighter. On special occasions, such as Hansel Monday, and sometimes on the occurrence of an addition to the hind's family, a portion of wheat was substituted for the barley, in part or whole, along with the mixture of beans and peas—the legumes being generally grown as a mixture for a field crop. A taste for wheaten bread (white bread) became general in the family of the hinds about thirty years ago, but such an innovation was generally regarded as wasteful extravagance, and bakers' bread was rather covertly partaken of, until within the last few years.

The occurrence of low prices for wheat, simultaneous with the operation of a free tariff, rapidly extended the use of wheaten bread; which is now taking the place of gray-bannocks—wheat being substituted for barley in preparing the meal. From time immemorial, in the districts referred to, the wages (gains) of the hinds have been paid in kind — the bread corn being generally eighteen bushels of barley, and eight bushels of beans and peas; the oats, raised from forty-eight to sixty

bushels about the beginning of the present century, being partly manufactured into meal for porridge, and partly sold. From the change in the habits of the people, it is a question for the employers and employed to consider whether it would not be a mutual advantage to both to substitute wheat in part or in whole for the barley.

With advancing agriculture, the period of sowing barley has become much earlier than formerly. During the first quarter of the present century, the sowing of barley seldom commenced before the last week of April, ending with the first week of June, Indeed, "here seed time," as it was then called, was betwixt the Terms—15th to 26th May. In the south-eastern counties barley was usually taken after the turnip crop, especially where the land was not cleared of the turnips previous to winter. The period of sowing was usually the end of April. Barley thus occupied the second place in the rotation, this being a four, five, or six course. In the Carse districts where barley occupied the fourth place in the six-course rotation, the land received a spring fallowing—three spring furrows, with the necessary harrowing and rolling to pulverize the soil for the reception of the seed. Sowing proceeded during the month of May. With the extension of thorough draining the land is now earlier seeded over the whole of Scotland, although in backward districts, the practice of the beginning of the century is still followed. The general advance in the period of sowing is fully one month, in some districts about six weeks. A considerable breadth of barley is now grown after a cereal crop —wheat or oats. Manure is usually applied. When barley is taken after wheat, grass seeds—a mixture of ryegrass and clovers—are sometimes sown with the barley. By this practice the four-course rotation is rendered a five-course. Where barley is taken after the oat crop, portable manures are applied—generally Peruvian guano. Growing two white crops successionally is a partial return to the general practice of the last century, and is by many regarded as a breach of the rules of good husbandry. It must not be assumed from this, however, that the practice is not good husbandry, especially when the barley is taken after the oat crop, and is followed by a green crop. The facilities afforded for the maintaining fertility by the application of portable manures renders the practice judicious; especially as, by increasing the number of crops in the rotation, potatoes, turnips, and clovers can be grown with more uniform success, than where these are repeated at shorter intervals, and where partial failures have frequently occurred. Local position, soil, and climate are the principal elements in judging of the practice, which gives a larger money return, both for the value of the crops, and their being grown more healthy, while the fertility of the soil is maintained.

None of the kinds grown in Scotland are what are classed as winter barleys, although in many situations several varieties would survive during winter. An experiment with the Chevalier variety in East Lothian—sowing it in the month of October—has proved successful, the crop ripening nearly a month earlier than when sown in spring, and producing a very fine sample. The periods during which barley occupies the ground, vary with the variety, character of the soil, and season. The period of sowing now extends from the first of March to the first week in June—the latter being very exceptional. Period of reaping extends from the beginning of August up to the middle or even end of October. The more early kinds ripen about ten to fifteen days before the later kinds, but the sowing of the late varieties is confined to the months of March and April, so that the barley crop is usually reaped in the beginning of harvest.

The aggregate produce of barley has been greatly increased by the appliances of draining and portable manures. By the agency of these, barley is now grown on all kinds of soils where the climate is favourable, while on all soils the produce is much more uniform, and the average quality very much improved. Phosphatic manures act powerfully as fertilizers for the growth of barley, but nitrogenous manures exercise a power which is most striking. Nitrate of soda applied in small quantities greatly increases the produce of grain; but it is by the action of Peruvian guano, furnishing both nitrogen and phosphates, that the produce of this cereal can be most largely increased. Various estimates have been made as to the increase of produce which is due to the action of furrow-draining, and to the fertilizing agency of portable manures. The increase from furrow-draining has been estimated at one quarter per acre, and from the use of portable manures from four to six bushels. The increase from the two agencies combined cannot be estimated at less than ten bushels per acre. The introduction of Chevalier barley has also increased the aggregate produce. In East Lothian, for instance, where the three causes are in operation, the acreable produce is upwards of 40 bushels; and on some farms, the produce of which we have an opportunity of knowing, from records carefully kept, and which embrace a considerable period, the average acreable produce of barley has increased sixteen bushels per Scotch acre within the last twenty years.

At one time great attention was bestowed on the changing of seed, particularly from the coast to the interior. Ware barley—that is, barley raised on farms where seaweed was applied, always commanded a high price in spring. Barley raised on Carse soils was also in demand for seed. In upland districts, the crop was often injured from frost, consequently was unsuitable for seed; but there appear to have been other influencing causes which led to this general belief. The desire to secure a change of seed is not now general; indeed, in some districts, is almost in abeyance. That there are well-ascertained facts as to the beneficial effects of a change of seed is undoubted; but where the condition of the land is maintained, and the crops properly ripened, the necessity of a change of seed may be doubted. On one farm in Mid-Lothian, the same barley has been raised without change for forty years, and in favourable seasons this grain has reached the extreme weight of 60 lbs. per bushel.

Common bere or bigg is now cultivated chiefly in the Highlands and Western Islands: also to a limited extent in upland districts, where the situation or

soil is unsuitable for the growth of common barley. On light and peaty soils bere succeeds better than barley, being less injured by lodging. It is generally taken after a potato crop, or on peaty soils recently reclaimed, following the green crop which succeeds the oat crops.

The cultivation of bere is being gradually more and more restricted, chiefly from the lower price at which it sells, compared with barley of equal weight. At one time bere was in much more general culture; even in the best parishes in the Lothians, rents payable in kind, and the stipends of the clergy, were payable in bere. It was usually considered that land somewhat out of condition for barley produced a more certain crop of bere. From the terms barley and bere being frequently used synonymously, there is considerable difficulty in following writers of the last century as to what was the kind of grain referred to.

The kinds generally grown in Scotland are what are usually termed "common bere"—straw seldom over 3 feet in length; colour, when ripe, a buff yellow—ear about 2 inches long—the grains clustering, uniform and closely set—the length of awns about two to three inches, these bristling outwards, and adhering with consideable force to the grain. The grains are pointed and taper towards the ends. This distingushes bere from common barley. The colour of the grain is a dingy brown—weight seldom 54 lbs. the bushel; more frequently from 40 to 51 lbs. Produce varies much—from 3 up to 8 qrs. per acre, but is, on certain soils, more uniform in yield than commonly barley, and ripens from four to ten days earlier.

Victoria bere is a selected variety, larger and stiffer in the straw; the yield is stated also to be greater. This variety is coming into more general favour.

Peruvian barley is a bere—colour of grain black or dark blue--grains larger than the common barley, and clustering like common bere—awns long and dark coloured, adhering to the grain; length of straw ranges from 3 to 4 feet. When sown early, and on rich soils, this variety is prolific, nearly equalling that of Chevalier barley. But there exists a strong prejudice against it, both by millers and maltsters, from the colour of the grain. The name Peruvian indicates that it was imported from Peru; but it is similar in character to the black winter barley of the continent, and may be regarded as identical. Beyond experiments, this variety has never found a place, and is now all but neglected.

Common Scotch barley has been cultivated from time immemorial. It seems to be identical with common English barley. There appear to be several kinds, some being more prolific than others. These sub-varieties are probably in part the result of selection, but more generally of continued cultivation on fertile soils. One of the best of these is Bell's. Other names are in use—Stirlingshire, &c. The straw of the common barley is generally about 3½ feet in length, small in the pen, leaf narrow, deficient in strength, and liable to lodge—especially on soils in high condition, with an excess of carbonaceous matter. The grain is two-rowed; the number of grains in the ear generally under twenty-eight; awns extend about 3 inches; when well ripened, readily parts with the awns; the grain is less pointed than bere; colour a buff yellow; in very dry seasons, the colour has a tendency to a bright golden tinge. Weight of grain from 50 to 56 lbs. the bushel; average about 53 lbs. Produce is very unequal, being more influenced by the character of the season than any other variety; average produce 3½ qrs.—extreme produce 7 qrs. It occupies a greater breadth than any of the other varieties, mainly from its earliness, and also from its admitting more air to the soil—thus fostering the growth of grass seeds—these being usually sown with the barley crop. In the best-farmed districts, however, common barley, from its softness of straw—thus being more liable to lodge from wet during the period of growth, and, from sprouting much more rapidly when the grain is in the stook—has generally given place to Chevalier with its sub-varieties. The weight of straw per acre seldom exceeds a ton and a-half per acre—average little over one ton.

Chevalier takes the name from the propagator, a gentleman in the south of England; introduced into Scotland about 1835, and rapidly came into general favour. Experiments undertaken at its introduction into East Lothian usually gave an increase of produce over common barley of 6 to 8 bushels per acre, with an increased weight of grain per bushel of from 1 to 2 lbs. On some farms where the situation is not so favourable for the growth of barley, it is stated that the yield does not exceed that of common barley. Chevalier is generally of a luxuriant growth; straw about 4 feet in length, pen of greater diameter and stoutness than the common barley, leaf broader. Weight of straw sometimes exceeds two tons per acre—average weight about one and a-half tons; readily eaten by stock, particularly by horses. The ears resemble common barley. Number of grains generally under thirty; grain rounder and more plump. Sample otherwise generally superior to common barley, especially when the grain has been early sown, and the season favourable. Period of ripening from eight to ten days behind common barley, and therefore generally sown in March, or latest by the middle of April. Weight of grain from 53 to 58 lbs. per bushel; 60 lbs. have been grown, but this is very exceptional. In the best barley districts of Scotland the average weight, when well dressed, varies from 54 to 57lbs. Produce per acre from three and a-half quarters up to nine quarter—in one or two cases this latter quantity has been exceeded. The produce is more uniform than common barley, besides being larger. The variety is not suitable for late and exposed districts, the ears being liable to break off during storms in harvest; when the crop is allowed to become too ripe, the stalk is bent close to the ear, and the weight of the ear occasionally breaks the straw. There also exists a prejudice, especially in Carse districts, where there is a tendency to a luxuriant tillering and growth in the straw, that the closeness of the crop injures the braird of grass seeds. In the Lothians, however, it is preferred, on account of the stiffness of straw, rendering it less liable to lodge, and thus destroy the grass seeds. It also withstands a wet harvest better then the

other varieties; besides, the straw of the Chevalier is very superior. A common error on high-farmed land where grass seeds are sown is the allowing of too much seed. The quantity should not exceed, for broadcast, nine pecks per acre. Next to common barley, Chevalier occupies the largest breadth, and is gradually extending from the best-cultivated districts into the most backward.

Annat barley—selected in Perthsire in 1830 by the late Mr. A. Gorrie. The straw is about the same length and strength as the Chevalier, with a tendency to a purple tinge, particularly at the joints; grain, round and plump, like the Chevalier —of a bright yellow colour. The weight of bushel, with produce, similar to those of the Chevalier. Some growers have found this variety more delicate than the Chevalier, and abandoned its cultivation on this account. Annat barley occupies the third place.

Western barley—evidently a variety of the Chevalier, introduced into East-Lothian shortly after the Chevalier. It is now little cultivated.

Italian barley.—The straw long and of a bright golden colour; ears shorter than the Chevalier, with the grains more compact and pointed outwards. This, also a two-rowed variety, yields a large plump grain of a bright light yellow colour. It is somewhat later than the Chevalier; its cultivation has not extended, and is now much restricted; it is generally known by the term "golden barley." It does not succeed well in cold wet seasons.

Silesian barley.—A variety introduced into Leith from Silesia about 18 years ago; is in partial cultivation in the neighbourhood of Edinburgh: straw shorter than the Chevalier, bearing a close resemblance to common Scotch barley, the weight per bushel rather exceeding that of common barley; grain somewhat long in form; colour a dark shade of yellow. It is stated to be prolific, and better adapted for late districts than the Chevalier. It has been successfully grown at 800 or 900 feet above the level of the sea, and yielded 8 qrs. per acre, of good weight.

Saale barley—Introduced 18 years ago. A beautiful clear-skinned, small-grained variety; did not generally answer expectation; but occasionally fair crops have been raised.

Lincoln barley. — Introduced about 30 years ago; was found to produce long straw, with a fine-formed ear; period of ripening, about fourteen days behind common barley; its cultivation was dropped mainly from lateness of ripening. The quality of the grain also appeared to deteriorate when grown in Scotland.

Norfolk barley. — A variety of English called white Norfolk was very much grown in some parts of the Lothians before the introduction of Chevalier; by continued cultivation it lost its distinguishing characteristics, and latterly it did not push the ear fully out of the shot-blade. It was in request with the maltsters when first introduced.

Naked barley has been experimented with; but from the general dislike to this variety by maltsters, it is now seldom met with. Two varieties have been experimented with — one termed Siberian, the other Nepaul. Both appear to be the same variety, and stated to be in cultivation in the Himalayas, where sometimes two crops are grown in a season.—North British Agriculturist.

THE ADVANTAGE OF AUTUMN CULTIVATION FOR ROOT CROPS.

WINFRITH FARMERS' CLUB.

The monthly meeting of the members of this club was held at the Bear Inn, Wool, on the last Wednesday in March, the subject being "Autumn Cleaning of Stubbles."

Mr. DARBY, of Lytchett, said he thought the subject which he had the honour of introducing to to their notice that evening was of the very greatest importance. They all knew very well that good and proper cultivation of the land ranked the very highest, and always had ranked the highest, of all agricultural questions. In fact, the ancient writers told them how high it was in the estimation of the Romans. When one of them was asked what was the first principle in farming, he replied, "Arare"—that is, to plough; and when asked what was the second, his answer was the same, "Arare." Dr. Lyon Playfair, in his admirable essay on cultivation, in "Morton's Encyclopædia," placed in a like prominent position the proper working of the land. He states that the main conditions of cultivation required to be fulfilled are—first, a thorough pulverization and drainage of the soil; second, a progressive chemical disintegration or liberation of insoluble ingredients; and third, a renewal, by means of manure, of those substances which have been removed from the soil by successive crops. They would perceive that he placed good manuring last, after good cultivation. They all knew, however, that it was necessary for both to go hand in hand; but in a great variety of soils, especially the richest, good cultivation ranked higher than good manuring. Now, the question under consideration was not, as it would appear at the first glance, confined to the cultivation of one single crop. They all knew that it was to the root crop they looked for that primary cultivation, that foundation of good farming, which was to follow throughout the rotation. The root crop was, in other words, the cultivation crop; and the success or otherwise of the whole rotation depended upon whether the root crop was put in well or ill—whether the work was carried out early, and clean cultivation proceeded with, so that the crop might be put in properly, or whether a contrary course was pursued. Thus it would be seen that it was the question of cultivation, as a whole, that they had to consider. Now, they all very well knew what the old system of preparing for root crops

had been, in times past. Far too generally the stubbles were neglected until the wheat sowing was finished, unless it happened to be very wet; and when the land was not fit for the horses to go upon it, they were sent in to "poach," tread it down, and plough. Then in the month of February it was customary to cross-plough, and work the land as they could in the spring; and they all knew that they could not work when they would, at that season of the year. But after a variety of cross-ploughing, scarifying, and harrowing, the work was carried on somehow or other so as to get the crop in during the month of May, or perhaps not until June or even July. Mr. Pusey, in the Royal Agricultural Society's Journal, gave a description of the old system in much better terms than he could:

"The usual method has been to let the sheep range over the grassy stubbles in autumn, and give the land a winter ploughing towards Christmas. In dry, spring weather it is again ploughed to bring the couch uppermost, drag-harrowed with three or four horses to break the furrows, scarified with four or five horses to bring up the long roots, heavy rolled with three or four to squeeze the clods, light harrowed, light rolled again, light harrowed again, then all the hands turn out with rakes to gather this unravelled network, heap it, and burn it. But if the ground be really foul you have not done yet. After a few days you see fresh blades of grass shooting up over the bare ground, and find the enemy still left behind, so that the ploughing, harrowing, rolling, raking, and burning must begin over again—very likely be repeated a third time."

Mr. Darby observed he did not mean to say that a few years since it was as bad as this in every case; but still on heavy soils it was a very fair description of what the old method used to be. Now, this system had many disadvantages. As he had said before, if the stubbles were ploughed when too wet, they were "poached," and the surface did not present that presence to atmospheric agency which they all liked to have throughout the winter, so that the atmospheric air could get in and disintegrate the particles of the soil. Then again, from the uncertainty of the weather in spring, the after-culture was hurried in a manner it ought not to be, and this was a very great disadvantage in the old method of treating stubbles. From the same cause the crop was often put in very badly, and the land not properly cleaned; then they found couch grass spring up among the turnips, which was never got rid of, and the land got fouler and fouler, until it came to turnips again. The sowing was likewise often thrown backward, and the crop endangered altogether. Another great disadvantage was that the weeds were left in the soil throughout the winter, where they grew, and robbed the land of that ammonia which ought to be stored up for the future crops. It was now an acknowledged axiom that if the land be properly cultivated, it gets throughout the winter from 2 cwt. to 3 cwt. of ammonia from the atmosphere. Then another serious disadvantage of the old method was, that it very often interfered with the sowing of other crops. He now came to the question of expense. It had been proved by all who had tried the two systems that the old way of treating the soil was a very expensive one (Hear, hear). Mr. Pusey, in the article which he had quoted, gave an estimate of the expense of the operations under the old system at £2 9s. 6d. per acre; but although this was stated to be on heavy land, he (Mr. Darby) thought it a rather exaggerated estimate. He thought few of them who had tried the old way of treating stubbles would consider they had ever expended much above £2 per acre. But that was a great expense to incur in the prepararation of land for turnips; and he should suppose that the cost of autumn cleaning would not be above £1 or £1 5s. per acre at the outside. Well, these disadvantages had in many cases led to gradual improvement. Years ago they were felt so much that many excellent farmers wrote on the subject, and endeavoured to prove that stubbles ought to be ploughed as soon after harvest as possible; but still after ploughing they allowed the land to remain all the winter just as it was before, and although it presented a better surface to the atmosphere, yet there were the same objections to be made to the after-culture in spring. He now came to the new system of autumn cultivation for root crops. Most of them knew what it was; but still, in order to make the opening of the subject more complete, he supposed a short description would be necessary. The modern system was to go over the stubbles, where foul, with some cultivator, either Bentall's or Coleman's, as soon after harvest as possible: some farmers who were willing to go "the whole hog" had actually performed this work while the corn was on the land. They had cut the corn, put it in "stetches," raked the hand, and commenced this work of scarifying before the crop was carried. Few of those present, however, commenced quite so early as that; but the argument in favour of the plan was, that while the fine weather lasted they ought to take every fine day they could to perform this work, and it was stated that when cutting corn there were generally some horses thrown out of work which ought to be thus employed. But although it might not be convenient for all of them to do this, the general practice was that it should be done as early as possible in September. Of course the expense of this new system depended upon the foulness of the land, and whether it was of a light or heavy character. Sometimes merely going over it once would be sufficient, following after with the harrows, then raking it up, and burning it. Indeed, some farmers were in the habit of first going with men to fork out the couch where it is not very foul, and afterwards merely giving the land a little surface scratching; it all depended upon the state of the stubbles. But to lay down a rule, of course the new system meant that all the surface should be cleaned, and the land worked as early as possible in the autumn. Mr. John Grey, in a discussion on weeds at the Hexham Club, said:—

"He began, as soon as the crop was stored, or as soon as possible, with skim-ploughing the surface, harrowing and raking it together, and carting it off, putting it into the fold-yard to be the nucleus of the manure heap for next year. He then gave the land a deep ploughing, harrowed it, and put it into drills

ready for the manure: when the manure was put in he reversed the drills, and so it lay, and nearly one-half of his turnip land was now in that condition, drilled, manured, and exposed to all the changes of the atmosphere during the winter. It came to be found in a mellow condition in the spring, and the turnips were sown upon this; whereas, if the land required to be worked up in a damp state, he could not make turnips of it at all: and for the few years he had practised this he had never failed in finding that the turnips sown upon that portion of the land came quickest into leaf, and overcame in the shortest period that great difficulty of rearing a good crop of turnips—that of coming quickly to the hoe. He ascribed it to this reason: the land upon the top of the drill was exceedingly mellow and fine; the manure had been undergoing not the fermentation which it got when thrown into great heaps, where it dispersed its ammonia into the air, and wasted much of its best virtues, but it underwent the slow and quiet process of fermentation throughout the winter, covered up with soil; and they found in the spring all the soil contiguous to the manure in a soft and brown condition, having inhaled much of the virtue which the manure had given off."

It would be perceived that Mr. Grey not only cleaned his land, but actually manured it in the autumn, thus preparing it in every way. After the land had been cleaned, he (Mr. Darby) thought it was advisable, from his own little experience, to allow it to remain two or three weeks, in order that the seeds of annuals, such as charlock, should spring up and vegetate; and then they ought to give the land a very deep ploughing. He was aware that many objected to this deep ploughing, and merely applied the cleaning system after; but he did not think the work was complete on the generality of soils without deep ploughing. As soon as the land was rid of all surface-roots and weeds, and after there had been time for the annuals to spring up, he gave the land a deep ploughing, and then allowed it to remain for the atmosphere to act upon it. Perhaps upon some light soils it was not so desirable to follow the deep ploughing, but even here it did no harm. In fact, the report of experiments in deep ploughing, which obtained a gold medal premium, and appears in the *Farmer's Magazine*, gave reasons to show that deep ploughing even on light land was beneficial; and the writer stated that in an experiment which had been made, the turnip crop showed an excess of 4 tons 13 cwt. 3 qrs. and 21 lbs. where the land had been trench-ploughed, over where it had been shallowed-ploughed. He summed up the whole question with these practical deductions:—

First: That deep ploughing increases the produce of both green and grain crops; and this the reporter states not only from what these experiments point to, but from having grown green crops, after trench-ploughing, on 180 acres, and grain crops on 135 acres of land, with uniform success.

Second: That trench-ploughing tendings to firm or consolidate light land. This is stated from the fact, that on walking across the stubble-field the writer felt the shallow-ploughed land more loose than the trench-ploughed land; and this is also supported by the fact already stated, viz., that the crop on the shallow-ploughed land had a greater lean-over than the other, while the quantity of grain was less; showing that, however forced, it is impossible on weak light land to grow very large crops without deep cultivation, as the mechanical texture of the surface cannot support beyond a certain quantity. Mr. Darby continued to observe that in the aggregate of soils they might say there was nothing like deep cultivation in autumn, if the weather was dry and the surface well cleaned. Now they were in a position to consider the advantages of the new system. All the disadvantages of the old system were done away with by the autumn-cleaning of the stubbles; the soil was exposed to the action of the frosts during winter, the couch and other weeds were removed, and all that came into the soil was reserved there as a store for future crops, and the danger of late cropping was avoided. When the land was thus ploughed up, it merely required the scarifying across it in the month of March to kill the annuals and other weeds that had grown upon the surface, and it would be fit for the crop to be put in. Then the injury done to the land by "poaching" and pulling it about when it was in an unfit state was entirely obviated. Another important point was the fact that the expense was materially lightened when the system was followed up from year to year; the stubbles got so clean that they scarcely wanted any scarifying after harvest at all. Instead of this, many farmers in Norfolk were in the habit of sending out their men, and they could actually fork out the couch grass for 1s. per acre. This showed how clean the stubbles were likely to become when the system was carried out for any length of time. One of the primary advantages of following the autumnal cultivation was, that the land was left in a most favourable state during the winter for the mechanical action of the atmosphere, and when they wanted to go to it in spring they found it in a beautiful "tilth," Nature having done for them what they could not have done half so well themselves. Also, when the land had been cultivated in this way, it took from the atmosphere a great quantity of manure. It was quite a new discovery that the soil did actually take manure from the air; and it was asserted that the quantity of carbonate of ammonia which fell from the atmosphere and entered into the soil was equal to 2 cwt. of guano, when the land was in a fit state to receive it; but when it was not, it did not enter into the soil, or was fed on by the weeds. Some chemists maintained that it did not come from the carbonate of ammonia in the atmosphere, but from the air itself, which had an inexhaustible quantity of nitrogen in its composition, being as much as four-fifths of the whole; and they said that when the crude matters in the soil were turned up, and the air allowed to enter into the interstices, the latter was actually decomposed, the oxygen flying off and the nitrogen being preserved; so that if this be the case, there was no limit to the quantity of ammonia that might be drawn from the atmosphere in the shape of nitrogen, if the proper conditions were carried out. Professor Balfour, in his "Manual of Botany," says—

"Mielder maintains that the ammonia is not carried down from the atmosphere, but is produced in the soil by the combination between the nitrogen of

the air and the hydrogen of decomposing matters. The same thing takes place as in the natural saltpetre caverns of Ceylon, with the exception that by the subsequent action of oxygen, ulmic, humic, geic, apocrenic, and crenic acids are formed, instead of nitric acid. These acids consists of carbon, oxygen, and hydrogen, in different proportions; and they form soluble salts with ammonia. By all porous substances, like the soil, ammonia is produced, provided they be moist and filled with atmospheric air, and are exposed to a certain temperature. It is thus, he states, that moist charcoal and humic become impregnated with ammonia."

Mr. Darby said he had never seen this view very prominently brought before the public. English chemists, in giving reasons why the land did take so very much from the atmosphere, were, he thought, too ready to fall back upon the old theory, that there was a little carbonate of ammonia in the air, which was washed down by the rain. But it appeared to him that the former theory was the correct one. They all knew that the air was filled with manure—at least, with nitrogen; and it had now been proved by the Rev. Mr. Smith, who followed the Lois Weedon system, that land of the character he farmed might be kept in good condition, and grow corn crops without the addition of a particle of manure. During an experience of twelve years Mr. Smith had found his crops progress rather than retrogress. The system had been tried at other places, but had not answered so well as on Mr. Smith's farm; but it was considered to be satisfactorily proved that, if the land was prepared in a certain manner, it would get a large quantity of manure from the ammonia in the atmosphere. Professor Way had paid great attention to the capability of certain soils to attract and retain ammonia, and he had discovered that this varied according to the nature of the soil. In numerous and varied experiments Professor Way has shown that, where a comparatively weak solution of caustic ammonia is passed through a considerable quantity of soil, it invariably loses the ammonia, although previous to filtration it exhibited decidedly the peculiar odour of that volatile alkali. When, however, stronger solutions of ammonia were filtered through soil, or when the proportion of the latter was greatly diminished, only a portion of the ammonia was absorbed, and the remainder passed through the soil with the water. Still more important than the facts respecting the rapid absorption of free alkalies by soils, is the observation made by the same indefatigable philosopher—that all cultivated soils possess likewise the power of separating the ammonia from its combinations with various acids. If, for instance, a solution of sulphate of ammonia of moderate strength is passed through a filter-bed of soil five to eight inches deep, it will be found that the ammonia alone of the sulphate of ammonia is retained, and the sulphuric acid with which the volatile alkali is combined will then be found passing through with the water—generally, though not always, in combination with lime. 1,000 grains of a light red soil from Mr. Pusey's estate absorbed 1,570 grains of ammonia, 1,000 grains from the Dorset Downs absorbed 3,438 grains, 1,000 grains from the white plastic clay absorbed 2,847 grains, 1,000 grains of subsoil clay, red with oxide of iron, absorbed 818 grains. Mr. Darby continued to observe that they found, from Professor Way's experiments, that the capabilities of different soils to absorb ammonia were very different, and this would account for the advantages Mr. Smith derived from the Lois Weedon system, it not having been experienced in other cases. There was yet another advantage arising from autumn cultivation. Many, he supposed all of them, were to a certain extent in the habit of sowing spring feed for sheep, such as rye or early vetches. When this was done, it would be very much better to sow the rye or vetches into barley lands where the stubble had been cleaned than where they were foul. Then, if the land was cleaned in this way, it was not impracticable to have a seed-bed of plants, such as cabbage or kohl-rabi, or even rape plants, to plant out in the early part of September, after the land had been surface-rid in the manner described. He recollected an instance, when he was a boy, in Somersetshire, of a farmer, who was rather more enterprizing than his neighbours, growing rape plants on one side of a field, and as he cut the corn he ploughed the land and put the rape plants in the furrows, and he had a very excellent crop. It had been observed by Mr. Phippard, at their annual meeting, that it was the custom in some places to sow stubble turnips. Now, if they were to sow kohl-rabi, or cabbage, or rape plants, it was not impracticable on a small scale to have a nice bit of feed for the month of May, where they had had a good corn crop cut in August. In fact, when they got in the habit of adopting and carrying out this system, it would create quite a revolution in agriculture, and they might be led to follow the Belgian plan of raising plants in seed-beds, and planting them out after the corn had been harvested. There were many obstacles in the way of its adoption on a larger scale, as autumn cultivation on extensive farms required a great deal of horse-strength, and it was not every one who had the power to carry it out as he could wish. The fine weather was very short, and when they thought they were going to clean and work well, the wet weather might come on, and they could not do half what they intended. This had induced some gentlemen to commence before the corn was carted off the land; and it was worth while considering whether or not it was practicable to do so. But they all knew very well that in harvest time it was very busy work, and if they wished to do it they had to attend to the primary thing first—namely, cutting and harvesting the corn. Probably, however, before many years there would be a remedy for this in the steam plough, which was being brought to such perfection that they might anticipate seeing it in operation upon most of our large farms before long, and then there would be no difficulty in carrying out the system of autumnal cleaning of the stubbles during the fine weather. However, the experience of the Norfolk gentlemen, to whom he had alluded, showed that the main obstacles had only to be encountered at the commencement of the system, and that, after a time, it was far less difficult to do the work (Hear, hear). It had often been said that agriculture, to become perfect, must approximate to garden culture; and what

could tend to raise it to that pitch more than the adoption of the system which, as soon as the corn is removed, rids the land of weeds, and prepares it to be a store-house of the fertilizing principles obtained through the atmospheric agency for the use of succeeding crops? In his opinion nothing was calculated to produce that desideratum, the causing of agriculture to approach to garden culture, more than this system, if deep cultivation be carried out with it. There was another question, which was that of late they had found it quite essential to pay more attention than hitherto to the cultivation of the turnip crops. It was quite certain that turnips were more difficult to grow than had been the case, and some Cassandras amongst them had predicted that the turnip crop would fail in the same manner as the potatoes had. That formed an additional reason why they should pay more attention to their culture, and hasten on the work in the early part of the autumn; for all allowed that when done in dry weather the land really got into a better state, and that there was more chance of a good crop being realized than by the old system (Hear, hear). Then again, owing to the frequent failures in the turnip crops of late, the generality of farmers were turning attention to the mangold crops; and where this was done, it was quite necessary autumn cultivation should be carried out. Mangold required to be put in much earlier than turnips; and on large farms, and small ones also, it was difficult, if not impossible, to cultivate them without pursuing the new system. Therefore the aspect of the times was, as it were, forcing them to adopt autumnal cultivation for root crops. He was satisfied that the more this system was carried out, the more certain would root culture become—they would make more sure of their crops, and get a larger weight per acre; in consequence of that, a larger number of sheep and cattle would be kept on the land; and it would tend to the almost total eradication of couch-grass and other weeds. Thus by fostering clean and good cultivation the system of autumnal cultivation would tend more than anything else to accelerate agricultural progress.

Mr. RANDALL, after complimenting Mr. Darby on the able manner in which he had introduced the subject, said he should like to know whether he considered ploughing-in the stubble was any advantage to the land. The new system that had been recommended was to rake the stubble together and take it off. Now, for his own part he was of opinion that the stubble was of great advantage to mix up with the soil. This year he had been trying a somewhat new system: he had raftered over the stubble, then used a Bentall, and afterwards ploughed it down. He believed it would be rotted in the soil, which would be benefited thereby.

Mr. LONGMAN thought it would do very well where the land was clean.

Mr. SAUNDERS quite agreed with Mr. Darby that autumn cleaning was the foundation of good farming. In the first place it allowed them to have a green crop for sheep in the following spring, whereas otherwise they would have nothing but fallow to work upon at that season of the year. Many of them, however, drove out the autumn cleaning too late; and he thought there should be paid quite as much attention to this as to harvesting. He certainly had never gone "the whole hog" and got between the "stetches," neither had he got so close after them as he ought to have done. He endeavoured to cut and carry his foulest piece first, where he thought it required considerable autumn cleaning, and then go in with oxen directly afterwards. He had got two of Bentall's because the season would scarcely allow him to do sufficient work with one. For autumn cleaning the corn ought to be cut as close as possible, because where there was so much stubble it was more difficult to work and get the couch out. He quite coincided with Mr. Darby that it would not cost half so much to keep a farm clean as to keep it foul. He worked the Bentall as soon after harvest as possible, dressed the land about till the weeds, &c., were dead, and then ploughed it down; and it did not require ploughing, but once afterwards, if the land was in a tolerably clean state. He did not think it advisable to let it stay about till the seeds of the annuals came up, as it was in the fall of the year that they shed their seeds. He had seldom got very little land but what he put to green crop at the fall. He had, however, ten or a dozen acres of fallow last year—which he had not had for many years before; and he found he was out of pocket by that fallow, as the succeeding crop was much less than where he had grown the green crop. While mutton was 7½d. per lb. it paid better than wheat at £10 or £11 a load; therefore he thought they ought to do as much as possible to cultivate the land in autumn, so as to grow spring food for the sheep. Where they had a great quantity of stubble he recommended that they should make a sort of rick of it, observing that he was very glad of it for bedding. He was not for burying any straw, as he could scarcely get enough to bed his animals; and he thought they could make more of it than by burning it into ashes. He also thought that, if the land was ploughed deep, it must be after it was thoroughly cleaned, otherwise they would have the couch under the plough next time; neither did he think they should plough the manure in too deep. In reference to another point, he observed that he did not think a man could look into a piece of land closely enough to take out every bit of couch, for 1s. an acre. It was the small bits that they wanted to take out, so as to destroy the family; and he was in the habit of paying half-a-crown per acre. In conclusion, he made a few remarks on the advisability of not laying down fallows too plain, as they gained more benefit from the atmosphere when rough.

Mr. JACKSON said, where he had had winter oats which he intended to bring to vetches, he had Bentalled between the "hoyles," and cleaned the land, before he had carted the corn. He thought it highly important that they should endeavour to get the plough in the land directly after the crop was off, if not before: he always endeavoured to keep two ploughs going during harvest. There was one advantage attending autumn cultivation Mr. Darby had forgotten to mention, which was

that, when the couch, or whatever it might be, was got out in the fall, it did not leave any food for the grub, wireworm, &c, or at least tended to starve these innocent creatures out. He agreed with Mr. Randall that, if the stubble were ploughed in, it was beneficial to the land, provided it was quite clean; but he thought they would be paying very dear for the use of the stubble, if it was ploughed in full of weeds. Instead of burying it, he usually adopted the system of carting it into heaps, to make useful manure.

Mr. FOWLER thought it was an open question whether the land really did take up so much ammonia from the atmosphere as theoretical men would make them believe. He recollected some years ago there was a sort of paper war between the Rev. Mr. Huxtable and the farmers generally, about growing wheat at 5s. a bushel, and mutton at 4d. a pound. (A voice: "No, no—not 4d.") Mr. Huxtable drew comparisons about the amount of ammonia that was required to be used in the land to produce a certain quantity of wheat; and he also said the land naturally produced a certain quantity of wheat itself, without the use of that ammonia. Liebig, to contravert that, in his work on Agricultural Chemistry, said it was quite useless to apply ammonia to the land, because the air itself would supply it, without artificial application; and he illustrated it by asking how forests and woods were produced without the use of ammonia? Now, he did not mean to say Liebig was wrong in all his theoretical views; but he appeared to have forgotten that the air supplied ammonia to the shrubs and trees by its being taken up by the leaves; and these leaves, falling in autumn, supplied ammonia to the land. He thought it was a question whether theoretical men were not at fault in stating that the air supplied a certain quantity of ammonia to the land, or whether, by deep cultivation, the air did not rid the soil of certain putrid fluids, and render it in a better state to take up the manures which were applied to it.

Mr. R. DAMEN was of opinion that, generally speaking, there was no surplus labour to carry out the autumn system as it should be; but if they would make a little sacrifice, by putting on a few oxen and men for the purpose, it would pay very well, because, as had been said before, when once the work was begun, in the course of three or four years it would be much less; but it would be necessary to make some sacrifice at the time of harvest. Now, although they could not go on so fast as Mr. Jackson, and get between the "stetches," he felt sure much might be done even in small ways to begin with. The oxen on a farm were not useful in carting corn, and in some cases were not employed at all during harvest; and if they could be kept on ploughing and scarifying, and doing what was necessary, with a few hands, he believed it would be very valuable to the farmer, and conducive to the most beneficial results.

Mr. CLARKE could not fall in with the views expressed respecting their getting in between the "stetches," because at that time of the year they had enough to do to remove them once, instead of twice; but as soon as they were removed, he thought it very essential to apply Bentall's scarifier, the stubbles being cut close. He obtained one last year; but, unfortunately, it came rather too late. Still, he had the advantage of one week of fine weather; and he was only sorry he had not had it three weeks earlier. If he had, he could have made the land as clean as any garden-ground. He put the scarifier right across the ridges, and moved every bit of it. The drags were put in behind; and then, after that, he went over it with a light roller, harrowed it, and got it in such a state that, if he had thought proper, he could have ploughed every bit of it in, without raking it into heaps and burning it. They had all got their own favourite plan; but he liked burning, because he did not relish seeing so much of this couch about. Few could say they had not any couch on their farm; and where the land was not properly drained, he hardly thought it possible to avoid having some. With respect to employing oxen during the harvest, he always found it difficult enough to get men to perform the harvest-work.

Mr. JACKSON hoped they would not think he intended to advocate going between the stetches right through the harvest. Where he had done so was, where he had cut winter oats or rye, and when not in the thick of the harvest.

The CHAIRMAN proposed a vote of thanks to Mr. Darby for the able manner in which he had brought forward the subject.

Mr. SAUNDERS briefly seconded the proposition; and it was carried with acclamation.

Mr. DARBY, in returning thanks, expressed the gratification afforded him to find his observations had been received so favourably; for, although he was convinced there were not two opinions in the minds of good farmers as to the benefit of autumn cultivation, yet the subject embraced a vast variety of matters in which there must be difference of opinion. Some had light land, while others had heavy land, which would cause a difference in carrying out the details. Some land required to be "raftered" before the scarifier was put across it; but in light land it was quite as well to use the implement before being "raftered." He quite agreed with Mr. Randall that, where there was no twitch-grass, no couch, it was quite as well to proceed to deep ploughing, or to the ploughing they wanted, as to use a scarifier. The use of that implement was to clean the land; and if it were clean already, they could dispense with it. When the land was comparatively clean, men with forks would do the work; and Mr. Acland, in his Essay on the Farming of Somersetshire, stated that Mr. Hudson, of Castleacre, paid 1s. per acre for having the work done; but on the generality of farms, he (Mr. Darby) thought 2s. 6d. was the average price. He was much obliged to Mr. Jackson for having called his attention to one advantage of autumn cleaning—the removal of food for the grub and wireworm during the winter, which he had omitted to comment upon. With regard to Mr. Fowler's objection to the ammonia theory, according to which the land took nitrogen from the air, and converted it into ammonia, they must recollect that this was not all theory—that actually theory came after practice. It was a fact that our scientific men were not aware that such was the case,

until the experiments of Mr. Smith, on the Lois-Weedon system, drew their attention to the circumstance. It was a generally-received fact that the soil did take up ammonia from the air; and the only difference of opinion was as to the quantity. He was sorry that Mr. Fowler had left the room before he made these remarks. With respect to burning the stubble and couch, or taking it away, he did not dogmatize on that point; for he was aware that some were in the habit of burning it, while others made use of it in different ways; and during the last autumn, he himself had taken it into the yard, leaving it as a bed for the manure, and also mixing it up with dung, in heaps, to decay. After again returning thanks for the eulogiums that had been passed upon him, Mr. Darby submitted the following resolution:

"That the more general adoption of autumn culture for the root-crop is highly desirable; that, in comparatively clean stubble, the couch grass may be forked out with manual labour, and in all other cases the land should be scarified or surface-worked as soon after harvest as possible, and the whole of the refuse either raked off for future use, burnt, or, if wholly killed, allowed to remain, as might be deemed desirable; and that afterwards, where the land is not sown to a green crop for feeding off in the succeeding spring, it should in the generality of cases be deeply ploughed, and remain in that state during the winter."

This resolution having been carried without a dissentient, the formal proceedings of the evening were brought to a close.

DISTILLATION FROM BEET ROOTS AT THE RUDDINGTON DISTILLERY.

For some time past the subject of distillation of neutral spirit from beet roots has occupied the attention of many of our most eminent agriculturists. The invention of the system is of French origin, and the practice has been and continues to be successfully carried on across the channel. At first its introduction into this country was strongly opposed by existing interests, and prejudice continues strong against it, especially in the minds of those who enjoy a lucrative monopoly. But a spirit of progress animates many of our leading agriculturists, which is not to be resisted, and, after the most urgent representations, the Government were induced to relax their prohibitive policy so far as to permit twelve stills to be established in the United Kingdom. Among those who have taken a most lively interest in the matter, Sir T. Parkyns, of Ruddington, near Nottingham, is fairly entitled to rank among the foremost. One of the first to avail himself of the permissive indulgence of the Government, he entered into an arrangement with Messrs. W. Dray and Co. for a complete apparatus for the object he had in view, and being determined to spare no pains or expense to ensure the complete success of the undertaking, he engaged the services of M. Crolard, an eminent French distiller by the new system. This distillery has now been in operation about a month, and a few days ago we had the pleasure of inspecting the premises and witnessing the process, the details of which the respected and spirited proprietor explained.

The distillery occupies a favourable position on the farm on the outskirts of the pleasantly situated village of Ruddington, and the buildings have a very neat and compact appearance. They consist of a rectangular block, comprising the distillery proper, and the Receiving and Bonded Warehouses, the latter being kept under Government lock-and-key by an officer of excise, who has an office adjoining. The distillery is about 80 feet in length by 40 feet in width, and has a spacious and lofty appearance. Here we have the machinery for the entire process, from the washing of the roots to the production of the spirit; and our object is now briefly to describe its appearance. On entering the distillery by a pair of large sliding doors at the east end of the building, the first object which attracts attention is an upright steam engine of six-horse power, with a cylindrical boiler of most compact appearance. To the right of the engine are placed the washing and cutting machines, both of which are propelled by steam. The former of these has the appearance of a large wooden trough, stands about five feet high, and is some nine feet in length by 2 ft. 6 in. or 3 feet in breadth. In this trough or cistern is placed a revolving washing or brushing apparatus, which effectually cleanses all dirt from the roots as they pass through from one end, into which they are thrown by a boy, to the other, from which they are delivered by the action of the machine. The roots vary in size, probably from 3 or 4 to 6 or 7 pounds each, and if kept constantly at work the machine will wash about twenty tons per day. The cutting machine is of small size, and equally simple in construction with that for washing, and it is also worked by steam power. As the roots come from the washer they are thrown into the cutter by a boy, and from there are reduced into thin slices. The cutting machine is calculated to keep pace, as regards quantity of work, with the washer. In following the order of the process of distillation, the next objects of interest are the fermenting vats. These are twelve in number, each capable of holding 200 gallons, and they are arranged round the opposite end of the building. On the first preparation of these vats they are filled about two-thirds full of water, which is heated by steam to some 120 degrees. A quantity of sulphuric acid is added, and the heat is then allowed to subside to about 84 degrees, when the sliced roots are put in to undergo the process of fermentation which is induced by yeast. While that is going on the "still-proper" attracts one's attention. To a person perfectly unacquainted with such matters this seems to be an exceedingly complex affair, and the process of distillation is certainly most delicate

and difficult. In the first place there are five iron cylinders, each being connected with the steam boiler by a pipe for the purpose of obtaining a supply of steam, and again by means of another pipe a passage is formed by which the spirit passes into the rectifying boiler, a circular iron construction which stands about six feet high, and is probably from four to five feet in diameter. It is divided into two equal compartments, connected by means of brass pipes with stop taps. From the top of this boiler rises a formidable looking column, known as the rectifier, through which three brass pipes pass backwards and forwards from side to side, rising gradually to the top. From the upper plates of the apparatus the spirit is obtained at from 60 to 70 degrees over proof—the best running off at about the thirteenth plate from the top. The discharge is made through a glass case, which is kept locked by the excise officer, and from hence the spirit passes into the receiver.

But to return to the process. We left the sliced roots undergoing fermentation in the capacious vats. When they have been sufficiently acted upon by the acid, they are taken out by means of nets fixed on the ends of long poles, and placed in one or other of the iron cylinders before alluded to. Here they are exposed to the action of steam, which drives the spirit in vapour through the connecting pipes into the upper compartment of the boiler, in which it is condensed. It is then allowed to pass into the lower compartment, in which, by means of steam, it is again converted into vapour and rises up through the plates in the column resting on the top of the boiler, and being condensed in a worm tube it is delivered at the safe as above described. The water left in the lower part of the adjoining cylinder is then drawn off, the refuse roots removed, and the process repeated. Altogether the number of men and boys employed in the distillery is 28—14 in the day and a like number during the night, as it is absolutely necessary to keep the work constantly going on. M. Leplay, a Frenchman, is the inventor of the system.

Having described the process we now come to look at the undertaking in a commercial and agricultural point of view. The establishment of such a concern in a small place like Ruddington is an event of the greatest importance, notwithstanding the number of hands employed being, comparatively speaking, small. The erection of the premises has been going on during the late season of depressed trade, and many of the poor stocking weavers of the village have found temporary employment in connection therewith as labourers, which has enabled them to avert the hard alternative of applying for parochial aid. The constant employment of some twenty-eight hands will also add materially to the resources of the villagers. We say constant employment, because, though the process of distillation will only be carried on during the winter months, the hands will in summer take the place on the farm of the extraneous labourers which at that season every farmer has always to employ. The effect will be to increase the settled and permanent population of the parish, and ensure to that increase a continuance of the labour necessary for earning a comfortable sustenance.

As a commercial speculation we think the spirited proprietor of the undertaking has every reason to be sanguine of the most complete success crowning his efforts. The spirit produced is, as a general rule, from 60 to 70 degrees over proof, and is considered by our townsman, Mr. Parr, chymist, to be equal to any description already in use for all pharmaceutical and chemical purposes. We understand that Mr. Parr is now engaged in conducting a series of experiments with the spirit, the result of which will be made known as soon as completed. The cheapness at which the spirit can be produced will operate as an inducement to consumers to use it as extensively as possible, and there can be little doubt that so soon as the merits of the spirit become generally known there will be a universal and continually increasing demand. At present, we are informed that the production of spirit at this distillery is at the rate of some 12 or 14 gallons from a ton of roots, and M. Crolard, the manager, speaking from experience, says that when the works are thoroughly completed and in good working-order he will be able to produce 20 gallons per ton. Calculating the expenditure on a liberal scale, and estimating the roots to cost 18s. per ton, the sale of the spirit at 2s. to 2s. 6d. per gallon, proof, according to quality, will not only cover cost of production, but leave a small margin of profit, even supposing the residue of the roots to be of no value, which, however, is far from being the case, as we shall have occasion to show. The quantity of roots used will average from 15 to 18 tons per day, and the season for distillation extending over about seven months in the year, the quantity used annually will exceed 3,000 tons, so that the distillery will form a very important addition to the demand for the agricultural produce of the district. The quantity of spirit produced from the above quantity of roots will not be less, at a moderate computation, than 50,000 gallons.

But in calculating the prospective profits or losses of such an undertaking, we must not overlook the residue of the roots after the sugar has been extracted and converted into spirit. For the fattening of cattle this residue is held by some parties to be as valuable as the roots themselves. So far as experience goes it would appear to support even this extreme view; but at any rate the value at present put upon this residue is some 12s. per ton. When used along with barley flour, from hinder ends, worth about 25s. per quarter, or bean flour and cut chaff, the cattle feed upon it with amazing rapidity. The quantity of barley flour given is about 7 lbs. per day, valued at 3½d. On Wednesday, the 24th ult., three fine beasts fed in this way were exhibited in the Nottingham market, where they attracted much attention, and were quickly bought up at good prices. We are assured that cattle fed with this residue are ready for the market in nearly one-third less time than those treated in the usual way, which in itself is a very important consideration to a farmer. At present Sir Thomas Parkyns has nearly 100 head of cattle being fed on the residue of distilled roots, so that in a short time their precise value will be placed beyond a doubt. One peculiar property of this residue ought not to be overlooked. While the

roots themselves lose their nutritive properties by being kept over the season, however carefully cared for, the residue may be kept for two or three years without losing any of its value. This prevents any loss being sustained by an agricultural distiller from fluctuations in the demand for the residue. In case demand should at any time fail to keep pace with the supply, the residue has only to be stored in pits, when a crust forms on the outside, and the whole mass becomes, as it were, hermetically sealed. In this state it will keep a long time without sustaining any sensible decrease of nutritive value.

We think sufficient has now been said to excite an interest in the minds of our agricultural readers in the success of so spirited an undertaking, but on some future occasion we may revert to the results which have attended the cultivation and distillation of beet roots in France.—Nottingham Guardian.

THE QUALITIES CONSTITUTING A GOOD POTATO.

Many varieties of potatoes, like new seedling grapes, are being constantly brought before the public. No sooner does one variety get advertised and sold, than another, stated to possess far superior qualities, pops into the market. All seem anxious alike for these fine new varieties, even at the expense of discarding some well-known old favourite. Just so with the potato: fresh-named, if not new varieties, are advertised weekly. We have no knowledge where they came from, or who was the fortunate raiser of these said varieties; in fact, we have no guarantee at all as to whether they are really genuine; and, should we be so unfortunate as to buy the same variety of potato under two or three different names, to whom are we to apply for redress? Of course we could not apply to the salesman, for he would tell us that he bought them for so-and-so; but who the right raisers of these varieties are, it would puzzle a conjuror to find out.

I must admit that it is not the case with new varieties of grapes; for we generally have the whole history given, with the raiser's name and address, from what variety raised, where and when exhibited, with its good qualities, &c.

This is precisely what we wish those who advertised new or fresh varieties of potatoes to do. Such a method would show good faith, and protect us from buying so many duplicates. At present it frequently happens when a person has a favourite variety of potato, and does not know its name, that he christens it himself, and gives it away to his friends with this new name attached to it. Again, if he should tell his friends that he does not know the name, it is more than likely that they will call it by the giver's name, such as "Mr. So-and-So's Kidney."

A miller in this part of the country had some fine kidney potatoes, of which he did not know the name: and when he distributed them they were christened Miller's Kidney; and this variety is a great favourite round our neighbourhood, but is no other than the old Midsummer Kidney. So, the Champion Kidney is identical with the Albion; yet both have different raisers' names.

There are, also, many varieties now in cultivation that are known only by their names; their origin was never made public. Many new varieties that have found their way into the market are entirely worthless; and many old varieties of really good value have either been discarded for new ones, or have been entirely lost through bad management or neglect. It is a well-known fact that some varieties that are of first-rate quality when grown in some parts of the country, are entirely worthless when grown in other parts, and to this fact we should all pay great attention. For instance, how very different are some of the potatoes grown in Lancashire to what they are in this neighbourhood! In the former they boil like a ball of flour, in the latter they are like a ball of wax; but I think it must be admitted that more potatoes are condemned through bad cooking than from any other cause. The more waxy the potato, the more salt will be required for the water to boil them in.

In raising new varieties the following points are indispensable, and none but those that have such merits described below should be submitted for sale to the public; for it is far more important to the public at large to have a first-class potato than a first-class grape offered to them. Potatoes are food for millions, while the grape is only a luxury for the rich.

A good potato should be in size moderate; shape regular—that is, free from deep eyes, warts, and crooks; skin roughish; when boiled, entireness, dryness, and firmness; agreeable taste, earliness, productiveness, short haulm, freedom from disease, and long keeping.

A large potato is frequently hollow, and cannot be conveniently cooked, and is also liable to be badly boiled. A warty or deep-eyed one suffers waste in peeling; a smooth-skinned one is generally more waxy than a rough one; a bursting one, in boiling water, suffers loss; a firm and dry one is mealy; an early ripening one is less liable to be attacked by disease; and productiveness is requisite to make the crops profitable. Short-haulmed varieties can be planted closer together than long-haulmed; freedom from disease is the great point we wish to acquire, and can certainly only be attained by peculiar methods of cultivation; lastly, a good keeping variety that retains its flavour is indispensable, for the sake of affording its supplies up to the period of Midsummer.

The history of those varieties which are generally favourites now in cultivation would, I am sure, be highly appreciated by your readers; and I trust that your correspondents that are in possession of the history of any well-known variety will kindly communicate it through these valuable columns. Let us reason together, and see if we cannot come to some good understanding on this one neglected point. I promise to lend all the aid in my power, having grown over one hundred so-called varieties within the last four years.—Edward Bennett, Gardener to Sir O. P. Wakeman, Bart., Perdiswell Hall, Worcester, in "Cottage Gardener."

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE REARING AND DISEASES OF LAMBS.

The usual monthly meeting of the Club took place on Monday evening, May 3, at the Club House, Blackfriars.

The subject for discussion, assigned for introduction to Mr. J. Marshall, of Rischolme, Lincolnshire, was thus stated on the card:—"The breeding, rearing, and management of lambs, as a successful means of providing against pleuro-pneumonia and consumption."

The chair was taken by Mr. Owen, of Clapton; and among the other gentlemen present were — Messrs. Owen Wallis, J. Tyler, H. Trethewy, J. A. Williams, E. Little, C. T. James, J. B. Spearing, J. T. Davy, J. Paull, — Paull, junr., Shaw, J. H. Pocock, J. Russell, L. A. Coussmaker, F. Dyball, R. Cobb, J. Cressingham, E. Purser, R. Marsh, C. J. Brickwell, G. S. Harrison, T. Fordham, E. H. Bentall, J. G. King, J. Odams, R. B. Hammond, S. Skelton, Owen, junr., C. Howard, F. Withes.

The CHAIRMAN in introducing the subject characterized the sheep as the best friend the farmer has. He also spoke to the ability and experience of Mr. Marshall as especially qualifying him to introduce such a question to the members of the Club.

Mr. MARSHALL said: Mr. Chairman and Gentlemen, having been requested by the committee at the annual meeting of this Club to propose a subject for discussion at one of our monthly gatherings, I ventured to do so in the earnest expectation that some member whose experience and opinion as a flock-master might have entitled him to greater consideration would have undertaken the task of explaining the cause, or, perhaps, rather of suggesting a successful means of guarding against pleuro-pneumonia and consumption in the breeding, rearing, and management of lambs. I am inclined to approach this most vexatious subject with the greatest diffidence from a knowledge of the many difficulties by which it is at all times unavoidably surrounded. I know of nothing more perplexing, or more productive of anxiety in the mind of a Lincolnshire sheep-breeder, than the ordinary management of his flock, upon a light turnip land farm, during the months of July, August, and September, where it is all arable, or where he has only a small portion of poor weak grass land intermixed; his reliance for its support being placed entirely on the prospect of a good or bad crop of seeds, as a part and parcel of his usual four-field course of husbandry. I will suppose a farm of 500 acres, containing one-fifth of inferior old grass land, and four-fifths of arable dry turnip land, upon which a flock of 400 ewes would, I presume, be kept. One hundred acres of this would, according to the ordinary four-field system, be sown down with seeds, 80 acres for feeding, with 20 lbs. per acre of white clover, trefoil, ribgrass, and parsley seeds; and a very small portion (say about a peck per acre) of any kind of common or dwarf ryegrass, in short with any kind of ryegrass rather than Italian—a plant I have been compelled, from sheer necessity, to discontinue growing to any extent, from the fearful destruction it year by year occasions to the succeeding crop of wheat: it is, in fact, on the thin dry soils of Lincolnshire, positive destruction to it; therefore as a grass for the purposes of alternate husbandry it has been, and I think deservedly so, well nigh altogether exploded; and unless the lands intended for autumn sowing can be ploughed some weeks before putting in the wheat, which should not be deferred beyond the middle of October, no security for a crop after Italian ryegrass can be reasonably calculated upon. The remaining 20 acres will be sown down with 20 lbs. per acre of red clover or cow-grass, for mowing and making into hay for the cart horses, and subsequent eddish for the lambs after they are weaned. Out of a flock of 400 ewes, it mostly happens that from loss in lambing, and from other causes incidental to a breeding flock, not more than 350 to 360 return to their pastures with lambs by their sides; and if 100 of these are fortunate enough to rear two lambs each, it is as many as may be reasonably looked for. There will then be 250 single lambs and 100 pairs to be provided for upon 80 acres of feeding seeds, and 100 acres of old grass land of indifferent quality; 35 acres of the best planted seeds will be stocked with the 100 pairs at the rate of about three ewes and six lambs, or in all nine ewes and lambs per acre. These are allowed half-a-pound to a pound of the best feeding rapecake, or a mixture of two-thirds rape and one-third linseed cake per ewe; or if preference be given to corn, either a pint of oats, barley, peas, or beans, with a small addition of cut hay, clover, or malt-culm, as circumstances and the growth of the pasture may suggest. The remaining 45 acres of seeds will, if tolerably well planted, carry four ewes and single lambs per acre, with or without the foregoing addition of cake or corn, as seasons and the abundance or otherwise of keeping may seem to demand. The remaining 70 ewes and lambs will be grazed on 35 acres (at the rate of 2 per acre) of the old grass land; 50 acres of which will also carry (at the rate of 3 per acre) 150 of the best she-hoggetts, kept back for the purpose of restoring the breeding flock to its original number at Michaelmas. The remaining 15 acres are put into meadow for hay. The whole of the flock are regularly supplied with water, and if they have no pond or running stream to avail themselves of, they must be provided with water-troughs set about the fields for that purpose, and these should never on any account be permitted to be quite empty. I believe, in hot weather, sheep well supplied with water require a great deal less food, and are more comfortable and healthy, than in those localities where this desirable luxury is beyond their reach.

The summer-fed seeds in each of the preceding cases will always be eaten down extremely close; indeed, in a dry summer, it would to a casual observer appear as if they had little or nothing to live upon; yet this apparent scarcity may be relieved by means of the addition of the artificial food to which I have before alluded, and which I think may be always profitably employed in all cases of heavy stocking. In speaking of rapecake, I allude to cake made from rapeseed only; and I have generally found that an addition of linseedcake—say an equal portion of each—might be profitably used after the 1st of July, as about that time the lambs begin to eat a little, and it is very important to get them to do so at the earliest possible period, in order to prepare them for weaning, which generally takes place between the 20th and 30th of the same month. It is at this time that the difficulty commences against which we have so continually to contend. I will suppose the weaning to be concluded by the 25th of July, by, as far as it can be done, removing the ewes from the lambs for a few days, until the latter become fairly settled, and return to their troughs. They are then to be taken from the summer-fed seeds, and regularly laid out over the whole of the 100 acres of old grass land and clover eddish, which will be by this time ready to receive them, in something like the following proportions:—150 of the weakest and worst lambs upon the clover eddish, and the 300 upon the old pasture, the whole receiving ½lb. of linseedcake per day, with a few oats, bran, and malt-culm; or, in short, with any dry artificial food they may incline to eat best, in addition to a few cabbages, four or five acres of which should invariably be grown for this especial purpose. The early York variety, sown in seed-beds in August, and transplanted early in October on well-manured ridges, will be quite ready for eating by the 1st of August, and is by far the best green food given them on grass land, till the 10th of September. They may then be turned upon the early turnips, which, by good management, they soon learn to eat; after which, in the ordinary course of events, no further difficulty or danger is to be apprehended. There are cases, however, in which good management and the greatest assiduity and attention seem to be altogether of little or no avail. I have seen large flocks of lambs, apparently healthy and full of vigour when taken from the ewes, in three to six weeks afterwards the most miserable-looking animals imaginable; and in a month later, perhaps, one-fourth of them dead, or reduced to a state of wretchedness which no nursing, however careful, can ever overcome. The malady to which I am now about to allude, and which for the sake of distinction I will call consumption (leaving pleuro-pneumonia, which is altogether another and a separate disease, entirely out of the question), is a most insidious, and so far it has appeared to be an incurable disorder. In what manner or at what precise period it is engendered, is at present a matter involved in mystery. So long as the lambs are dependent upon the ewes for their support, they appear to go on well enough, and look healthy and flourishing; but as soon as they are deprived of that support, and the keeping upon which they are put does not quite agree with them, they are attacked with this formidable disease, and die by hundreds. Mr. Jekyll, of Lincoln, a person of great eminence as a veterinary surgeon, and in extensive practice, has favoured me with the following remarks upon this subject:—"The earliest symptom which I have observed has been diarrhœa for one, two, or three days, very soon after which a cough commences, and in a short time becomes very troublesome. The lamb partially loses its appetite; a large quantity of green frothy mucous is constantly discharged from the nose; the cough begins to be very distressing; low and debilitating fever sets in, with a complete loss of appetite, great debility and emaciation, under which, and the irritation of the now all but constant cough, the lamb sinks and dies. On making a *post mortem* examination, the first thing which attracted my attention was the very pale and wasted condition of the muscular structures, while a considerable amount of fat remained; the stomach and intestines were pale, and contained very little food, with water, mucus, and fœtid gases; the liver was discoloured, and a little softer than natural; the heart was pale, but otherwise quite healthy; the lungs about their natural size, but marked with singular patches on their surface, while some parts of them appeared natural and healthy. On cutting into the lungs while yet warm, a great number of filaria, small thread-like worms, struggled out of the bronchial tubes, mostly from those parts of the lungs which were inflamed. When I opened the larger bronchial tubes and the trachea, I found a great number of these intruders moving about with as much rapidity and ease as the size of their strange prison-house would allow: their ceaseless vermicular motions appeared exactly calculated to produce great irritation, fever, incessant cough and continuous discharge. As a cure I have tried the internal exhibition of small doses of turpentine with cold gruel, but without success. I have also made them inhale chlorine gas; and the few on which I experimented recovered, but it was late in the season, and I think it likely they would have recovered without this. I intend, however, to make a further trial of this remedy; but while a ready means of cure is of importance to us, the cause and a preventive are of much greater. The history and stages through which these pests pass, and how they enter animal bodies, would very much aid us; but I fear all this is wrapt in a shroud of mystery so deep that science must labour long and perseveringly before she can bring forth the naked facts for the benefit of man. I have observed this affection in all sorts of seasons and on every variety of land, and under every system of management in this large sheep-breeding district." In closing my remarks on this occasion I must be permitted to observe, that however inconclusive and necessarily imperfect in many respects the paper I have had the pleasure to read to you may be considered, its distribution into those districts where the subject of this evening's discussion may be better and more extensively understood, may lead to an investigation of the circumstances and causes of this most mysterious disease, and prove eventually the means of discovering preventive remedies, if not of curative appliances for it.

Much may be done by carefully watching its rise and progress during the summer months. Whether the animalculæ supposed to produce the evil be really viviparous or oviparous is a question which can only be cleared up and settled by experiments hereafter, to be conducted by persons skilled in that department of science, and especially by those possessing a comprehensive knowledge of entomology. Gentlemen, I beg most sincerely to thank you for the kind and patient attention with which you have done me the favour to listen to my long and tedious, though, I hope, not altogether uninteresting address. My own research has hitherto, I am bound to confess, proved unsuccessful. May that of others succeed better. May their labours receive a brighter reward, and their inquiries be unobstructed by any of those impediments over which we have no control, and that have so far baffled the combined efforts of modern investigation.

Mr. J. W. PAULL (Ilminster, Somersetshire) said, as a flockmaster, he felt deeply interested in this subject, having suffered very considerably from the malady referred to by Mr. Marshall, on his farm in the West of England. Mr. Marshall had told them that he finished weaning his ewes as late as July. In the West of England they got the greater part of their lambs not later than January, and they were all off the dams by April. They were, therefore, obliged to have recourse, to a considerable extent, to artificial means of feeding; they were obliged to put their lambs on the best food they could command, for the purpose of supporting them during the cold backward springs. He had, as he had already intimated, been most unfortunate as regarded his lambs. They were seized with a cough, accompanied with a great discharge from the mouth; and when they were dissected the pipes of the lungs were found to be full of small worms. How the worms got there he had never been able to find out. The only means of providing against the evil, that he had discovered, was not to allow the lambs to go upon old pastures. In a backward spring they were obliged to resort to young grasses and tares. His own county appeared to be much more forward than Lincolnshire. The only preventive to the disease, which he had been able to find out, was to change them on pastures which had been fed by beasts the previous year. (Hear, hear). That had sometimes produced a considerable effect. Still he had been a great sufferer from this malady, and he had come to London almost on purpose to hear whether Mr. Marshall could suggest any effectual remedy.

Capt. DAVY (South Molton) had suffered very much from the malady in question, which in his part of the country was called the scour. He had lost an immense per-centage of his lambs. They were dropped chiefly in January and February, and weaned before the end of May. By the end of June numbers of them were taken with a scouring, and a discharge from the nose, and they were soon dead. The best preventive was to remove the lambs to what was termed in Devonshire the after-grass, that was, the grass which came after mowing. He believed one of the causes of this disease was that many persons breed their animals of too delicate constitutions, with too small necks and legs of muttons. If our sheep were of more hardy constitutions they would not suffer so much. As long as lambs lived on their mother's milk (nature's best food, and most easily assimilated by young animals) they did very well; but when they had to shift for themselves, their delicate systems were unable to digest their food and absorb its ingredients. A disordered stomach was the first result; disease followed, and ultimately death.

Mr. PAULL agreed with Captain Davy that it was the after-grass, as well as the change of feeding, that they must look to for relief.

Mr. O. WALLIS (Overstone Grange, Northamptonshire), said in this case they ought to be careful lest they should confound cause and effect. He believed that the worms which had been spoken of as generated in the lambs were the result of previous feeding (Hear, hear). The case resembled that of the discovery of flukes in the livers of rotten sheep. He was inclined to attribute the evil in a great degree to the over-stocking which seemed to prevail in certain districts. The result of this was that the sheep had to search so near the soil for their food that they took up something that was pernicious to the system; disease was generated, a parasite was formed, and that parasite was probably the worm which had been described by Mr. Marshall in his able paper. When he first commenced farming he had only an arable farm; and having no means of changing the food of his stock, he used to lose a very large proportion. It was not at all uncommon for him then to lose a hundred sheep a year on a farm of 400 acres. Under these circumstances he felt that he must either relinquish the breeding of sheep or get some grazing land. He adopted the latter plan. In feeding his sheep he changed from seeds to pasture, and back again from pasture to seeds; and the consequence was that where he formerly lost a hundred sheep he now lost about ten. He considered it essential that there should be a change of pastures, especially with regard to sheep. He also held it to be very important not to let sheep graze very closely. Moreover, sheep should be fed with young bullocks or neat-stock: they got on much better together than separately (Hear, hear). He was also of opinion that if two years' seeds were adopted instead of the four-course system, farmers would be enabled to keep a larger amount of stock, and grow a greater quantity of corn at a less proportionate cost than was incurred at present. Where there was not a sufficient mixture of pasture and arable land, if there were two years' seeds to fall back upon, the malady which appeared to be so prevalent would perhaps, to a great extent, be avoided. At all events, he believed the chief preventive was change, whatever the change might be.

Mr. LITTLE (Landhill, Chippenham) would say a few words with regard to the management of lambs by the flockmasters of Wiltshire. He agreed with Mr. Wallis and Mr. Paull, that change of food was what must be chiefly relied upon as a preventive of disease among sheep. On the sheep-breeding farms of Wiltshire there was no rich pasturage to be found. There they knew nothing of the disease which had been described by Mr.

Marshall, and he was inclined to the opinion that that disease was in a great measure generated by the rich pastures of Lincolnshire. In his county the lambs usually fell in the month of February and March, and after remaining in a sheltered fold till strong enough to stand the weather, they returned to the field to the Swedes or turnips; and after weaning, which took place generally in May or June, the great point with the Wiltshire farmer is to have ready as many changes of food as possible for their lambs; and some farmers in the county (those who produced the best lambs) gave them four or five changes in the day. On the Wiltshire hill farms a large quantity of sainfoin was sown, and he believed that was the best preventive for what was termed "scour" or diarrhœa. Whenever they had disease among their lambs, they naturally turned to sainfoin as the best remedy. He did not know that he could add anything further that would throw any light upon the subject. He knew nothing of the malady in question, but, in his opinion, the best remedy would be found in a change of food, and in the use of sainfoin, where it could be grown.

Mr. WILLIAMS (Baydon, Hungerford) said this subject was one of the greatest importance to farmers generally. When cattle or horses were attacked with disease, the evil might generally be met by having recourse to the veterinary surgeon; but sheep appeared to be beyond the aid of the veterinary surgeon and of science, and previous speakers had alluded to the immense loss which they had themselves sustained, apparently without the power of helping themselves, in their flocks. Coming from the same county as Mr. Little, he could corroborate what had fallen from him, in reference to the absence of the disease in question in that part of the country. In fact, they knew nothing of it from their own experience; it was a malady which was, happily, quite foreign to them. At the same time they were subject to another disease, of a most awful character—a disease which was almost as ruinous as that which had been described by a gentleman from the North. He happened to have travelled to London that day with their Chairman and with Mr. King, and the latter gentleman told him, if he remembered rightly, that he had lost forty lambs within a week; and another gentleman named Pike, who was also present, said he had lost fifty in the same space of time.

Mr. KING—Within a fortnight.

Mr. WILLIAMS—Well, this difference was not very material. Now the disease from which their losses occurred was, as he had already intimated, quite distinct from that described by Mr. Marshall. It differed from the disease in Lincolnshire in this respect, that it depended on the ewe. Hence they had a remedy; but then the remedy was, in this, as in many other cases, worse than the disease. The remedy was to wean the lambs; but the effect of this was that, while they saved the lamb from the scour they injured it in other respects. The question for discussion as stated on the card referred to pleuro-pneumonia and consumption. Now in the case of the disease in his district there were no symptoms observable over night, and they sometimes found three or four of their lambs dead in the morning. If that was consumption, it was certainly very rapid consumption. He had often known a full-grown sheep to go off in the same way. When the shepherd left the fold at night, there was apparently nothing at all wrong: when he went in the morning the sheep was dead. It was a curious fact that in these cases death appeared generally to take place about four o'clock in the morning; and how the disease was to be accounted for he could not pretend to say, but it was most important that something should be done, if possible, to discover a remedy. Their Chairman had told him that he had lost as many as seventy fat lambs within a week. There were three partial remedies to which he would for a moment allude. The first was that to which he had already referred, namely, the early weaning of the lamb, which of course generally had the effect of spoiling it. He had himself resorted to this remedy; and after losing ten lambs a night, he had stopped that species of loss by weaning the remaining lambs at once. Another remedy was to counteract the disease in the ewe by feeding the lambs on something that would act as an antidote; and he found one of the best things was to let the lambs feed on a crop of wheat. As in all probability a great deal of this year's wheat would be lost through excessive luxuriance, and as wheat now fetched so low a price in the market, this remedy appeared to him deserving of special attention. Mr. Little had spoken of the great advantage of feeding on sainfoin. Now that was almost a specific against disease; he had scarcely ever known it fail to arrest this fearful disease in a flock of sheep.

Mr. WALLIS wished to know whether the lambs in Wiltshire suffered from scour before they died so suddenly?

Mr. WILLIAMS said there was not the slightest approach to scour, although it was called so. The most pratical farmer, in looking at his flock over night, would be unable to discover any symptom of disease; in the morning the animal was dead, and a little mucus was found to have escaped. The case was evidently one of rapid inflammation.

Mr. WALLIS had understood Mr. Williams to speak of sainfoin as a certain remedy for scour.

Mr. WILLIAMS said they called it scour, but they never saw the scour till death; it always came away with the life of the animal.

Mr. J. G. KING (Beedon, Newbury) said: Having lost a great number of lambs within the last fortnight, he had hoped that some gentleman present would have been able to tell him how he ought to treat his lambs. One mode of treatment had been suggested which he had himself adopted, and which certainly had not proved a preventive. He had allowed a flock of lambs this season to run over two or three fields of wheat, and the result was that he had lost more of those lambs than of the lambs which had been shut in.

The Rev. C. T. JAMES said the subject of the treatment of lambs was essentially connected with that of the condition of the ewe. No child could ever be reared well if the mother from whom it obtained nourishment was at the time of affording it in bad condition. There was one point

to which he was particularly anxious to direct attention. They all knew that this had been a great year for lambs, the number of couples being very great. Now his own experience went to show that where there was a couple of lambs there was much more disease and liability to death than where there was a single lamb. He had observed that the teats of ewes which had two lambs got into such a state, that their appearance resembled that of smallpox in the human being, and that this was not the case where there was only one lamb. He thought a great deal of harm was done by the excessive interference of many shepherds in the way of manipulation with regard to the ewes. It would in most cases be far better to leave nature to herself.

The CHAIRMAN said he had very little to add to what they had already heard. Mr. Marshall had given them a very excellent paper, but the disease to which he referred must be a very different one from that which prevailed in his own locality. Mr. Wallis spoke of low feeding as one cause of disease; now he always considered sheep highest fed were most subject to be attacked (Hear, hear). He thought that the state of the blood had a great deal to do with the matter. As intimated by Mr. Williams, he had lost a great many lambs from disease. He lost as many as seventy in one field in fourteen days. His losses generally occurred at quite a different period from that mentioned by Mr. Marshall; they occurred when the lambs were from six to twelve weeks old. He quite agreed with Mr. Williams that the food of the mother was the great source of the disease and that the only means of avoiding it therefore was to wean them early. The lambs that died were all taken off in the same way. He never saw one recover after being affected. The chief symptoms were a slight foaming at the mouth and a nodding of the head as if the animal were feeding. His sheep had not escaped; he had something like 200 sheep feeding in yards at that moment, and he had lost fourteen of the flock since he put them there. He agreed with Mr. James with regard to the great loss which was generally sustained where double couples. He had lost from thirty to forty lambs that were twins; and, as regarded his ewes, while on the one hand he had lost upwards of thirty ewes that brought two lambs, he had lost only two ewes that brought a single lamb. In February the twins came very thick, and the ewes being short of milk he had recourse to cow's milk to make up the deficiency. The lambs (being all double couples) continually sucking, and from the sharp and cold east winds, the ewes' udders became sore, and the lambs had bad mouths, so much so their lips were three times as thick as they should be, and the teeth projected in front. He used alum and treacle, but was obliged to call in veterinary surgeon who pronounced it small-pox. It certainly had every appearance of small-pox, the udders being in spots, all sores and a scab. They were put by themselves in warm yards, dosed and ointment applied till cured.

Mr. MARSHALL then replied. There appeared, he observed, to be the greatest difference between the system of managing lambs adopted in the West of England and that adopted in his own part of the country. He did not at all agree with Mr. Wallis that over-stocking was the cause of his losses. Last year, when he lost the greatest quantity of lambs that he ever lost in his life, his pastures were exceedingly good. As regarded the changing which was suggested, he took it for granted that if they had a quantity of sheep that were doing badly a change must be desirable. In Lincolnshire, however, they never changed the sheep which were depastured upon seeds. When they were taken out of the lamb-yard they were put upon a field of seeds, and were never taken out of it till they were weaned. As regarded the quality of the grazing land of North Lincolnshire, he must say it was naturally almost as poor as any on earth. He concurred in what had been said with respect to the value of sainfoin. He had himself a field of sainfoin, and he never saw his sheep do better than they did on that. Whenever any of them were attacked with diarrhœa he put them on sainfoin, and they were cured within a week. It was to be regretted that no gentleman had given them the result of a *post mortem* examination of any of the lambs that had died in Berkshire or the West of England. Mr. Williams had made some interesting remarks as to the symptoms of the disease in his own locality, but he had not said anything which tended to show what the disease arose from. As to the diseased udders, of which Mr. James had spoken, having himself long suffered from that cause, he could assure him that the evil was not confined to ewes that had pairs of lambs (Hear, hear). He had seen that malady among his flock as many as fifteen or twenty times this year, and it prevailed quite as much among sheep that had only one lamb as among those that had two lambs. He never observed any difference in that respect. There was a very good cure for that malady—an ointment which was sold in a market town of Lincolnshire. If that ointment were applied to those parts of the udder which were cracked, the application was sure to effect a cure within two or three days.

The Rev. C. T. JAMES: Can you give the name of that ointment?

Mr. MARSHALL named Mr. Cartwright, of Horncastle, as the only druggist from which the ointment could be procured.

Mr. WILLIAMS (Baydon) wished to be allowed to make one observation in reference to what had fallen from Mr. Marshall about a *post mortem* examination. He thought that was a matter which had been too long neglected; and he was convinced that if some dead lambs —say five or six from different farms—were sent to the Veterinary Professor of the Royal Agricultural Society for examination, he would with great pleasure do what was required.

Mr. CORBET observed that the Professor had asked for them over and over again.

Mr. WILLIAMS trusted, then, that something would soon be done in the matter (Hear, hear). All he could say on the subject was that the disease was an exceedingly rapid one. When the shepherd left the flock in the evening, the animals appeared quite well; the next morning they were dead. On cutting some of them open, he had found the bowels void of food, and in a high state of inflammation. All the smaller bowels of the animal were filled with a nasty-looking fluid, as red as

blood. He thought they were all greatly to blame for not having taken proper steps to ascertain the cause of the disease, as that might have led to the discovery of a remedy.

Mr. WALLIS said, he appeared to have been misunderstood both by Mr. Marshall and by the Chairman. They appeared to have supposed that he advocated uxuriant pasturage. Now he did nothing of the kind. What he contended was, that they should not keep so many sheep per acre on the land, but that they should have a given number of cattle with the sheep, in order that the two together might keep down the pasturage. He never saw good management where the pasturage was rank.

Mr. TRETHEWY moved a vote of thanks to Mr. Marshall for his excellent introduction.

The Rev. C. T. JAMES in seconding the motion said, he believed the reason why there were not more flock-masters present, was that it happened that several of the great sheep fairs were being held at that time.

The motion was then put and carried unanimously.

On the motion of Mr. LITTLE, seconded by Mr. MARSHALL, thanks were also voted to the Chairman, and with this the proceedings terminated.

IRISH AGRICULTURAL STATISTICS.

We give the following Tables from a return which has just been presented to both Houses of Parliament, by the Registrar General for Ireland. There are other valuable Statistical Tables contained in the series, but we think those we have selected will be found most instructive and interesting :—

TABLE OF THE ACREAGE UNDER CROPS, THE ESTIMATED AVERAGE PRODUCE PER STATUTE ACRE, AND THE TOTAL PRODUCE OF IRELAND IN 1856 AND 1857.

Crops.	Years.	Extent of Crop.	Average Produce per Statute Acre.	Estimated Total Produce.
		Statute Acres.	Barrels, 20 stones.	Quarters.

COLLECTIONS OF PRODUCE AND ANIMAL FOOD.—THE KENSINGTON MUSEUM.

We have from time to time drawn attention to the various efforts making to develop the industrial products and also the economic uses of plants and animals. Every step in this direction, properly carried out, is calculated to be of eminent benefit in a national point of view, in diffusing sound practical information, and in developing that kind of knowledge which tends greatly to promote the more extended application of known products, as well as the introduction and experimentalizing on or trial of new ones. In the metropolis we have already three important collections, all rapidly increasing, and which, even in their present condition, are highly useful for study and investigation.

The Museum of Economic Botany at Kew, under the able superintendence of Sir W. Hooker, has already attained to an eminent position for amount and variety. The new museum building has given greater space for the display of specimens; but is already full, and proves how rapidly any such collections grow, when once commenced. The distance, however, shuts it out from ready access for reference by the merchant, the broker, manufacturer, or cultivator. Moreover, the strictly scientific classification into botanical groups, families, and orders, renders it difficult for any but a well-informed botanist to find out and compare plants and products of a similar character. Thus, any one interested specially in gums, fibres, woods, or food-products has to wander over very many rooms and examine scrupulously dozens of cases to obtain the information he is in search of.

Another diversified trade collection has been formed by the Crystal Palace Company in one of the upper galleries of the building at Sydenham. But the visitors seem to be totally unaware of it, and its isolation and remoteness draw few to the inspection.

The East India Company's new Museum is another step in the same useful direction. The Directors have collected from the length and breadth of their vast territories samples of everything that is commercially useful, whether of merely local use in the East or forming articles of trade. And certainly, amid the glitter and gorgeous splendour of Eastern jewellery shown, the raw products in the galleries form by far the most important feature for careful study and inspection.

The Royal Agricultural Society of England has taken no step towards forming any collection of agricultural produce, indigenous or foreign. In this it is at least behind the French, American, and other similar societies. The cultivation, manufacture, and preparation of the ingredients for our daily bread are among the most important investigations which can occupy attention.

The interest which may be given to a scientific investigation of the most ordinary matters of everyday life is shown by the popular disquisitions into the "Chemistry of Common Life," by the late Professor Johnston. A consideration of this matter has doubtless induced Dr. Lyon Playfair to add a food department to the trade gallery of the South Kensington Museum, which already, under his indefatigable scientific supervision, has grown to very respectable proportions, and bids fair, as a whole, to form one of the most interesting and nationally useful features of that branch of the Science and Art department. It will form a model well deserving imitation in the provinces and in other countries. The arrangement and classification adopted are, first the collection and display of the principal articles of animal food as far as these can be shown; next the cereals, including all the leading varieties grown here or elsewhere, and the products obtained from them. The collection is particularly interesting in the samples of maize, millets, rice, and other grains, not much seen in this country. There is also a very large and fine collection of leguminous grains and pulse, including the chief varieties of lentils and lupins, chick peas, and so on. The roots, tubers, and bulbs, botanically arranged, follow next in order, succeeded by the vegetables of which the stalk, leaves, or top are eaten. We then pass on to the fruits cultivated in this country or imported, and the fruit products. Another group is devoted to the esculent flowerless plants, a division of which too little is known; such as the mushroom tribe, lichens, and algæ, very many of which serve as portions of food in different countries. The sugars, starches, gums, and vegetable extracts, form another very important division, full of instructive information by means of descriptive labels and printed particulars, although several of these are only yet in the course of arrangement. The vegetable fats and oils, essential or solid, used in confectionary and for alimentary purposes, come next, and are followed by a fine collection of condiments, spices, and aromatic flavouring herbs. The substances used for making warm infusions or beverages follow, and are illustrated by diagrams of the plants producing them, by all the commercial varieties, and by chemical analyses. A curious feature in the collection is the various narcotics, masticatories, and intoxicating drugs used in different countries, showing the depraved taste for stimulants, which, in one form or other, seems universally to prevail. And, lastly, we have the different fermented liquors—the beers, the brandies, the wines, and other prepared drinks.

One of the most important features for study in the food section is the chemical analysis of each particular article, whether grain, pulse, root, or leaf, used for dietetic purposes. Those even who have no general knowledge of chemistry can here gain a popular and correct idea of the nutritious and useful parts of food.

and learn something of the heat-giving and flesh-forming components; and thus comprehend why particular kind of food have been used from time immemorial by particular nations. The proportions of fat, gum, sugar, and starch, and of mineral substances and fibre in each, are here specially shown in their due proportions in a given amount; and are therefore more easily understood and impressed on the mind by the eye than through the mass of per-centage figures and symbolical characters usually given in works on chemistry.

We have been able to give but a bare enumeration of the nature of the collection. This is as yet in an incomplete state, owing to the time required in obtaining and arranging specimens, and analyzing products, as well as from the fittings not being yet complete. But we shall return to the subject when the collection is in a more advanced state. The ideas, plans, and development are highly creditable to Dr. Playfair's comprehensive genius; and while these will prove of great public importance in diffusing useful information, they will also add to his already well-established reputation as an eminent chemist.

ORIGIN OF THE DUCHESS FAMILY.

SIR,—I believe I can supply some facts respecting the origin of the first cow recorded in the Duchess pedigree, alluded to by your correspondent DUNELMENSIS, in his interesting letter of the 19th, which not being generally known, may interest your readers. Your correspondent says: "We are not aware whether the cow by Mr. J. Brown's red bull was purchased or bred by him. (I imagine from the context that your correspondent here alludes to Mr. Colling.) Assuming the former to be the case, which we believe, she belongs to the class of cows having pedigrees when he bought her; though of whom he did so, we are also ignorant."

I have in my possession a catalogue of a sale of shorthorns, belonging to Mr. George Vail, of Troy, U. S., to which, in addition to the usual particulars, that gentleman enters into details respecting the mode in which he first acquired the originals which he imported from England. These were Duke of Wellington, roan bull, bred by F. Bates, Esq., by Short Tail (2621), dam Oxford premium cow, &c.; and Duchess, white heifer, also bred by Mr. Bates, got by Duke of Northumberland (1940), dam Nonsuch the Second, by Belvidere (1706), &c. He then appends the following interesting account of the origin of the Duchess family, which, as will be seen, purports to be given by Mr. Bates himself. Mr. Bates bases the superiority of his shorthorn cattle upon the merits of what he terms his "Duchess tribe," and in his communication to the publishers, of his premium bull, Duke of Northumberland, he remarks, "The whole of this family of shorthorns are alone in my possession, having purchased my original cow of this tribe, of the late Charles Colling, Esq., of Ketton, near Darlington, thirty-five years ago. They had been in the possession of Mr. Colling twenty years, who purchased his original cow of the agent of the late Duke of Northumberland, and called her Duchess (which is the reason I have named the bull after that family), as they are justly entitled to be held in commemoration for having possessed a tribe of cattle which Mr. C. Colling repeatedly assured me was the best he ever had, or ever saw, and that he never was able to improve upon her, although put to his best bulls; and I have undoubted information from the best authority for saying that this tribe of Shorthorns were in the possession of the ancestors of the present Duke for two centuries; and that Sir Hugh Smythson, the grandfather of the present Duke, kept up the celebrity of this tribe of cattle by paying the utmost attention to their breeding, and that he used regularly to weigh his cattle, and the food they ate, so as to ascertain the improvement they made in proportion to the food they consumed."

Respecting the authenticity of the foregoing, I need only remark that the name of Mr. Vail, appended to the entire document from which it is extracted, appears to be a sufficient guarantee. The date of the handbill is May 14th, 1849.

The Duchess family would thus appear to have been bred with care at a period considerably antecedent to that usually assigned as the origin of the improved Shorthorns. More is known of its origin than is the case with most others, even of the most celebrated originals of the race. We also find that Mr. Colling expressed a high opinion of this family at a period long antecedent to that of their being crossed with Belvidere. Indeed, the very considerable price which Mr. Bates paid for the Duchess which he bought at Mr. Colling's sale, affords a strong presumption that she can have been no ordinary heifer. Of course, in speaking of events which occurred long before my own recollection, I am dependent upon the evidence of others. Subject to this proviso, then, I may state that I have it upon the authority of one who well knew the Duchesses in early days, that as a family they always possessed the high quality which characterises them at the present day. My informant, however, adds that the cross with Belvidere appeared to impart to them a character of majesty, strongly exemplified in the Duke of Northumberland, which now seems as peculiarly to distinguish the bulls as refinement does the cows. At all events, this, like every other important cross to which Mr. Bates resorted, has been stamped with the approval of the public, including the remarkable one with the blood of the Matchem cow. Not only have both bulls and cows of the Duchess family realized prizes, which taken one with another may be termed unprecedented, but other animals have by means of a few crosses of this blood, in spite of short pedigrees, been sold for more money than best blood of other families was apt to command Thus, at Mr. Tanqueray's sale in 1855, three cows and

a bull of the Oxford family (descendants of the Matchem cow) realized 1,100 guineas. Yet the pedigree of this family is not traced further back than Young Wynyard (2859). Is this preference for Mr. Bates' blood, and especially that of the Duchess tribe, a mere caprice on the part of the public, or is it founded on reason?

As far as I am competent to form an opinion, I certainly think the Duchess tribe possess in an eminent degree those qualities which are desirable in improved cattle. Indeed, when the buyers of the world are congregated together, it will generally be found that their judgment is right. The question then arises, wherein the peculiar merit of Mr. Bates' stock consists? Mr. Bates required a short-horn to present a *union* of good qualities, instead of, like too many breeders, developing one or two points out of all proportion, while sacrificing others equally valuable. Beginning with the Duchess heifer, he endeavoured to establish a family, every member of which should as nearly as possible approach the type of a true short-horn. That they possessed both symmetry and early maturity, is attested by the numerous premiums which they won at the meetings of the Royal and other agricultural societies. The Rev. H. Berry mentions the Duchess tribe along with that of Daisy, as remarkable for their milking powers. Mr. Bates, however, soon arrived at the conviction that the degree of forcing which is necessary to command success in the show-yard, is highly prejudicial to a breeding herd; and he consequently discontinued the public exhibition of his stock. It is possible that the fine quality for which his herd and its descendants are remarkable may be in part owing to his judicious treatment, in keeping his stock generously without forcing it unduly. Since his death, and its consequent dispersion, its value has rather increased than otherwise, as witness the marvellous Tortworth sale, and that of Mr. Tanqueray. In public competition, too, this blood has been eminently successful, whether in conjunction with other blood, like Mr. Ambler's Grand Turk, or unalloyed like Lord Feversham's Duke of Oxford.

I should be sorry if it were to be imagined from what I have just written, that I am so bigoted an admirer of the Duchess blood as to be insensible to the merits of any other. I am sure that all who are acquainted with my writings will bear witness that I have never hesitated to commend whatever strain of good blood has been brought under my notice. I hold it, indeed, to be a besetting weakness of breeders to persuade themselves that all blood is worthless except that which they themselves possess. Singularly enough, too, the more decided success a man has achieved, the stronger is his temptation to follow this delusion. It is after he has attained his idea in practice, that the danger besets him of being so satisfied with what he has accomplished, as to imagine that further exertion is unnecessary. He is too apt to forget that the very eagerness with which he has cultivated certain favourite points, has led him to pay less attention to others no less essential. It is thus that deficiencies become no less stereotyped in certain strains of blood than their merits. However trying, therefore, it may be to the feelings of a breeder to resort to other blood, whoever wishes to maintain his stock at the highest pitch of excellence, must from time to time have recourse to a cross as far removed from his own as is compatible with purity. There is no difficulty in making a selection from the numerous families which are descended from the times of Colling and his contemporaries. And the letters of *Dunelmensis* afford much useful information to those who desire to become acquainted with the annals of those early days.

In another respect your correspondent is doing good service, viz., in stating the real facts of the case with regard to the origin of the improved shorthorns. It is important that it should be generally known that long before the time of the breeders contemporary with Charles Colling, who have now attained world-wide celebrity, there was an excellent breed of cattle in existence in Durham and considerable districts of Yorkshire. It is important to have the authority of your correspondent in support of the fact that selection from the materials around them was the principal foundation on which the wonderful fabric of the shorthorn race has been reared. It is satisfactory to know that they are not, as has been sometimes affirmed by parties ignorant of those districts, an artificial product, patched up by the forced union of many incompatible races. That Mr. Colling did introduce into part of his stock a cross with the Galloway cow is well known to every person even moderately versed in the history of his proceedings. If there had been any doubt upon the subject, it has long since been set at rest by the inquiry which the late Lord Spencer caused to be made among the papers of that eminent breeder. But although an incident like this strikes the imagination of persons not practically versed in breeding, and is admirably suited to the purposes of bookmakers who copy it from each other, to the neglect of more important matters, it is absurd to attribute to this cross the origin of the improved shorthorns. No one can read an authentic account of the manner in which Mr. Colling introduced the foreign blood, without being struck with the judiciously sparing measure in which he used it. Permanent excellence in a breed was never yet attained by the crude union of incompatible qualities. It is only to be looked for from the judicious selection of individuals characterized by those properties which we desire to perpetuate.

I am yours, &c.,

Holly Bank, April 26. WILLOUGHBY WOOD.

THE FATE OF THE STATISTICS BILL.

We are inclined to believe that Mr. Caird really meant well with his Agricultural Statistics Bill. It read, moreover, as a measure framed in all moderation, and calculated to work easily with those to whom it was intended to apply. Unfortunately, however, the proposition came from the wrong quarter. There was a Doctor Fell feeling about its introduction that it was not very difficult to understand. It is not so very long since the honourable Member for Dartmouth was in something like open antagonism with the general body of agriculturists. As the model Free-trade farmer and special Commissioner, the Country party may have thought they had little to thank him for. He is going to put some more cross questions, and will be trying to show us up again, no doubt.

The signal defeat of the Statistics Bill must be in a great degree attributable to this. Of the bill itself, we repeat, there is very little to complain; and on its own merits, we confess, we do not see why such a plan should encounter more opposition in England than it has done in Scotland or Ireland. But it was made a party question. The representatives, indeed, of the agricultural interest appear to feel far more acutely in the matter than the agriculturists themselves. Even the leader of this opposition, Mr. Packe, is subject to continual correction when he touches upon the subject in his own county. Almost the only practical farmer examined before the Lords' Committee spoke directly in favour of the collection of these statistics, while Mr. Bankes Stanhope, who represents him in Parliament, is as decidedly against them. Mr. Ball, again, the member for Cambridgeshire, will not have such a system on any terms, while some of the warmest of his supporters stand committed to its advocacy. Still, even the landlords do not all pull together here. There is, perhaps, no man in the House who takes a greater interest in the cause, or who understands the farmers better, than does Mr. Miles, the member for Somersetshire. We can all remember how excellent a President he made of the Royal Agricultural Society. Mr. Miles voted for Mr. Caird's Bill. "He was astonished that it should have met with so much opposition. He was in possession of facts which proved that the agricultural interest did not offer the slightest objection to making returns, so long as they did not interfere with produce and stock." Mr. Caird did not propose to interfere with produce or stock. Then, Mr. Henley is in favour of what he calls "pure statistics"—of the acreage, that is—"the only thing that is really valuable." Mr. Caird asked for no more. These, be it borne in mind, are two leading members of the Conservative cause; both with high characters in their own homes as good landlords, and both with a sound and practical knowledge of the question. They may differ in some minor matters of detail; but, as far as the object and the principle is concerned, they go thoroughly with Mr. Caird.

Now, had Mr. Miles or Mr. Henley introduced this measure, we cannot help thinking it would have met with a very different fate. Let us remember, and take example from what has been already accomplished in this way. What was the great secret of success in Scotland? Simply the fact of the point being put to the farmers by those they knew and could trust in. It is absurd to suppose the system, if only properly introduced, would not work as well here. When we know already that on the first time of asking so 'cute a constituency as the Yorkshiremen, ninety-nine out of a hundred, filled up the returns, it is idle to question the practicability of such a plan. But unfortunately our own national Society would not make the effort. That terrible "Charter" once more stood in the way. Still, any known man might have done it. We give Mr. Caird every credit for his intention. His work, in short, speaks for itself. He must know, however, that his name is scarcely palatable in a certain quarter; and that, perhaps, few in the House would tell less favourably when taking a lead in rural affairs.

In a somewhat lengthy discussion which ensued on the motion for this second reading, there was in reality very little advanced against the principle. Mr. Packe seemed to think the farmer is the only man asked for this kind of information; whereas there is scarcely a calling but has to give it. In almost every branch of trade returns are made. The stocks of sugar, tea, and other articles, are exactly known; as well as what is on shipboard, and what is to be expected. Agents are sent to America to traverse the cotton producing districts, and make estimates of the growing crop. A shipowner states the number of his ships, and their tonnage—what he gave for them, and what he may have borrowed on them. But no government thinks of these returns singly and separately. It is the gross amount that is required. Besides, is there any business in which the individual detail is so easily known as the farmer's? Would a landlord or agent go to the acreage return to know what the tenant is doing? And, does not the village parliament make out its own return week by week, and year by year? What I have in wheat, you in beans, and he in barley. "When," says Sir Cornewall Lewis, "this question was first brought forward in this House it was met by several hon. members—as it has been by some hon. gentlemen who have spoken to-day—with objections which I cannot help characterizing as partaking of the nature of prejudice and clamour; I allude to those objections founded upon the alleged inquisitorial visitations to which a system of agricultural statistics would give rise, and the compulsory means of information to which, under its operation, it would be necessary to resort. When this question was first

mooted a general impression prevailed among the farmers of the country that it was intended to devise some new means of taxing, or of enabling their landlords to raise their rents. Their fears upon these points, however, appear to me to be wholly chimerical and illusory. Nobody can demonstrate how the Government would be provided with an additional means of taxation by obtaining this statistical information; nor does it seem to me that the landlords can fairly be supposed to have that very imperfect knowledge of their own estates which would render it probable that the meagre and unsatisfactory returns which we might hope to obtain in reference to agriculture would place them in a different position, so far as the question of raising their rents is concerned, from that in which they now stand. I cannot help thinking, therefore, that the fears to which I have referred are wholly unfounded; and my experience tends to convince me that they are now very much dissipated, and are not shared in by the more intelligent members of the agricultural classes."

Again, can any one imagine such a plea against the collection of statistics as that offered by Mr. Drummond?—That this was information only useful for the corn-dealer, and that the farmer should not be encouraged to hold back or sell, but be left to dispose of his produce as his necessities required! The answer to so manifest an injustice is self-evident; but it was well put by Mr. Cardwell:—"He held a higher opinion of the farmer than his hon. friend, who thought he must only conduct his business on the hand-to-mouth principle, and only go into the market to sell his produce under the immediate pressure of necessity. Pursue that train of reflection, and they would see that the British farmer was of all others the most interested in the collection of agricultural statistics. The persons with whom he made his bargain usually conducted their business on a great scale, but the farmer had only the produce of his own farm to sell, and could have little or no knowledge to guide him except that which the Legislature might afford him. If, as they had just heard, a large purchaser of barley (Mr. Bass) could tell them that it would be of the greatest interest to him, in his trade, to have a collection of agricultural statistics; if, with all his means and intelligence, he would be glad to have such information as he had referred to, how much more glad would be the farmer who dealt with him?"

Mr. Du Cane quoted evidence to show how impossible it was to make anything like an accurate estimate of the yield—which we entirely agree with; *only* the Bill before the House did not ask for such an estimate! So good a man as Mr. Ker Seymer had to content himself with such mild pleasantry as this (he is speaking for his tenant):—"I am busy growing corn; you ask me to fill up schedules; I would rather grow my corn, if you please." And Mr. Bentinck thought the effect of the Bill would be to encourage a vicious spirit of speculation amongst the farmers. Mr. Henley, while admitting the principle, made endless objection to the details of the plan by which this information is to be obtained. We are by no means ready to pass the machinery of the proposed Bill as anything like perfection. Sufficient, however, has already been done, even in England, to show that many of the obstacles the right honourable the President of the Board of Trade would raise are hardly worth consideration. Nothing is so easy as to anticipate such difficulties; but they smack here chiefly of red tape, and "how not to do it."

A far more important point is, what these returns would be worth when obtained? Would they justify the expense of making them, either to the producer, the people, or the Government? In answer to this we have already evidence as to how interesting and useful they have been in demonstrating the improvement of Ireland. They were working on to the same end in Scotland. That their collection here would be followed by any immediate sign or effect we much doubt; but that they would gradually be developed into a very serviceable guide and test of our condition we doubt very little. We believe, moreover, that such information might, if only judiciously worked, be had at little trouble and expense. The farmer himself has in a great measure outlived his prejudice; while the experience of his brethren over the Border and across the Channel will assure him how little there is in reality to fear.

THE PESTS OF AGRICULTURE.

Of the many subjects possessing a primary interest to the agriculturist, certainly the depredations committed upon his crops and produce by insects and vermin are not the least important; nor is the consideration of this matter alone of interest to the farmer. Every individual, here or elsewhere, is at times the prey of blood-thirsty vermin—a safeguard against whose voracious attacks would be considered a veritable boon both to individuals and to society at large. Bipeds and quadrupeds, animals and vegetables—all have their predatory enemies and parasites, for which, despite the "*catch-'em-alive-o*" fly-papers, the insect-destroying powders, and other alleged specifics, we have as yet no remedy. Many of the plagues of Egypt are still permitted to annoy our persons and destroy our crops.

Although at home wasps and flies are occasionally sad tormentors, and the blood-sucking pests of our lodging-houses and dwellings leave unpleasant reminiscences behind, it is only those who have seen animal life in all its profusion in the tropics who know the intense horrors and inconveniences of insect pests. There swarm mosquitoes, buffalo gnats, small black flies, horse-flies, minute sand-flies, flights of locusts, chigoes depositing their nidus in the flesh, the guinea-worm

tormenting one by getting under the skin. Rest is banished during the sultry hours, for the human subject; while cattle, horses, and domestic animals generally are worried so that they can neither feed nor rest. Flies get entry into your mouth, into your eyes, into your nose. You eat flies, drink flies, and breathe flies. Lizards, centipedes, cockroaches, and snakes get into the bed; ants eat up the books; scorpions sting you on the foot. Everything bites, stings, or bruises; every second of your existence you are wounded by some piece of animal life that is new to you. An insect with eleven legs is swimming in your teacup; a nondescript with nine wings is struggling in your beer; or a caterpillar with several dozen eyes in his belly is hastening over the bread. All nature is alive, and seems to be gathering all her entomological hosts to eat you up, as you are standing out of your coat, waistcoat, and breeches. Such are the tropics. Even in parts of North America, a resident tells us—"If you would sleep on a sweltering night in June, nothing short of chloroform will render a novice insensible to the melody of those swamp serenaders, the musquitoes, or the tactics of their bloodthirsty ally, the black fly, who noiselessly fastens upon your jugular, while the musquito is bragging in your face. Two remedies are at your service, either of which some persons will be found captious enough to consider worse than the disease. The first cure is the one applied to hams—smoke yourself until your eyes are like burned holes in a blanket, and you have creosote enough in your mouth to cure a toothache. The second is to smear all your assailable parts with Canadian balsam, until, after a night's tossing in your blanket, you have wool enough on your face and hands to make you look, as well as feel, decidedly sheepish."

It is, however, with the pests of agriculture that we are specially interested, and to which we would direct attention. Here is a subject to which the Royal Agricultural Society might well devote itself, by bringing to bear on it the more extended practical observations of the farmers and the investigating skill of scientific men. Too little has yet been done on a broad scale in this direction. Entomologists have taken up occasionally the investigation of one or other of the predatory insects; but there are few collected details, or scientific examinations. With the exception of Kollar's work on Insects injurious to Agriculture, and Mr. Curtis's essays (there is one very excellent one in the last volume of the Journal), we do not know of any special treatise that enters into detail on this important matter fraught with such larger interests and high importance. Among the officers belonging to the Royal Agricultural Society, we do not find, as in the New York and Paris societies, an entomologist, and yet the agricultural crops of various kinds are even of a higher importance than the live stock. If we have a veterinary professor for the one, surely the ravages committed by insects on the other demand the supervision and scientific examination of an entomologist to point out the habits of the insects, characteristics, and remedies.

The American Legislature votes £200 a-year to promote the investigations of Dr. Asa Fitch, Entomologist of the New York State Agricultural Society. A most useful collection of insects hurtful to agriculture has been formed under his supervision, and much useful information obtained and promulgated. M. Edwards, the administrator and curator of the Collection of Entomology at Paris, recently sent over to the New York society a collection of the predatory insects from Algiers. In parts of Canada and the United States great ravages are occasionally committed by three distinct insects destructive to the wheat crops, which in name, at least, are often confounded—the Hessian fly (*Cecidomya destructor*), the weevil, *Calandra granans*), and the wheat midge, or wheat gnat (*Cecidomya tritici*). Almost every local society abroad is doing something in this direction; but their labours want collecting, to be of general use. The Agricultural Board of Canada recently devoted £80 in premiums for the best essays on the origin, nature, habits, history of the progress from time to time, and the causes of the insects, which ravaged the wheat crops. The South Australian and other agricultural societies have all moved in the same direction. To understand in their true extent the depredations of insects, we must not, as Mr. Spence observed some years ago, confine our attention to the hundreds of thousands of pounds which we annually lose from the attacks of the hop-fly, turnip-flies, the wire-worm, the weevil, and the host of insect assailants of our home agricultural and horticultural produce, but we must extend our views to the colonies and foreign countries. We shall there find that in Australia and British North America the potato crops are often, in some quarters, wholly cut off by the potato bug; that in the West and East Indies the cocoanut trees are the prey of a boring insect; that the cotton crops of India and America are frequently seriously injured by insects of various tribes, whose history we have yet to learn; that in Ceylon the coffee-bug commits sad depredations on the trees; that in the Straits settlements the spice-trees are much subject to the attacks of certain species of cocci; while in Africa whole tracts of country are devastated by swarms of locusts, although these are greedily seized on, in turn, as food by the natives. It would therefore seem that the vegetable world has plagues far greater than ever Moses inflicted on the inhabitants of Egypt.

We see, then, that insects are the most numerous, as well as the most destructive, foes to which the agriculturist is exposed.

As Loudon observed long ago, their species are so many, and their devastation so varied, that, without some acquaintance with their scientific classification, and a correct knowledge of their haunts and economy, their operations can neither be understood nor effectually counteracted.

What we desire to see is some good collection of insects, &c., and their injurious effects shown, which shall be available for reference both by the scientific man and by the farmer, gardener, and tropical cultivator. At present we have nothing of this kind on a respectable

or useful scale. The Entomological Society's operations are extended to all classes of insects, and not specially directed to those injurious to agriculture. At Kew Sir W. Hooker has introduced to some small extent the insects which prey upon trees, &c, and the effects and diseases are partially shown.

Dr. Lyon Playfair, we believe, contemplates collecting, and exhibiting in the Food Department at the South Kensington Museum, specimens of the insects injurious to animal and vegetable products. But while these are auxiliary steps in the right direction, we should like to see a more concentrated course of action, and special and continued attention given to this matter by the Royal Agricultural Society.

Let that body put itself in communication with the provincial, colonial, and foreign societies, and solicit their aid in replying to queries and furnishing specimens; and contributions of a very valuable character would soon be amassed, which, when arranged, compared, and described by a competent entomologist, would result in large practical benefit, not only to our own country, but to the world at large.

We have hitherto stood high in our science and practice in all departments of agriculture; let it not, therefore, be a reflection on us that other countries are more energetic in this minor, but very important, matter. No one can fully estimate the heavy periodical losses inflicted on cultivators, in gardens, fields, and plantations, by the insect pests to which we have alluded.

ROYAL DUBLIN SOCIETY.

SPRING CATTLE SHOW.

This meeting took place under very favourable auspices on Tuesday, Wednesday, Thursday, and Friday, April 27, 28, and 29. It was pronounced to be one of the best exhibitions of stock ever seen here. The Shorthorns came out very strong, and were beyond all praise—134 yearling bulls. We subjoin the list of prizes, and though, generally speaking, these were well awarded, they as usual did not properly distinguish between fat and good store condition. Mr. Douglass' bull and heifer were perfect animals, but we much doubt if they will ever be very large. Mr. Barnes' yearling bull was not so fat, but a beautiful even beast, and sold at a very large sum, though not named by the judges. Many of the best judges pronounced Mr. Christy's two-year-old bull superior to Master Butterfly: he will be sold for a large sum. Lord Clarina had a nice heifer, but only in store condition: Mr. Massy refused 70 guineas again and again for her. Mr. Turner's cow was as near perfect as anything ever seen. Lord Waterford bought her and her fellow for a great sum. The beauty of the Shorthorn stock was the common talk. The half-bred class shows their value as a cross—they are noble animals, of vast size and weight. The long-woolled sheep were largely represented, but not of very great merit; although Mr. Thunder's Leicesters were of fine quality. Mr. Beale Brown's ram lambs were of large size, constituting a portion of 70 of those, we understand, he has challenged the world with for a thousand pounds. Mr. King Harman's ram was a very even animal. The pigs were well represented, and, as usual, very good.

His Excellency the Lord Lieutenant, in a very good practical speech delivered at the evening meeting of the Society, thus touched on the merits of the show:—"I believe, without flattery, it is a show equal to, if not surpassing, any show of the sort which has taken place in England or Scotland. As regards the class of shorthorns, I am informed—and certainly my recollection bears me out in all the shows I have ever seen—that in Ireland this is the largest and best show that has ever taken place; and certainly I can confirm it as regards my own experience even in other countries. On looking at the animals which I had the satisfaction of witnessing to-day, I confess that I never have yet seen anything which gave me greater pleasure than the heifer belonging to Mr. Douglas—I believe as perfect an animal as ever has been shown at any agricultural meeting; and I am sure even an assemblage of Irishmen may pardon me if, following out Lord Clancarty's views, I do take a little national pleasure to myself, that that animal was accorded the first prize. Mr. Douglas has also carried off so many prizes that I will not go on with them too long; but I now come—I will not say with greater pleasure, but with more satisfaction to this company—to the Kerries. The Kerry cattle have long been the greatest possible favourites of mine. I think they are—if I may use the term—the thorough-breds of cattle. To my mind they are the most beautiful cattle I know. I saw some beautiful specimens of them to-day, and I believe it is as good an exhibition of this description of cattle as I have ever seen, and I admired them probably as much as any of you; and certainly in that respect no feeling of nationality came in my way. I also admired with feelings of partly pleasure and partly regret, the small stock of Devons, to which were accorded the prize, belonging to Lord Charlemont. I believe if there are any persons present who were present six years ago—I am afraid six years make a great difference — they will remember that I gave great praise to the pigs. It appears that during these six years the pigs have certainly improved. I do not think it possible to see a finer show, though I will not go the length of one of the stewards with respect to their private excellence, their domestic qualities, and their talents (laughter); but I admired them excessively. The only thing that gave me some degree of dissatisfaction was that there was not so large a show of Ayrshire cattle as I should have wished to have seen from my own country. What I saw were good, but I sincerely wish that the inhabitants of my country would pay more attention to your shows. It gives me great pleasure to see the progress that the Royal Dublin Society has made during the time I have been away."

THE PRIZE LIST.

JUDGES.

SHORT-HORNS.—Wm. Sanday, Holme Pierre Point; Mark S. Stewart, Southwick, Dumfries; Henry Croker, Croom.

MIXED BREEDS AND FAT STOCK.—Samuel Garnett, Robert W. White, C. G. Grey.

SHEEP.—Thomas Twitchell, Wellington, near Bedford; Captain Ball, Caleb Going.

SWINE.—Captain Edward Croker, Captain Arbuthnot, Henry Thurnall, Royston, Herts.

BULLS.

SHORT-HORNS calved in 1857.—First prize, 5 sovs., James

Douglas, Athelstaneford; second prize, Charles L. Ellison, 3 sovs.; third prize, Richard Featherstonehaugh, large silver medal.

Calved in 1856.—First prize, John Christy, 5 sovs.; second prize, Viscount Monk, 3 sovs.

Calved in 1855.—First prize, Lord Talbot de Malahide, 5 sovs.; second prize, George Roe, 2 sovs.

HEREFORDS calved in 1855.—The prize £3, Allen Pollock (no competition).

DEVONS calved in 1856.—First prize, £3, to the Earl of Charlemont (no competition).

Calved in 1855.—Prize of £3 to same.

BEST WEST HIGHLAND bull, of any age, Lady Pigot, large silver medal.

BEST SCOTCH POLLED bull, Lord Talbot de Malahide.

BEST AYRSHIRE bull, Wm. Boyle, large silver medal.

BEST ALDERNEY bull, Henry M. Barton, large silver medal.

BEST KERRY bull, Sir Edward M'Donnel, large silver medal.

Best bull of any breed, calved prior to 1855, Ambrose Bole, large silver medal. Second best, Nathaniel Barton, small silver medal.

Best of all the prize bulls, James Douglas, the gold medal. Second best, John Christy, large silver medal.

COWS AND HEIFERS.

SHORT-HORNED.—Best heifer, calved in 1857, Thomas Ball, large silver medal; second best, Thomas Barnes, small silver medal.

Best heifer, calved in 1856, in calf, or producing a live calf within twelve months subsequent to the 13th of April, 1858, James Douglas, large silver medal; second best, James Douglas, small silver medal.

Best heifer, calved in 1855, giving milk, or in calf, John J. Turner, large silver medal; second best, Wm. Owen, small silver medal.

Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Lady Pigot, large silver medal; second best, J. J. Turner, small silver medal.

HEREFORD.—Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Allan Pollok, large silver medal.

DEVON.—Best heifer, calved in 1857, Earl of Charlemont, large silver medal.

Best heifer, calved in 1856, in calf or producing a live calf within twelve months subsequent to the 14th of April, 1858, Charles Toole, large silver medal.

Best heifer, calved in 1855, giving milk, or in calf, Earl of Charlemont, large silver medal.

Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Earl of Charlemont, large silver medal.

WEST HIGHLAND.—Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, C. L. Ellison, large silver medal.

SCOTCH POLLED.—Best heifer, calved in 1857, Lord Talbot de Malahide, large silver medal.

Best heifer, calved in 1855, giving milk, or in calf, Lord Talbot de Malahide, large silver medal.

Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Lord Talbot de Malahide, large silver medal.

AYRSHIRE.—Best heifer, calved in 1857, William Boyle, large silver medal.

Best cow, of any age, in calf or having had a live calf within twelve months preceding the 13th of April, 1858, Wm. Boyle, large silver medal.

ALDERNEY.—Best heifer, calved in 1857, Jas. B. Kennedy, large silver medal.

Best heifer, calved in 1855, giving milk or in calf, James B. Kennedy, large silver medal.

Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Colonel Hill, large silver medal.

KERRY.—Best heifer, calved in 1857, Sir E. M'Donnel, large silver medal.

Best heifer, calved in 1855, giving milk or in calf, Hon. R. C. Talbot, large silver medal.

Best cow, of any age, in calf, or having had a live calf within twelve months preceding the 13th of April, 1858, Sir E. M'Donnel, large silver medal.

Best of all the prize breeding heifers, giving milk or in calf, James Douglas, the gold medal.

Best of all the prize milch cows, Lady Pigot, the gold medal.

Best three milch cows, in calf, or having had live calves within twelve months preceding the 13th of April, 1858, and *bona fide* the property of exhibitor, J. J. Turner, the gold medal.

The *Irish Farmer's Gazette* Plate, value £155—James Douglas, Athelstaneford, Drew, N.B., for his short-horned heifer Venus de Medicis.

FAT OXEN.

SHORTHORNED.—Best fat ox, calved prior to 1855, Nathaniel Barton, large silver medal.

HEREFORD.—Best fat ox, calved prior to 1855, Robert Smith, large silver medal.

DEVON.—Best fat ox, calved prior to 1855, Earl of Shannon.

ANY OTHER BREED.—Best fat ox, calved in 1856, Lord de Freyne, large silver medal.

WEST HIGHLAND.—Best fat ox, calved prior to 1855, David Rogerson, large silver medal.

KERRY.—For the best pair of fat oxen, of any breed, that have been fairly and *bona fide* worked as plough bullocks up to May, 1857, Earl of Shannon, large silver medal.

Best of all the prize oxen, Earl of Shannon, honorary certificate.

FAT COWS OF ANY AGE.

For the best Shorthorned, Nathaniel Barton, large silver medal.

For the best Devon, Earl of Charlemont, large silver medal.

For the best West Highland, John Fetherston, large silver medal.

For the best Kerry, James L. Napier, large silver medal.

For the best of all the prize fat cows, Nathaniel Barton, honorary certificate.

FAT HEIFERS.

For the best fat heifer of any breed, Nathaniel Barton, large silver medal; for the second best, P. J. Kearney, small silver medal.

SHEEP.

LEICESTERS.—For the best one-shear ram, George Thunder, three sovereigns.

For the best two-shear ram, same, three sovereigns.

For the best three hogget rams, never clipped, George Thunder, two sovereigns.

For the best five ewes, with their lambs yeaned in 1858, or in lamb, Livingstone Thompson, two sovereigns.

For the best five ewe hoggets, never clipped, William Owen, two sovereigns.

LONG-WOOLLED, not qualified to compete as Leicesters.—For the best one-shear ram, Thomas Beale Brown, three sovereigns.

For the best ram of any other age, Edmund Ruck, three sovereigns.

For the best three hogget rams, never clipped, Thomas B. Brown, two sovereigns.

For the best five ewe hoggets, never clipped, Edmund Ruck, two sovereigns.

SHORT-WOOLLED.—For the best one-shear ram, Charles W. Hamilton, two sovereigns.

For the best ram of any other age, Hon. L. H. King Harman, two sovereigns.

For the best three hogget rams, never clipped, Peter Broughton, two sovereigns.

For the best five ewes, with their lambs yeaned in 1858, or in lamb, Charles Wm. Hamilton, two sovereigns.

For the best five ewe hoggets, never clipped, Charles Wm. Hamilton, two sovereigns.

CHEVIOTS.—For the best one-shear ram, Lord Clermont, two sovereigns.

For the best two-shear ram, Marquis Conyngham, two sovereigns.

For the best ram, of any other age, Lord Clermont, two sovereigns.

For the best three hogget rams, never clipped, Lord Clermont, two sovereigns.

For the five best ewes, with their lambs yeaned in 1858, or in lamb, Marquis Conynghsm, two sovereigns.

For the best five ewe hoggets, never clipped, Marquis Conyngham, two sovereigns.

FAT WEDDERS.—For the best pen of five long-wolled fat wedders, not exceeding two shear, Sir Edward M'Donnel, large silver medal.

For the best pen of five short-wool fat wedders, not exceeding two shear, P. Broughton, large silver medal.

For the best pen of five cheviot fat wedders, Lord Clermont, large silver medal.

SWINE.

COLOURED BREEDS.—For the best boar, six months, and not exceeding twelve months old, Wm. Joyce, 3 sovs.; for the second best, Thos. Rutherford, 2 sovs.; for the third best, Lord Charlemont, the honorary certificate.

For the best boar, exceeding twelve and not exceeding twenty-four months old, E. W. Tomkinson, 5 sovs.

For the best boar, exceeding twenty-four months old, Arthur D. Chaigneau, 5 sovs.; for the second best, Robert Collins, M.D., 3 sovs.

For the best breeding sow in-pig, or having had a litter within six months, Captain F. Adey, 3 sovs.; for the second best, Major H. M'Clintock, 2 sovs.; for the third best, Capel F. Adey, the honorary certificate.

For the best three breeding pigs of the same litter, under ten months, A. D. Chaigneau, 3 sovs.; for the second best, Joseph Radcliffe, LL.D., 2 sovs.; for the third best, C. P. Leslie, M.P., the honorary certificate.

For the best litter of pigs, not exceeding five months old, accompanied by the sow, Robert Collins, M.D., 3 sovs.; for the second best, J. C. Metge, 2 sovs.

WHITE BREEDS.—For the best boar, six months, and not exceeding twelve months old, Lord Lurgan, 3 sovs.; for the second best, Charles L. Ellison, 2 sovs.; for the third best, Hans H. Woods, the honorary certificate.

For the best boar, exceeding twelve months, and not exceeding twenty-four months old, John H. Peart, 5 sovs.; for the second best, Wm. Boyle, 3 sovs.; for the third best, George Mungles, the honorary certificate.

For the best boar, exceeding twenty-four months old, Lord Lurgan, 5 sovs.; for the second best, Wm. Boyle, 3 sovs.

For the best breeding sow, in-pig, or having a litter within six months, J. L. W. Naper, 3 sovs.; for the second best, Wm. Boyle, 2 sovs.; for the third best, Robert W. White, the honorary certificate.

For the best three breeding pigs of the same litter, under ten months old, Charles L. Ellison, 3 sovs.; for the second best, James L. W. Naper, 2 sovs.; for the third best, Lord Lurgan, the honorary certificate.

HIGHLY COMMENDED.

BULLS.—J. Richardson, W. Coppinger, Lord Lurgan (2) W. B. C. Roberts, J. Barcroft, Major H. S. M'Clintock.

COWS AND HEIFERS. — Lord Lurgan, J. Barcroft, R. Campion, Thomas Barber, J. J. Turner, George Roe, Lord Talbot de Malahide, W. Boyle, Sir E. M'Donnel, R. G. Campion.

FAT STOCK.—Earl of Shannon, David Rogerson, Captain M'Clintock Bunbury, M.P., Sir Robert Paul, Bart., R. S. Fetherstonehaugh.

SHEEP.—William Owen, George Thunder.

SWINE.—Hans H. Woods.

COMMENDED.

BULLS.—Lord Dufferin and Clandeboye, Richard Chaloner, Thomas Barnes, John Christy, Thomas Barber, Hon. Thomas Preston.

COWS AND HEIFERS. — Lord Clarina, Thomas Barnes, Viscount Monk, Richard Welsted.

FAT STOCK.—Nathaniel Barton, R. S. Fetherstonhaugh, Allan Pollok, Earl of Clonmel.

SHEEP. — C. P. Leslie, M.P., William Owen, John La Touche, Ambrose Bole, Richard Byrne, Gustavus W. Lambert, John W. Brown, Lieutenant Colonel Tottenham, Marquis Conyngham, Lord Clermont, P. J. Kearney.

SPARE THE LITTLE BIRDS.

The augmented depredation of insects to which the farmers crops are subjected, amounting to an annual loss in value of millions sterling, and to the extent of nearly one-fourth in produce, renders the study of entomology almost a necessity: for, if without check this evil continues to increase, the day may come sooner than many will believe, when the important agricultural products will be so diminished from this cause alone, as to produce great dearth and suffering, and when many of the best and most valuable fruits will be a rarity, if their production is not rendered impossible. Note, in verification, all the varieties of the plum, gage, nectarine, and cherry fruit, which, from the ravages of the different genera of curculio, or the weevil, are now rare, and seldom come to perfection; and even one species of this destructive insect has lately deposited its eggs in the apple, and even in the peach. If this is to continue without effort at prevention or remedy, how soon may it be hopeless to look for, or even expect again to see, as in the days of old, the various fruit-trees breaking down from the burden of their golden and luscious fruit!

The evil is not done by the perfect insect—many insects never feed after their metamorphosis—but by the boring and deposition of the egg, which soon hatches, and we have a worm, or the larva, ravenous in its appetite, and destructive to anything it comes in contact with. The larva, or worm, does all the mischief by feeding on the fruit, thus destroying its organization; after which, of course, it soon drops to the ground, into which the grub or worm goes, and there hibernates until the ensuing year, when it revivifies, and comes forth the perfect insect at precisely the right time and season "to walk in the footsteps of its predecessors," and cause a greatly increased injury to whatever it deposites its eggs in and its larvæ feed on. The utility of entomological study and examination will be of paramount importance; for, doubtless, a careful inquiry into the habits, peculiarities, and destructiveness, of the various insects that are injurious to the crop, must lead, in many instances, to the discovery of an antidote for their ravages, or remedy for the injury they inflict.

There is evidently a great increase of insects injurious to agricultural production. What is the cause of this? The reason is the greater average mildness of winters, and the great destruction of small birds, snakes, toad frogs, water frogs, terrapins, and ants, which feed on insects. When the winter is very severe, the cold destroys myriads in their hibernating state of inaction, or temporary death. Again, it destroys the eggs, by bursting them, and thus making them unproductive. The

acute observer, by the aid of a microscope of only ordinary power, can, after any hard winter, see quantities of the eggs (generally adherent to small twigs) of the butterfly, ruptured and unprolific, from their generating power being destroyed by excessive cold.

But man has a greater friend than even these useful animals. *Insects feed on each other;* for some are predatory, and live on others, which are their natural food. Otherwise if this were not so, every vegetable growth on the surface of the earth, from the multitude of insects, would have long since been destroyed, and all animated beings must have ceased to live. If any doubt this, look at the many varieties of the spider; see the regularity, mathematical precision, and beauty of its web, woven with such art to entrap its destined food. Again the mud-dabbler, a species of wasp; preys on the spider itself, by storing them away in magazines of clay or mud, formed with considerable architectural skill, as food for their larvæ to feed on. Thus has infinite Providence in mercy and goodness placed checks which, apparently inoperative, inefficient, and imperceptible, still with unerring certainty retain within ordinary bounds the unlimited increase of any one species that, from their multitude, might become detrimental or destructive to all created beings.

The most important and useful among birds is the innocent little wren, intended by nature, from the number of its young, often twenty or twenty-five in number, its unceasing industry and perseverance, to be the general scavenger of the larva of the butterfly, on which they and their young feed. Their interminable industry, activity, and the multitude of the larva they destroy, are exemplified in the following experiment: I have attached to my country home a nest of these little birds, near to which stands a paper mulberry tree, from which, with watch in hand, I counted, in twenty-four minutes, forty-two of the larvæ of the butterfly conveyed to the nest by this pair of wrens. What, then, must be the amount destroyed in five weeks—the time it requires to rear their young brood—allowing twelve working hours to the day? It is immense, almost beyond calculation in its consequences. Supposing only one grub in a minute, it will make the destruction of the larvæ by this single pair amount in five weeks to 21,600. What, then, must be the number eaten by a few pairs of this truly useful and melodious little bird, which always seeks refuge near the habitation of man? How worse than cruel, then, their destruction by mischieveous boys or sportsmen, who, for lack of legitimate game, often wantonly destroy numbers of this and other species of little birds equally useful.

Unless coercive means be taken to prevent the destruction of such animals as feed on insects, the day is not far distant when failure of the most important agricultural products will arise from the depredations of insects; indeed many fruits and vegetables are now becoming scarce from this cause alone; witness the potato and pumpkin, not exceeded by the sweet potato in flavour and nutriment, and many other valuable vegetables unnecessary now to be mentioned.

The next most useful bird, from its great destruction of insects, is the bull-bat, or, as it is erroneously called, the whippor-will. Their nutriment is gnats of various species, some predatory and others injurious to vegetation; indeed all in the gnat form is grist that comes to their mill, even the tormenting and much dreaded mosquito. From the stomach of one of these birds I took and counted four thousand seven hundred and two gnats, consisting of nine different species—all the varieties I have noted. Besides, I am certain the stomach contained, partly digested, as many more, which from their partial dissolution, it was impossible to enumerate. Taking in view the rapidity of digestion in birds, what myriads must a few of this species destroy in the course of the summer!

The swallow comes next in the category. Observe its complete mechanical adaptation for swift motion. Has the vaunted power of man ever invented a projectile more perfect in shape to surmount the resistanee given by the air to all bodies rapidly moving through it? Observe how this perfect and beautiful little animal skims over river, lake, or plain, apparently in sport, but actually destroying multitudes of insects for food, among others the fabled gallinipper and well known mosquito.

The water-martin is useful by destroying many species of a larger size than the preceding. Again, there are the tom-tit and sap-sucker, heretofore considered to be injurious by the holes they make in the apple-tree: from the erroneous supposition of injury to the tree by making these incisions, numbers have been slaughtered. How fatal a mistake! Notice when the tree is completely bored all over the body, and some of the chief limbs, how thrifty it looks; how large and sound the apple; and how luscious the flavour of the fruit. Observe the trees which have not been visited by these birds—many look skin-bound, fruit small and knotty, taste flat and watery.

What is the rationale of this? Simply that each perforation is made for the extraction of the larvæ of an insect, which, if not removed, would spoil the size and flavour of the fruit, and eventually destroy the tree. What a pity, then, to exterminate so useful an animal! Man often from impulse, without proper consideration, immolates his best friend. Contrary to common belief, I consider the famed locust beneficial to fruit trees, notwithstanding the great outcry about their destructiveness—a fact very easily substantiated if germane to the present matter.

So the more we learn of the intricate minutiæ of creation, the greater our surprise and admiration of the wonderfully wise system of check and counter-check established, where we see animals almost imperceptible, and apparently the most useless and contemptible, performing functions which, to the superficial, would seem incidental and objectless; but the deep observer of nature, scanning everything with a philosophic eye, sees and recognizes in the action of the most insignificant *a necessary link of the chain,* without which the beauty and grandeur of the whole would be marred; rendering it a doubtful problem if creation itself could exist without their agency.—*Diary of a Country Doctor.*

PRESERVATION OF GRAIN FOR FOOD.

In the number of this magazine for October, 1856, and in following numbers, we presented a few remarks on the important subject of drying of grain in the bulk. We now propose to glance at those projects which have for their aim the preservation of the grain after separation from the straw. Our remarks in connection with this subject will be confined chiefly to wheat, that being the most important of the cereals with relation to the food of man, as yielding the largest per-centage of flour in grinding, the loss being only one-fourteenth, while that of oats approaches nearly to one-half, barley coming closer to the standard of wheat, giving nearly six-sevenths of its weight in flour.

That which chiefly influences the preservative power of wheat is the amount of water or moisture it contains. Containing from 12, 14, 16, and in some cases 20 per cent. of moisture, it is in this condition liable to decomposition; and it is only when the per-centage of moisture is reduced to 8 and 10 per cent. that its keeping in good condition can be secured. In certain parts of the continent, where this moisture is greatly reduced in wheat by careful ventilation and drying, it can be kept without injury for lengthened periods, varying from seven to fifty years. But not only is the preservative power of wheat increased by careful drying: it greatly augments the value of the flour obtained from it for bread-making purposes. "It will yield," says a practical miller, "much more flour per bushel, and require about half the machinery to manufacture it, than it otherwise does if not dried. The quality of the flour is improved at least 10 per cent., as by drying the wheat all impurities of a vegetable nature are entirely removed; and by extracting its natural moisture, the flour will consume, when baked, more water than it would before the grain was dried, which makes the bread much more palatable, it being more spongy." The higher, then, the per-centage of moisture in grain, the more difficult is it to keep, and the less valuable is the flour obtained from it. In a warm climate—as that of the United States—in summer, the addition of moisture to grain or flour has a tendency to diminish the quantity of gluten, and to promote such a change in the constitution of its parts as to prevent good baking, or "pannification," as it is termed. An excess of moisture also favours the production of sporules of different kinds of mushrooms, these being developed in the bread which is made from the flour so deteriorated. Professor Dumas states that the wheat of the year 1841, remarkable for its warm summer, exhibited in a high degree this defect. The bread in which these mushrooms were developed was raised in temperature, and soon presented a mass of reddish and disgusting matter. By thoroughly washing the infected grain, and following it promptly by a desiccation or drying, the number of sporules was much diminished. The development of the mushrooms in the bread was, in some measure, prevented by reducing the proportion of water, increasing the quantity of salt, and by increasing the temperature of the oven in which the bread was baked. Seeing, then, the chances of loss and deterioration of value which surround the farmer in the storing of his grain, it is obviously a matter of no mean importance to investigate those plans which have been proposed to preserve it in a condition fitted to produce the largest amount of good bread-producing flour.

The preservation of grain for food-purposes obviously resolves itself into two processes: first, that which gives the grain those qualities which retard or prevent decay; and second, that which tends to preserve or maintain those qualities. The two processes we therefore call the "preparative" and the "preservative."

The main feature of the "preparative" process is the getting rid of the excess of moisture. This drying, or desiccation, as it is termed, may be effected in a vast variety of ways. Perhaps the oldest of all the plans requiring special arrangements—other than those involved in the most ancient of all modes, spreading the grain in the sun-heat—is that introduced by Dr. Stephen Hales in 1743, and held in high repute, according to cotemporary evidence, by the farmers of the time—a curious instance, by the way, of the odd fate which meets many inventions and processes, used to-day and obsolete to-morrow; and that not from better being introduced to supersede them, but from the process which they are designed to aid being quite ignored in succeeding practice. The method adopted by Dr. Stephen Hales was blowing or forcing currents of air through the mass of grain exposed to its influence. A tube perforated with holes was inserted in the centre of the mass, into which the air was blown, pouring through the apertures and permeating the material. The farmers of the day used a modification of this plan by taking a reed or cane perforated with numerous holes throughout its length, placing it in the centre of the grain retained in a sack, and blowing, by means of a common bellows, quantities of atmospheric air through it. In the "Gentleman's Magazine," a statement is given which shows that the plan was in use in France. A member of the Academy of Sciences, M. Hamel de Monceau, having preserved a large heap of corn free from weevils for two years without turning, by merely blowing air through it. If we preserve the blowing feature, and substitute hot air for that having the ordinary atmospheric temperature, we increase the desiccating or drying properties, and arrive at a process of recent invention, which assuredly takes its place as one of the most efficient, if not the most efficient, of all plans for preserving vegetable substances. We allude to the desiccating process patented by Messrs. Robert Davison and William Symington, of London. This plan may be briefly described. A series of cast-iron pipes are arched over a furnace, through which, by a powerful fan, a current of air is forced. The high temperature of the pipes heats the air. The mate-

rial to be dried is placed in a chamber, into which the heated air is forced, passing off, after permeating through the mass, by a ventilation at the top of the chamber. By simple means, the temperature of the air issuing from the pipes over the furnace can be regulated to a great nicety, from a heat capable of melting lead, to that of the summer's softest gale. The drying power of the apparatus will be best proved by the statement of a fact or two gathered from the experience of those who have used it for wood-drying purposes. "A saw-maker, of well-known reputation in London, sent to be seasoned a piece of rich beech, of which saw-handles are made, and which he would vouch for having been in his possession for twelve years, and during four years of the twelve, it had been lying on the tie-beams of a roof immediately over a smith's forge. From its appearance and sound, this wood would have been pronounced thoroughly dry; yet, after being exposed to a current of heated air at a temperature of 240 degrees, for about two days, it lost 11 per cent. of its weight." A violin, which had been in the possession of a party for sixteen years, its age previous to its coming into his possession not being known, lost on being subjected to the process, in the course of eight hours, as much as $5\frac{2}{3}$ per cent. nearly of its weight. These facts we give as illustrative of the drying powers of currents of heated air.

There can be no doubt that great benefits would arise from some simple apparatus by which currents of heated air could be quickly and economically obtained, to be applied to the drying of grain, either while in conjunction with the straw, or after being separated from it. The chamber for heating the air would be a matter of easy attainment. In nearly all improved farm-buildings, a steam-boiler or steaming apparatus is met with; this will provide the heating-medium. A chamber or steam-chest should then be provided, in which and through which externally, from end to end, or side to side, a series of pipes should be inserted. The steam, being admitted to this chamber, envelopes the peripheries of these pipes, raising their temperature, and that of any air which may be contained in or passed through their interior. Let the openings of all the pipes on one side of the chamber be covered with a hood or external casing, which hood should converge to a single pipe of area nearly equal to the combined area of apertures of pipes passing through the chamber. The same should be done at the other side of the chamber. One of the hood pipes will be that through which the fanners project the air to pass through the pipes: the other will be that which will lead the heated air as it passes from the pipes to the chamber or receptacle in which the grain is placed which is to be subjected to the drying process. In place of steam, air heated in a furnace or by contact with hot surfaces may be used as the drying medium. And instead of pipes, a series of flat chambers placed in zig-zag fashion may be constructed above a furnace or alongside of the steam-engine boiler furnace, and through which air may be blown by a fan, and passed at once into the drying chamber. Further, in addition to the drying of grain detached from the straw by the method here detailed, it is obvious that the plan is applicable to the drying or keeping dry of the grain in the sheaf as stored up in the ordinary stacks; for it is only the addition of a tube well perforated with holes running up the centre of the stack, and through which the heated air can be forced, that is required to make the plan available.

But to return to the drying of grain as detached from the straw: it is clear that the method described, of forcing currents of heated air through *lying masses* of grain, will be most quickly carried out where the bulk of the mass is reduced to a minimum. The economy of the process will be in proportion to the rapidity with which all parts of the mass, and all parts of the individual grains constituting the mass, can be subjected to the action of the currents of heated air. This leads us to the philosophy of the process of drying grain in masses.

If we direct our attention to the simplest of practised methods for drying grain by artificial heat, namely, the kiln, we find that the grain placed *en masse* on the perforated tiles, which form the floor of the chamber, is under circumstances most disadvantageous to its rapid thorough and uniform drying. Placed in a thick layer on the tiles, the moisture evolved from the lower strata has to ascend through, and pass in contact with the strata above; the particles constituting these upper strata necessarily imbibe the moisture thus coming in contact with them; and this before it can be expelled has to be subjected to a temperature which may be too high for the lower strata on which it rests. If, therefore, the heat of the kiln is regulated so as best to dry the stratum or strata immediately subjected to it, that is which lie on the perforated plates, it will be too low to effect as quickly and surely as desirable the upper strata which are in the receipt of the ascending moisture of the lower; or on the contrary, if the heat supplied is of a temperature sufficient to dry the upper strata, it will be too high for the lower. We may thus find in practice different strata of grain under widely different circumstances of drying, thus precluding all chance of attainment of *uniform* drying. True that in practice this uniformity is attempted to be attained by repeated shovelling and turning over of the grain as it lies on the tiles. We say attempted to be attained; for the inherent clumsiness of the process precludes all possibility of perfect adjustment of the so-prepared grain to the peculiar temperature which secures the right degree of drying. From this slight investigation of the circumstances under which kiln-drying is performed, we may deduce as a rule or standard of correct drying the following: "That every individual grain shall have each portion of its surface subjected to the drying influence, and the process so under control that it can be regulated to give the merest shade of surface drying, up to and through all the gradations of scorching and burning." This standard or rule involves two necessities of operation: first, that the temperature shall be easily regulated; and second, that means shall be provided, by which each grain shall have its due share of the heating medium. The reader anxious to have a *resumé* of the plans by which

these have been proposed to be attained, may consult an article entitled "A few Notes on Corn drying, and its Advantages to the Practical Agriculturist;" contributed by us to the *Journal of Agriculture*, No. 44, new series. We shall here confine ourselves to the description of one which we consider very efficient as a mechanical means of laying all the grain in contact with the heating surfaces, turning it over and over continuously during the whole of the period in which it is passing through the machine. The invention is founded upon the well-known Archimedean screw, which is frequently used to convey flour from one part of a mill to another. If our reader has witnessed the action of this apparatus, he will have noticed, doubtless, that while the flour is gradually led or moved along from one end of the trough to the other, there is no displacement of its particles from one *side* of the trough to the other; that is, the flour is moved along in one mass, without any disturbance of its material particles. If the reader, however, will imagine a series of plates or ribs, to be placed between the threads of the screw, passing from one to another parallel to the axis, he will easily perceive that as the screw revolved, and each rib came in contact with the flour, it would dig into it, pass it from one side of the trough to the other, and partially lift it up past the centre. Suppose a series of tubes or pipes to be placed in a heating chamber, and each containing an Archimedean screw revolving slowly, and provided with the ribs as above described, one tube communicating with the other by means of shoots or conductors; if the grain to be dried was passed into the upper tube, as it moved along the ribs between the threads it would keep continually lifting it up and dropping it, until it was delivered to the further end of the tube, from which it would drop through a shoot to a second tube, in which it would be subjected to another series of liftings and droppings, till it was delivered to a third tube, and so through a series of seven tubes. It is obvious that every portion of each individual grain would be subjected, not once only, but repeatedly to the action of the heated surface of the tubes through which it passed. In this machine, the invention of Messrs. Robert Davison and James Scott Horrocks, the two necessities involved by the standard or rule of drying already given are met. The regulation of the temperature, or what amounts to the same thing, the degree of drying, is attained by adjusting the number of the tubes through the grain is to pass, and the rate of revolution of the screws which work in them; for the greater the number of the tubes, the more heating surface there will obviously be; and the slower the number of the revolutions of the screws, the less frequently will the grain be lifted up out of contact with the heated surfaces, and the greater therefore will be the amount of drying which they will receive. The second requisite is also met by the means adopted of giving movement to every individual grain as it passes through the tubes. This movement, or lifting up, can be modified in degree, by increasing or decreasing the number of the ribs placed between the threads of the screws.

Having shown how the first, the "preparative" process involved in the "preservation of grain for food purposes" is effected, we now turn to that by which the second or "preservative" is carried out; that is, after having dried our grain, let us see how we are to keep it dry.

The most obvious method to insure our grain being kept dry, after having once made it so, is to store it up in thoroughly dry and vermin-proof granaries; but it is not so obvious that in few cases indeed are granaries, however well built, capable of giving either the dryness or freedom from vermin which the necessities of the case desiderate. To insure these requisites great expense in construction will be necessary, and it is doubtful whether the most complete constructive arrangements can give the freedom from atmospheric agencies of a hurtful kind which is requisite. In the preserved meat tin, in the lead-lined tea-chest of the Chinese, in the housewife's canister, in which is stored up her valuable commodities, in the corn-bin of the stable, moreover, we have an example of what a good wheat-store should be. True, with our preconceived notions of granaries, it is difficult to look upon any plan, in which this principle is carried out, with any other feeling than that of surprise or ridicule. But a very slight consideration will suffice to show that there is nothing difficult of attainment in making air-tight canisters to store wheat up in. On this very subject Mr Bridges Adams—to whose facile pen the scientific world owes many suggestive hints and useful plans—some years ago wrote a paper to show the feasibility of storing up grain in the manner we have hinted at. He says—"There can be no doubt that, if we were to put dry wheat in a hermetically sealed tinned case, it might be kept as long as the famed 'mummy wheat' of Egypt. This will be readily admitted, but the expense would be queried. Let us examine into this. A canister is a metallic reservoir; so is a gasometer, so is an iron water-tank in a ship, at a railway-station, or elsewhere; and a cubic foot of water-tank on a large scale will be found to cost very much less than a cubic foot of canister on a small scale. And if a bushel of wheat be more valuable than a bushel of water, it will clearly pay to put wheat in large canisters of iron. The wheat canister, in short, should be a wrought-iron or cast-metal tank of greater or less size, according to the wants of the owner, whether for the farmer's crop or for the grain-merchant's stock. * * The size of the reservoir should be proportioned to the locality, and it should hold a specified number of quarters, so as to serve as a measure of quantity, and prevent the expense of meterage. * * Granaries of this description would not occupy more than one-third the cubic space of those of the ordinary description, and the cost would be less than one-fifth." Such are some of the advantages of this method of storing up grain, as stated by Mr. Adams. About the same period at which Mr. Adams promulgated this plan, a patent was taken out by Peter Armand le Comte de Fontaine Mereau, in which was claimed a method of storing grain similar in principle. "The invention," as stated in the specification, "consists in the use of closed metallic chambers, serving as tubular granaries or receptacles for

the seed, rendered impervious to moisture and atmospheric influence by a covering at top, hermetically closed, affording thereby the means of frequently ascertaining the degree of humidity within. The corn or seed, having an excess of moisture is previously desiccated. These tubular granaries—which may be laid under-ground, or partially or wholly above—consist of a metallic case, preferably constructed of sheet-iron, covered outside with a coat of hydraulic or other cement, and, if necessary, with a coat of preservative varnish. * * The chambers are closed with an iron lid or plug, with a pad of leather, caoutchouc, or gutta-percha introduced between the parts in contact, and by an inner cover adapted to the neck of the chamber, hermetically sealed." A claim is made for the adaptation of examining tubes connected with the lids, and dipping into the interior of the store vessel. Sounding tubes can be inserted into these tubes, so as to bring up and ascertain the condition of the grain at any desired depth.

As applicable to this method of storing grain in separate vessels, and also to the preservation of flour in receptacles, we here notice a method of preventing and retarding decay in accumulated masses of food, which depends, according to the patentee, on very simple principles. "This invention is based upon the theory that in vegetable substances which contain only a small quantity of moisture the process of decay always, or almost invariably the commences at the centre of the mass, and from thence extends in all directions. It is well known to millers and others engaged in the manufacture, storage, and transportation of flour, meal, and grain, that in these substances such is the case, the centre being frequently found soured and heated highly, while those portions near the outside of the mass are uninjured. It is also the case in hay or other substances of a similar nature. In order, therefore, to retard as much as possible the process, the nature of this invention consists in removing the centre of the mass, by placing therein an open tube or tubes, or by the employment of similar means, by which the mass is so distributed that, if decay commences at any point, it must extend to a very great distance in order to affect any considerable portion of the mass, and therefore its progress must be very slow. By thus removing the centre, the mass is also distributed in a body of less than one-half the thickness it would otherwise be; and thus it is believed that the tendency to decay is in a great degree prevented." The name of the patentee is Edward Loradoux Bellford; the date of the patent May 12, 1854.

The principle, if correct, is of easy adoption in practice; it is applicable obviously to corn-bins and corn, or hay-stacks also. In these latter all the advantages of the tubes may be obtained, as suggested by the patentee, by placing a series of poles in the centre, so as to form a tube or ventiduct. There can be little doubt of the efficacy of the plan of a central tube, where air, warmed or otherwise, is forced through it by fanners, as already suggested.

Should any of the methods above described be considered too much out of the range of ordinary practice, and granaries after the methods of our fathers deemed the best, it will certainly be worthy of all consideration whether—in view of the on-all-sides acknowledged benefits derivable from passing currents of air through masses of grain—it will not be, to say the least, a common-sense-like method of proceeding to make some simple arrangements by which currents of air could be brought in contact with grain as it lies on the granary floor. This could, at comparatively small expense, be effected by making the floor double, the upper part of perforated plates or tiles; or, what would be cheaper, constructing a series of channels, at greater or less distances, between the line of joists, with openings tending upwards to the granary, and into this double floor or through these channels, sending currents of air by artificial or natural means. The air passing through the aperture would permeate the mass of superposed grain, and be discharged through the ventilators at the top. In home-stalls or steadings, where stationary engines and fixed thrashing machines are used, the granary being in close contiguity with the apartments in which these apparatus are placed, every facility is fortunately given by which power can be adapted to the forcing of the currents of air through the channels we have described.

With the scientific and practical evidence surrounding us in favour of the value of dried grain for bread-producing purposes, and of its preservative powers, and with a wide choice of plans by which this drying or desiccation can be easily, economically, and perfectly ensured, small excuse can be made for the farmer who complains of having grain, the deterioration of which in value and preservative influences arises from an excess of moisture—the cause, be it here noted, in nine cases out of ten, of the decay of grain. With the aid which the steam-engine—an appliance of nearly every well-conducted farm—gives the agriculturist, a very slight exercise of inventive ingenuity and constructive skill on his part will enable him to improvise some simple mechanism by which he can realize, in some measure, the effect of the summer's heat with the winds of early spring—a combination for the preservation of vegetable substances than which nothing can surpass. R. S. B.

PREMIUMS FOR THE BEST SAMPLES OF BARLEY.—Last year Messrs. Blizards and Godsall offered a prize of a silver cup, of ten guineas' value, to the farmer who should sell them the best sample of Barley, not less than two hundred bushels in quantity. The competition was sharp and close, and the results were so satisfactory, that the firm immediately advanced upon their first attempt, and for the succeeding year offered two cups, upon the same conditions, one to be competed for by growers in the counties of Gloucester, Worcester, and Hereford; and the other by those of Oxford, Wilts, and Berks. The cups were adjudged on Wednesday last, and about fifty samples were shown from the first-named counties, and ten from the other three. The judges, Messrs. Ashby Saunders, brewer, of Cheltenham; W. Turk, maltster, Cheltenham; and W. H. Gillett, corn-merchant, of Swindon, decided that one prize was due to J. Hall, Esq., of Ripple, Worcestershire; and the other to W. T. Hayward, Esq., of Little Whittenham, Berks; and they highly commended the barley shown by Mr. Lane, of Ripple, who won the cup last year. The various competing samples were ranged on Messrs. Blizards' stall in the Corn Exchange, and formed a very great attraction during the hours of business. The event was celebrated by a dinner at the Swan Hotel, which was attended by a great number of the agriculturists and merchants of the neighbourhood, as well as many from a distance.

THE ROYAL AGRICULTURAL SOCIETY.—PROCEEDINGS IN COUNCIL.

The recent proceedings of the Royal Agricultural Society have been of more than usual interest. In addition to the general business of this period—where shall we go? and what shall we do?—there have been two or three special questions to consider. Amongst other matters, the Council have proposed to find becoming successors to such men as Mr. Pusey and Professor Way. They have publicly announced that the Society required a new Editor and a new Chemist.

To only a certain extent have these wants been supplied. The new Editor, in short, is not forthcoming; and the Directorship is still to remain with the Triumvirate. If these gentlemen can devote the time they have hitherto given to the work, we see no reason why they should not continue to conduct it. The late proposition, indeed, by no means ignored their claims or abilities. We take it to be no secret that this was but another reading of the Sibyl's volumes. Instead of the three editors, the charge was to have been confided to one of them, with such assistance as he might require, and at a salary of five hundred a-year. After the question had been twice adjourned, the General Council have refused to sanction this recommendation of their Journal Committee. They have, however, left three hundred per annum at the disposal of the same editorial staff. Tested by the position, tastes, and habits of Mr. Pusey, it may be some time before the one right man turns up.

The solution of their other difficulty has been apparently more readily arrived at. With high recommendations and long experience, Professor Voelcker now reigns in place of Professor Way; and has already read himself into office. It was only, perhaps, when hearing the opening lecture of his successor, that the Society could have felt the peculiar loss of such a man as Mr. Way. As a teacher by word of mouth—stripping science of its technicalities and pedantry—there are few, indeed, equal to him. We never listened to any one more easy to follow, or that so clearly impressed upon his audience those points they should remember. Professor Voelcker, in short, followed close on a well-graced actor, and the comparison was involuntary. We should be the last to damp the spirit of the new comer, but it must be confessed that as a lecturer he has something to learn. It could scarcely be supposed that he has had the experience in this way we know him to have enjoyed in the West of England. As a writer on the chemistry of the farm Professor Voelcker is clear, plain, and forcible; while his brother-chemists all testify to his great professional attainments. As a speaker, on the other hand, he is often rambling and illogical. The first half-hour of his inaugural address on the old hackney common-places of Science and Practice, was unquestionably a mistake. One almost tired of waiting for what he was coming to. While warmly welcoming their present officer, the Society have given their old ally but a cold good-bye. We think, though, this want of expression is more with the Council than the general body of Members. Professor Way was, and deservedly, a very popular man with the farmers; and he will be so still.

There has been plenty of work to do, beyond even the consideration of these important appointments, and many the references to the sub or working committees. The Implement committee has, more particularly, been called upon. First of all, they have to reply to a memorial from the exhibitors of steam cultivators who ascended the heights at Salisbury. The point of this petition, which is being fully canvassed in our columns, is, that the steam plough should have a little more fair play at Chester; and this the Implement committee is to look to. It is really gratifying to see with how much good feeling the different inventors of steam ploughs are working on to the one great end. Mr. Fowler and Mr. Williams are about to unite their forces; while Mr. Fowler, in a letter addressed to us only this week, bears witness to the results arrived at by Mr. Smith of Woolstone:—"Mr. Smith has kindly consented to show his farm as a practical proof of the value of steam cultivation; and I intend to station a suitable person in the neighbourhood, to wait on those wishing to see it." Or you may have the effect of such a system on the farms of Mr. Mechi, Mr. Hobbs, or Mr. Killin; and this very week Mr. Williams is to begin on a forty-acre piece in the occupation of Mr. Owen, the chairman of the London Farmers' Club. In good truth, the steam plough is again looking up—one of the most encouraging proofs of its progress being the spirit evinced by its several supporters rather to aid than to retard each other.

Then, there have been numerous suggestions as to the trials of the steam-engines—the "Blue Ribbon" honour of the agricultural year—with already a manifest anxiety as to "who is to win?" and every district with its own favourite. And further, the President has called the attention of the Council to the completion, this year, of the triennial arrangement for the trial of implements at the Country Meetings of the Society, and to a consideration of the propriety of its renewal or continuance for the future. Acting on this hint, a committee, consisting of the members of the Implement Committee, and of Mr. Howard, Mr. Shuttleworth, Mr. Caldwell, Mr. Huskinson, and Mr. Amos, is appointed, with power to confer with a deputation from the body of the implement makers, and to report to the Council at their next monthly meeting in June. It may be asked who are responsible for all the good or evil doings of this Implement Committee, and we give, accordingly, the elements of its construction:—Chairman, Colonel Challoner; Lord Portman, the Speaker, the Hon. W. G.

Cavendish, Sir A. Macdonald, Sir J. V. Shelley, and Messrs. Brandreth, Brandreth Gibbs, Hamond, Hobbs, Hoskyns, W. Miles, M.P., and H. S. Thompson.

What will the exhibitors have to say in answer to this invitation? Has the triennial plan worked well or not? We incline to think even better than could have been expected. The question then is—Shall we continue it?—Return to the old system?—Or, have no prizes and no trials at all? The answer would seem to be self-evident; although the small end of the wedge may have been introduced.

Sorely to the disappointment of Oxford, the Country Meeting for 1859 is to be held at Warwick—a very good selection. The Society has no need as yet to run upon a beaten track. There is plenty of fresh ground still to be broken up. In addition to its convenience of situation, Warwick has other attractions to recommend it. The frequenter of these meetings must in time see all the best of his own country, quite as a matter of business. There was the run over from Carlisle to Windermere; the drive from Salisbury to Stonehenge; the lions of Oxford and Cambridge. And there will be Kenilworth, Stratford, and Guy's famous castle, in pleasant association, but as agreeable variety with sleek Shorthorns and iron ploughs.

One word more as to these recent proceedings, and that one to the important matter of Finance. A member who has not paid his subscription must not expect to receive his copy of the *Journal*. And how would a man get on without the *Journal*? With such a threat in terrorem, Mr. Hudson's time for the next fortnight should be chiefly given to the signing of post-office orders.

THE NEW MANURE—CLAY FROM THE GAS-WORKS.

We congratulate the agricultural world on the improved tone pervading the teachings of its scientific instructors. Theories are enunciated cautiously, and modestly guarded with allowances and provisoes; and research in the laboratory is duly acknowledged as elucidating rather than dictating practical husbandry. Take, for instance, some most valuable papers in the last "Part" of the R. A. S. E. Journal.

The Rev. Mr. Bowditch has discovered a new source of manure—namely, in the purification of coal-gas by means of clay, which absorbs the ammonia hitherto unarrested by the ordinary process. Carbonate and sulphate of ammonia thus acquired by the aluminous soil used, are doubtless good fertilizers; but what will be the effect of the sulphocyanide of ammonium and other metals which it also retains in considerable quantities? Well; "sulphocyanic acid is found in the saliva of man and the sheep, and must either be taken in the food as such, or produced in the body by the vital processes. Mustardseed, again, is known to contain the sulpho-cyanide of allyle. Horseradish and Alliaria officinalis contain the same substance. The garlic and common onion contain an oil which differs but little from that of mustard, &c. With these examples of analogous compounds in the animal body and in vegetables, there seemed little risk in applying sulpho-cyanides in quantity." Again: "Many compounds of cyanogen, produced by the distillation of coal and retained by the clay, found corresponding ones in the urea and uric acid of urine and guano; the hydrocyanic acid of bitter almonds, peach kernels, the leaves of the cherry laurel, &c., when distilled, and other compounds of both kingdoms of Nature, which it is beside our object to discuss." Now, what we have to praise is, that instead of directly seizing the conclusion that the doubtful substance must be a fertilizer because it is found in the animal and vegetable organism, this chemist is content to take these facts as simply *warranting the risk* of a practical trial, and tests *in the field* whether or not the ingredient he believes to exist in onions will injure or improve them when applied as a manure. Accordingly he tries the clay, and greatly augments his crop. "At present," he says, "any attempt at producing analyses to account for visible effects, and saying thus and thus these substances act—hence, and not elsewhere or otherwise the fertilizing power is obtained—would be, in my opinion, unpardonable presumption. The analyses must be explained by the phenomena: the phenomena must not be tortured to fit the analyses. *I have hitherto withheld the results of much labour* on this ground, and propose to learn from, and not to impose interpretations upon, Nature. Chemistry is honoured by becoming Nature's handmaid: it is made contemptible when put forward as her guide."

One of the most successful experiments with the new manure—"clay from the gas-works"—was its application to turnips. "This was the very application which theory would indicate. Here was the most sulphurized of all manures being applied to the most highly sulphurized of our field crops. The question put was, 'Will excess of sulphur in manure promote excess of growth in turnips?'.... The crop was inspected by many, who all agreed that they had never seen it surpassed." Yet this was on a piece of poor soil in a garden. Of course, the usual explanation is ready enough: "The ammoniacal salts and other compounds of nitrogen promoted this luxuriant growth of turnips—the sulphur played but a subordinate part;" and chemists, unfortunately, lend their authority to this opinion, asserting that soils always contain an abundance of sulphates, and therefore farmers need not trouble themselves to add sulphur. "But is this so? May not the superior action of dissolved bones, superphosphate, and similar compounds, be due in a great measure to the *sulphuric acid* they contain, and not simply to soluble phosphate which does not exist in the soil, or insoluble phosphate 'in a fine state of divi-

sion?' I confess myself strongly of the opinion," says Mr. Bowditch, "that the sulphuric acid is a very potent agent in bringing about the good results which are so familiar, from compounds in which it is used; and when we recollect the raising of a crop of turnips by watering the drills with dilute sulphuric acid only, and the other successful experiments collected by Johnston ("Experimental Agriculture," p. 104-5.), I cannot help attributing the success with turnips, above described, as much to the sulphur compounds as to the compounds of nitrogen. Does not the known efficacy of woollen rags as a manure point in the same direction? I know, of course, how large a proportion of nitrogen they contain, and how this is usually dwelt upon; but is it considered that they contain an amount of sulphur which is capable of forming 12½ per cent. of their weight of anhydrous sulphuric acid, and that the hop, for which they are almost a specific, contains a sulphurized oil nearly, if not altogether, similar to the oils of mustard, garlic, onions, &c.?" There is independence of view in these remarks, a breaking away from the beaten track of Liebig and Lawes, and the customary authorities, and an opening up of fresh ground for thought on the subject of plant-food—that we both admire and approve. The following shrewd observation indicates one cause of our long subservience to nitrogen as the royal manure: "When nitrogen compounds can be purchased more cheaply than at present, other ingredients of manure may perhaps receive closer attention than they now obtain. The extreme importance, and increasing price of nitrogen, has pushed it somewhat beyond its true position."

Passing by the proposal of the new manure for grass lands—in which we are reminded that "all the nitrogen of wool and hair came originally from the soil, and most of it from grass;" that "the five millions of pounds of sulphur on the sheep's backs of this country were principally derived from grass," and thus the continuous removal of minerals without return must tend to deteriorate the land—we take another instance of our author's moderation in the presence of startling and very winning results from his experiments with the new manure upon potatoes. "The 'potato-disease' has an interest for everyone, whether he be a producer or consumer; and as an experiment of last year bears upon the subject, it should be known." Of 3 acres of Prince Regent potatoes, 2½ acres dressed with the gas-clay were free from disease, and on the remaining half acre the principal portion of the crop was affected; the disease appearing badly in all the district, namely, Wakefield. Whereupon we have these observations: "I was prepared for the better crop which accompanied the special manure, but its influence over disease was entirely unexpected. I think also it is unexplained. *If* the disease be owing to the attack of a fungus, and *if* sulphur in some or all of its combinations be a preventive, and *if* carbonic acid and arsenic (both of which exist in small quantity in the clay) prevent its attack or its growth, we may account for the prevention in this particular case; but where the whole subject is so entirely beyond the limits of our present knowledge, it appears more becoming to hesitate in the expression of opinion. What is certain is, that the attack of disease, and of course the presence of a fungus, could be traced down the stems below the earth to the tubers, *where it stopped when these were in contact with the gas-manure*, and to which it extended in all other cases. But an isolated instance does not prove that we have here a specific against disease, nor even that the action of the same agent will be the same on other soils and under other circumstances. Trials alone can do this, and trials in sufficient number to warrant an induction."

A great discovery seems here to be close at hand; and yet it is the part of wisdom to restrain the first impulse to hail with rejoicing the apparent new truth, and wait with patience for the tardy proof or too speedy disappointment.

THE MEMORIAL FROM THE EXHIBITORS OF STEAM CULTIVATORS.

We proceed with the memorial which Mr. Collinson Hall, Mr. John Fowler, junr., Mr. Charles Burrell, and Mr. John A. Williams have addressed to the Council of the Royal Agricultural Society:

"We, the undersigned exhibitors of steam-ploughs at Salisbury, are of opinion that the trial of those machines at that meeting was of an unsatisfactory character, and not such as was calculated to develope their merits, but rather, by putting them into exceptional circumstances, to injure them in the eyes of the public, and was not consistent with the importance of the subject, or a fair return for the large outlay incurred by us in exhibiting them there." Here we pause to express, not our approval of the construction of this sentence, but our hearty assent to its statements. Everybody who saw the ground will testify that the trial was a mockery, and that it was a hard case for the inventors, after their immense pains and pecuniary sacrifices, to be placed before the assembled agricultural world in a position where their powers could not possibly be displayed.

"As the third offer of the Society's premium has again brought the subject under our notice, and as we cannot but think that *the withdrawal of those schemes at present most prominently before the public from competition* would be prejudicial to the progress of the invention, and would greatly detract from the interest of the Society's meeting at Chester, we would respectfully request that the Council would consider whether such terms and conditions of trial could be arranged, and published previous to the day of entry, as would enable those intending to exhibit to judge of *the advisability of their incurring the heavy expenses necessary to such a competition.*"

Though the members of these sentences do play a little at "cross-purposes," still, in spite of the composition, it is clearly to be understood that the exhibitors are not again anxious to purchase "a pig in a poke;" and, as we shall see, they have good reason for requiring precise explanation of what awaits them at Chester.

"As we observe that the judges in their report of the trial at Salisbury express the opinion, 'that the wording of the premium can never justify a judge in giving a prize whilst a *plough* is used,' it is we think essential that it should be clearly stated *whether any or all those plans which we represent are excluded* by the wording of the offer of the premium from competition."

Now, five of the judges understand by the words of the Society's offer, "an economical *substitute for the plough*," a machine that shall "turn-over" the soil in a different manner to that of the plough. No modified form of plough, having share and mouldboard, and turning over a furrow-slice by a screw-wedge action, can receive a prize at their hands. They must have a new variety of tilling implement. But two of the judges understand the terms to mean, a substitute for the common or *horse* plough. That is, a steam machine which can economically take the place of the present horse plough, no matter whether effecting precisely the same or a better tillage operation. They want either ploughing, or some other process equally effective, done by steam-power instead of horses. The thing you "substitute" for another is not necessarily of *a different kind;* but it may be either of the same or of a different kind, provided only that it "stand in place of" or answer the purpose of the other. It might be argued, indeed, that a "substitute for a plough" *must perform the work called ploughing;* otherwise, it would not take the place of the old implement; and not being able to accomplish the same end, could not be called a "substitute." But why quarrel about words? Mr. Wren Hoskyns says, "When it is already evident that a plough worked by steam-power gets rid of *some* of the evils incidental, on certain soils, to that worked by horses, it becomes quite conceivable that *retaining substantially the same form*, it might yet come to get rid of those remaining. The nominal objection could hardly survive the real one, since the only object of substitution is the complete removal in the substitute of the defects in the original. This accomplished, substitution is literally as well as substantially attained, for *there is nothing in the etymology of the word to prohibit similarity of form in the instrument* which shall furnish the whole of the qualities required . . . .; while it is equally true that there is nothing in the nature of the prize which prohibits a suspension of judgment, while this object may be in process of accomplishment." Let the Council state plainly whether they understand their own offer in this sense—whether they will award the premium to the steam machine that is found the most "economical substitute for the plough or the spade," no matter whether coulters, shares, and mouldboards be parts of it or not, so long as it fulfils the object in view. This is, the tillage of land by steam-power as effectively and more advantageously than by horses.

"We would also suggest that to insure such a trial of these machines as the importance of the subject deserves, a much longer time is necessary than can be given during the show week by the judges, who have a great many other duties to attend to; and that it would be of great importance that the judges of this department should have their whole time at their disposal for this subject, as no fair comparison with horse labour can be instituted except by a lengthened trial." We hope that this request will be complied with; and that the steam-cultivator may not be left for the cursory inspection of the judges, after examination and trial of the thrashing machines, chaff-cutters, and mills. Let us have a trial of several days' duration, with coal weighed, time taken, and work measured; and in a situation favourably adapted to this young class of invention, rather than selected and laid out so as to baffle the inventors with unfair and unusual obstacles. Let us not absurdly test general efficiency by means of a maximum of difficulty. "The length of time that elapses between the publication of the judges' report and the adjudication of the prize also exercises a very prejudicial effect on the business to be done at the meeting. So much so that, in our opinion, a machine known not to be competing for the premium stands a better chance of obtaining orders on its own merits than one upon which a report is expected in a few months, and for which the public are likely to wait." There can be no reason why the judges of the steam cultivators should not give in their report while on the spot; though it is perhaps too much to expect the necessarily elaborate reports upon all the numerous classes of machinery and multitudinous "miscellaneous articles" in the show-yard. Let the judges of steam cultivators, reapers, thrashing machines, and steam-engines at any rate, if not of other important machines, have time to conduct the necessary experiments, and afterwards compose their separate reports, before or during the public show-days. And for this purpose the work should be more divided than heretofore, rather than more classes forced upon fewer judges.

THE TRIALS OF THE THRASHING-MACHINES.

SIR,—The inclosed paper was laid before the Council of the Royal Agricultural Society of England, at the meeting yesterday. If you can find room for it, I shall feel obliged.

I am, Sir, yours sincerely,

Long Sutton, May 6, 1853.

J. A. CLARKE.

TO THE COUNCIL OF THE ROYAL AGRICULTURAL SOCIETY.

GENTLEMEN,—As the judges of thrashing-machines at Chester are likely to have an unparalleled amount of labour to perform, if left to investigate, without previous plan or agreement, the many points of excellence and defect in those complicated pieces of mechanism, and the varied processes they perform, I am induced to recommend the preparation of a *table, or schedule of points for observation.* This would be at once a concise form of "Instructions for the Judges," saving them much time in discussion as to the basis of their examination, and a valuable statistical detail of facts and criticism for the public.

The *performances* of the machines are ascertained by the "trials," and the *mechanical principles and construction* are judged of by inspection; the prizes being awarded to those machines which, in the opinion of the adjudicators, possess the largest balance of advantages. Now, to shorten the duration of trial in work is not desirable; because, the longer a machine is engaged in thrashing, the better chance will there be of discovering its capabilities for shaking, riddling, and winnowing efficiently. But much of the time occupied in examining the mechanical merits and workmanship may be economized, I believe, by means of a *systematic*, instead of a cursory, inspection of the constructive details. To sum up the comparative merits of a great number of machines, from any notes of good or faulty "points" which may have been jotted down whilst looking at each, must often be difficult enough. How much simpler to have in your hand a list of the different conditions or capabilities to be looked for and considered in every machine brought before you, and just note under each head your opinion of the relative merit of each machine in that particular respect!

A table might be drawn up, stating the relative standing of the various machines, as regards *mechanical merit* and points which cannot be determined in mere trials, thus:

Name of Exhibitor.	Horse-power required to Drive the Machine *Empty*, at 120 revolutions of the Engine per Minute.	Horse-power required to Thrash at the Rate of 10 Sheaves per Minute.	Simplicity of Working-Parts.	Steadiness and Freedom from Liability to Wear.	Strength and Durability.	Weight, Compactness, and Portability.	Price.
—	—	—	2nd class	1st class	1st class	2nd class	—
—	—	—	1st class	2nd class	1st class	1st class	—
—	—	—	3rd class	1st class	1st class	1st class	—
—	—	—	1st class	1st class	2nd class	2nd class	—

The data in the second and third columns, ascertained by the dynamometer or testing-machine, would reveal certain excellencies or defects in the mechanism. For the next four columns (or more, as other points may be added), each machine must be inspected, and its rank as first, second, third class, &c., agreed upon by the judges, and noted under each head. The peculiar value of such a table would be, its containing the decision of qualified men upon the precise points that purchasers may be anxious about, and whatever qualities or merits the judges might finally consider important enough to carry off the prize. Still purchasers would know which machines excel or fail in every separate particular, and could therefore select the machine best suited to their peculiar district or business.

A tabular statement of *performances* we have had before; but I would suggest that the method of taking certain numbers to represent "perfect work" in each of the several operations, stating the degrees of merit of each machine by proportional numbers, and adding the figures together for the "total comparative merit," must necessarily give a fallacious result. Who is to say that when "clean thrashing" is represented by 20, "clean shaking" is to be set down at 15, "chafings free from corn" at 15, "chaff free from corn" 15, "corn unbroken" 12, "straw unbroken" 8?

It is easy to see that by assigning other arbitrary numerals for the different points, according to the view we may happen to take of their relative importance, very different sums-total of "comparative merit" would be obtained for the several machines tried. Instead of "unbroken straw" (for instance) being a point of more than half the merit of "clean shaking" or "chafings free from corn," in some localities farmers want their straw broken; and considerable difference of opinion may exist as to the relative value of perfection in knocking-out, shaking, and riddling.

Let the proportional merit of the machines in each process be stated, without attempting to calculate a comparative total of excellence or inferiority, the table of performances being somewhat as follows:—

Name of Exhibitor.	Number of Sheaves thrashed in half-an-hour.	Corn thrashed. Best Grain. st. lb.	Corn thrashed. Tail. lb. oz.	Corn thrashed. Screenings. lb. oz.	Clean thrashed.	Clean shaken.	Chafings free from Corn.	Chaff free from Corn.	Corn unbroken, or state of Barley.	State of Straw.	State of Shaker after trial.	State of Riddles after trial.
					PERFECT WORK REPRESENTED BY							
					10	10	10	10	10			
	000	00 00	00 00	00 00	10	8	10	8	6	Much broken.	Choked.	Not clear.
	000	00 00	00 00	00 00	8	6	10	6	10	Broken.	Clear.	Foul.
	000	00 00	00 00	00 00	10	10	8	10	10	Whole.	Not clear.	Clear.

Other points may be added, as, the quantity of "white-heads," the due separation of chafings from the long straw, freedom of the chaff from chafings, &c.

The average time worked by each machine at Carlisle was 15½ minutes with wheat, and 8½ minutes with barley; and seeing that at Salisbury there were forty combined machines, besides simple portable and fixed barnworks, it is hardly to be

expected that much more time can be allowed for each trial at Chester. But whether a quarter or half-an-hour, I consider that *each machine should be run for the same space of time;* instead of thrashing a certain fixed number of sheaves, so that at Carlisle one machine ran 22 minutes, while another was only 11 minutes doing the same work. The clear or choking condition of shaker and riddles is often apparent only after a certain period has elapsed in working; hence let the time be the same for all the machines, and the sheaves counted to the feeder. The quantity of corn thrashed, and the efficiency of the finishing dressing, should be ascertained by weighing off the several bags as they fill, which may be readily done. Inspection will suffice for determining the amount of corn left unthrashed in the straw, the corn carried over the shaker instead of dropping through, the state of the straw, the condition of the grain as to splitting, nibbing, &c.; but for detecting the presence of corn among the chafings and chaff, *these products ought to be put through a common dressing-machine or chaff-screen, worked by hand.* I believe that dressing all, or a certain quantity of, the chafings and chaff separately in this way, would reveal a great, though unsuspected, waste of corn by most thrashing-machines; and the precise proportion of this loss would be at once ascertained, when little or none might be apparent to mere inspection of the refuse from the riddles and winnower.

Numbers may be employed to denote the comparative degrees of efficiency in the several operations performed, provided they are not taken in the aggregate as indicating the general effectiveness of the machines.

In the two last columns of the table are given *the state of the shaker* and *the state of the riddles* when the trial is concluded—very important points; for in few machines can be found a shaker or riddle incapable of choking with straws and short refuse: though, nevertheless, effective shaking, coldering, and chaffing throughout a heavy day's work depend entirely upon the ability of the riddles and shaker to maintain their apertures clear and open.

The above suggestions are offered in no spirit of dictation, but simply with a desire to facilitate the labour of the judges; while at the same time securing a scrutiny and record of details useful to the public.

I beg to subscribe myself, gentlemen,

Yours respectfully,

JOHN ALGERNON CLARKE.

Long Sutton, Lincolnshire,
May 3rd, 1858.

THE VETERINARY COLLEGE IN RELATION TO AGRICULTURE.

The alliance, continual communication, or mutual dependence of one on the other, between Agriculture and the Veterinary Art, is even now by no means as close as it should be. It is not, indeed, so very long since, that the passed man from the College devoted himself almost entirely to the better sorts of horseflesh, while "the cow-doctor" still claimed nearly all the practice on the farm. It would be hard to say who is to blame here. In the earlier history of the College the aid of the veterinarian was of course not everywhere obtainable; and there are yet many districts where he is scarcely within hail. Farmers had so to put up with the best advice they could command at home, and the old village-farrier continued to kill with impunity. But times have altered with us in more ways than one. Year after year there are more and more qualified practitioners sent forth, and pari passu the value of our different kinds of stock has as certainly increased. The health of a Shorthorn heifer may be quite as important a matter as that of a four-year-old hunter, and a Southdown ram as well worth attending to as a half-bred stallion. The registered V. S., then, should be brought to consider the diseases of cattle as one of the most prominent points of his profession.

We shall most likely be assured that he does do so. We repeat, however, that the communication between the farm and the college is not so direct or habitual as the proper interests of either should make it. The Royal Agricultural Society has, to be sure, done everything it can to improve on this acquaintance, but with no very lasting effect. Every now and then Professor Simonds will give us a lecture, or a peculiar case will turn up which creates a temporary impression. Honestly, even this is, more often than not, a volunteer offering on the part of science, rather than in answer to any application from the farmer himself. As we have had occasion to say before now, the members of the Society are but too indifferent to the privileges they command in connection with the Veterinary College.

There has been lately rather a striking example of this. The London Farmers' Club called a discussion on the diseases of lambs. Despite the number of sheep fairs being held about the same time, some very good men answered the summons. They came, however, all with the same object—to learn. The very gentleman who read the opening paper could do little more than complain of his losses, and lament the curious character of the disorder. Mr. Marshall's speech was but the key-note to what followed. The meeting was palpably at sea as to suggesting a remedy; and one looks in vain for any resolution to that effect. The only preventive Mr. Paull had been able to find was to change the lambs on pastures fed by beasts the previous year. This had sometimes produced effect, but still he had been a great sufferer. Captain Davy removed his lambs to the after-grass, but had suffered very much from the malady. Mr. Owen Wallis attributed the evil to over-stocking. Mr. Little knew nothing of the disease in question. Mr. Williams said the diseases of sheep appeared beyond the aid of the veterinary surgeon. Mr. King had been advised to allow his flock of lambs to run over two or three fields of wheat, and the result was that he lost more lambs in this way than when they were shut in. Mr. James thought that where there was a couple of lambs there was more disease and mortality than with a single one. And Mr. Owen, the chairman, fancied the state of the blood had a great deal to do with the kind of disorder in his lambs.

Now in the whole of this discussion the opinion of but one veterinary surgeon was quoted. This was by Mr. Marshall, who gave a report from Mr. Jekyll of the post mortem examination of some lambs that had died of consumption. It is satisfactory to know, as we do, that the gentleman so called in is of recognised ability in his profession. He speaks to the thread-like worms found in the lambs; but unfortunately his research would seem, so far at least, to justify Mr

Williams' opinion that the sheep is beyond the aid of veterinary art. Mr. Jekyll can only say—"As a cure I have tried the internal exhibition of small doses of turpentine with cold gruel, but without success. I have also made them inhale chlorine gas; and the few on which I experimented recovered, but it was late in the season, and I think it likely they would have recovered without this. I intend, however, to make a further trial of this remedy; but while a ready means of cure is of importance to us, the cause and a preventive are of much greater. The history and stages through which these pests pass, and how they enter animal bodies, would very much aid us; but I fear all this is wrapped in a shroud of mystery so deep that science must labour long and perseveringly before she can bring forth the naked facts for the benefit of man." Mr. Marshall himself regretted that no one had given them the result of a post mortem examination of any of the lambs that had died in Berkshire, or the West of England; and Mr. Williams, despite his previous declaration, thought that if some dead lambs—say five or six from different farms—were sent to the Veterinary Professor of the Royal Agricultural Society for examination, he would with great pleasure do what was required. Mr. Corbet, the Secretary of the Club, said that the Professor had asked for such animals over and over again.

Let us now see what the Veterinary College has to say for itself. The week following the customary annual report from this Institution was read at the weekly Council Meeting of the Royal Agricultural Society. It will be found in another part of our paper of to-day. Parts of it would seem to have been written almost in direct answer to what occurred at the Club. As for example:—"From circumstances which would appear to be irremediable, few cattle are admitted as patients at the college. It is a matter of regret to the Governors that no measure which has been tried by them in conjunction with the Society has availed to bring to the College Infirmary a sufficient number of oxen, sheep, or pigs when the subjects of disease. Even the merely nominal scale of charges which was adopted a few years since for medical attendance, operations, keep, &c., of such animals, has failed in effecting this most desirable object; and the Governors are at a loss to know what more can be done to remove the apathy which exists in the agricultural body with reference to this important means of imparting practical information to the pupils." The Veterinary College has at any rate little doubt as to who is to blame for that want of intercommunication of which we complain.

Then, again, another clause in the report is equally well put, and as directly or more applicable to the wants of the farmer: "The visits into the country by the Veterinary Inspector, on the authority of the Council, have not been very numerous this year, and the Governors would be glad to see that the arrangement which has been made with regard to the inspection of diseased cattle on the premises of agriculturists was likewise in more general use, for they believe much good would result therefrom, not only in arresting the progress of disease, but in investigating the causes, with a view to their removal, on which it was found to depend."

Would it not have been better that a post mortem examination of a few of Mr. Marshall's lambs had been made under the authority of the Veterinary College? Or, that Mr. Simonds had been called in, to confer with Mr. Jekyll as to the nature of the disease? Might not Mr. King ask the College, quite as appropriately as the Club, "How he ought to treat his lambs?" Surely it is here that Practice should call in the aid of Science, in place of being simply content with changing to wheat or after-grass, and still being "a great sufferer." Ought we to rest satisfied, in this age, with discovering worms in the lungs of our sheep, but "how they got there we had never been able to find out?" The question, however, concerns alike the followers of either pursuit. A veterinary surgeon, of eminence in his district, admits that the disease has so far baffled his researches; while some of the sufferers speak of it as beyond the power of his art. Has this as yet been fairly or fully tested? The profession, in any case, should look to it. They report that they have now sent out more qualified students than in any previous year. Have these young gentlemen had the opportunity of studying consumption in sheep? If not, if Mr. Marshall, or Mr. King, or Mr. Paull will not send up their lambs, let the College send for them. Or, let Mr. Simonds pay either of these gentlemen a visit. We will answer for his reception. If there be "apathy" on the one side, there must be none on the other.

In some quarters, at any rate, the value and want of the Veterinary Art in connection with Agriculture is coming to be properly appreciated. At the late Show of the Dublin Society, one of the best points in the different addresses delivered is to be found in the speech of a practical agriculturist, Lord Talbot de Malahide:—"He thought it of the utmost importance that further attention should be given to veterinary science. He believed that one of the objects which the Highland Society had in view was the consideration of that subject; and of all the societies that he knew, he knew of none that could take that subject up with greater advantage than the Royal Dublin Society. But if it were to be done, it should be done effectually; it should not be done by having a few lectures, but by having a veterinary hospital; and it would be necessary to teach the science practically not only to those who were to be professors, but almost an equally important matter would be to have an inferior class in attendance, such as they found for nurses in hospitals, and a regular course of instruction should be given to those "nurses" over the welfare of the animal creation. He considered this subject one of national importance, and worthy the attention of every person who had the welfare of the country at heart."

Even here, in England, we may yet echo his Lordship, and impress upon our agriculturists the importance of paying more attention to Veterinary Science.

THE SOIL

The soil is the farmer's capital—to make it pay him good profits, his business. His means are invested in land, and from its generous bosom he must draw support for himself and family—house, food clothing, fuel, books, papers, education for his children—all the necessaries of life, without which man cannot live, and all those luxuries without which life is hardly worth the having. The President in the White House, our ministers at foreign courts, the American loungers in Paris or Rome, the missionary on the burning sands of Africa, the merchant in his counting-room, and the mechanic at his bench, all derive sustenance from American soil, Truly do the Scriptures say, "The profit of the earth is for all; the king himself is served by the field." This fact no political economist can deny, no sophism can conceal. To keep his capital from depreciation, and in such a condition that it may be able to honour his many and necessary drafts, so as to be in no danger of a panic, and that no suspension may become necessary, is the great business of the farmer. It is, then, of the greatest importance that we should know the *character* of the soil which a kind Providence has provided for our sustenance, and the best method of securing this desirable result.

We need not tell American farmers that our soil differs in character, that we have *clayey*, *loamy*, and *sandy* soils—nor that these different soils require a different treatment, and are suited to different crops. And yet we often think those important matters are forgotten; for how few, who send us reports of their crops, of their success, or their failures, give even a hint as to the nature of the soil in which the crops were grown, or the experiments tried! Then there is much need of information as to the best manner of cropping and manuring the different varieties of soil. We know of land in this section, that ten or fifteen years ago was considered so entirely unsuited to agricultural purposes that it was thought no sane man would buy it for farming purposes. Starvation or retreat was supposed to be the sure fate of any one bold enough to try the experiment. These lands are now the most productive and valuable of any in this part of the State. This change has been brought about by skilful culture and a wise adaptation of crops to the soil.

Every farmer should possess a general knowledge of the formation, composition, character, and classification of soil, and on these points we shall endeavour to make the whole subject so plain that it will be understood and remembered by all.

CHARACTER AND FORMATION OF SOILS.

Soils are those portions of the earth's surface which contain a mixture of mineral, animal, and vegetable substances in such proportions as to adapt them to the support of vegetation. We quote from a valuable article in *Morton's Encyclopedia*;

"On examining the various soils in this or any other country, they will be found to consist generally, 1. Of larger or smaller stones, sand or gravel. 2. Of a more friable, lighter mass, crumbling to powder when squeezed between the fingers, and rendering water muddy. 3. Of vegetable and animal remains (organic matter.)

"On further examination of the several portions obtained by means of washings, we find,

"1. That the sand, gravel, and fragments of stones vary according to the nature of the rocks from which they are derived. Quartz-sand, in one case, will be observed as the predominating constituent; in another, this portion of the soil consists principally of a calcareous sand; and, in a third, a simple inspection will enable us to recognize fragments of granite, feldspar, mica, and other minerals.

"2. In the impalpable powder, the chemist will readily distinguish principally fine clay, free silica, free alumina, more or less oxyde of iron, lime, magnesia, potash, soda, traces of oxyde of manganese, and phosphoric, sulphuric, and carbonic acids, with more or less organic matter.

"3. The watery solution of the soil, evaporated to dryness, leaves behind an inconsiderable residue, generally coloured brown by organic matters which may be driven off by heat. In the combustible or organic portion of this residue, the presence of ammonia, of humic, ulmic, crenic, and apocrenic acids (substances known under the more familiar name of soluble humus), and frequently traces of nitric acid, will be readily detected. In the incombustible portion, potash, soda, lime magnesia, phosphoric, sulphuric, and silicic acid, chlorine, and occasionally oxyde of iron and manganese, are present."

All cultivated soils present a great similarity in composition, all containing the above chemical constituents; and yet, notwithstanding this similarity of composition, we observe a great diversity in their character. This is caused by the different proportions in which the constituents are mixed together, the state of combination in which they occur, and the manner in which the different soils are formed. All arable soils contain organic matter, varying from half to twelve per cent. Good garden mould frequently contains from twenty to twenty-four per cent. of its own weight, and in peaty pogs from sixty to seventy per cent. is not uncommon. It was once thought that the richness of a soil was plainly indicated by the proportion of organic matter it contained; but careful analyses of seven specimens of the best wheat soils of Scotland, and yielding about alike, being made, they were found to range from three to ten per cent. The poorest peaty bogs, also, contain the greatest amount of organic matter, while they are notoriously unproductive.

The organic matter in the soil is due, for the greater part, to the vegetable remains of former crops.

The prairie soils are rich in organic matter derived from the annual decay of the grass for centuries. The soil of the forests is enriched by the fallen leaves.

The manner in which soils are formed cannot be doubted by any one who has observed the appearance of large rocky masses, the bare surface of their smoother and harder parts, and the growth of mosses and small plants on the more softened portions. The soil in valleys surrounded by rocky mountains shows very evidently that they originated in the disintegration and decomposition of the solid rocks in their neighbourhood. One of the principal agencies in effecting a gradual disintegration of solid rocks is the oxygen of the atmosphere. "Oxygen possesses a great affinity for many mineral substances, and has, consequently, a powerful tendency to form new compounds. Those compounds, or oxydes, being always more voluminous, looser, and less compact, are the primary cause of the bursting of many rocks, particularly of those containing much iron. In the course of the formation of these oxydes, the compact texture of the rock is broken up, and the whole mass of the rock gradually crumbles down."

Another and powerful agency in the formation of soils is the carbonic acid of the atmosphere carried down by rain. Limestone is easily attacked by rain water, as the carbonic acid which the water contains dissolves the carbonate of lime. "On feldspar, granite, and other minerals consisting of silicate of alumina and an alkaline silicate, carbonic acid and water exercise a highly important action. Under their influence these minerals are decomposed into alkaline silicates, which in their turn give rise to silica and carbonate of potash or soda, and into silicate of alumina, or pure clay."

The lower orders of plants and animals take a very active part in the formation of soil from solid rocks. The seeds of lichens and mosses floating in the air attach themselves to the surfaces of rocks which have become partially decomposed by the action of the air and rain, as before described, and finding here sufficient food, grow, thus keeping the surface of the rock moist for a longer time after rain, and giving the water a better opportunity to exercise its dissolving powers. Insects feed on the moss; and both insects and plants die and decay. A thin layer of more fertile soil is thus formed, which is soon taken possession of by a higher order of plants and animals; which in their turn die, leaving a better estate to the succeeding generation.

Mechanical causes, too, operate upon rocks. The wind, thawing and freezing, and the principle of gravitation, effect them more or less.—Rural New Yorker.

WHAT BECOMES OF THE BONES: THEIR USE AND COMMERCIAL VALUE.

Mr. Green, one of the many engaged in the business of calcining bones in New York, gives the following information as to the use and value of bones. Mr. Jones' boiling calcining establishment is situated on the Jersey side of the Hudson, sixteen miles up, nearly opposite Yonkers. To collect the bones from the *chiffonniers* he employs in this city eight men, eight horses, and four carts. A labourer invariably goes with each driver. The largest collections are made in the Eleventh, Seventeenth, Eighteenth, Nineteenth, Twentieth and Twenty-first, Wards. They commence their rounds as early as 7 a. m., and by 1 p. m. the collections are deposited in the vessel that is to convey them from the city. The law requires all the carts engaged in this business to be boxed or covered with canvas. The price paid for bones varies according to quality. Thigh bones of bullocks rank first, as they are the only bones in an ox that are fit for turners' use; they are mostly manufactured into handles for tooth brushes, the natural curve of the bone giving the desired shape to that indispensable article for the toilet. They are worth from ten to twelve cents each. The jaw bones rank next, and are worth 18 dollars a thousand. The "short" bones, as they are termed, such as leave the family table, are worth from 40 to 50 cents a basket. To give some idea of the amount of money paid for bones, when we consider the number engaged in the business of bone-boiling, exclusive of the Barren Island business, we will state that Mr. G. pays for bones in this city alone an average of 100 dollars a day. The fore leg and hoof are usually bought by manufacturers of glue, Peter Cooper being the heaviest purchaser of this description of offal; and when they are done with, they are sold to the bone dealers at two cents a pound. The hoofs are disposed of at the rate of 40 dollars a ton, and are afterwards made into *horn* buttons and Prussian blue. Horse hoofs and sheep hoofs and horns are sold at 15 dollars a ton.

On the arrival of the bones at the factory, the thigh and jaw bones are sawn so as to admit of the removal of the marrow. They are then thrown into a vast cauldron, and boiled until all the marrow and fatty substances attached to them are thoroughly extracted. The fat is then skimmed off and placed in coolers, and the bones are deposited in heaps for assortment. The thigh bones are placed in one heap for the turners: the jaws and other bones suitable for buttons are placed in a second pile: the bones suitable for "bone black" come No. 3, and the remainder are ground up for phosphates and manures.

"Bone black" is used by sugar-refiners, and is worth from 2½ to 3½ cents a pound. To judge of the amount used in this city alone of this article, in the eleven immense sugar refineries in operation here, it is only necessary to state that "Stuart's" and the "Grocers'" refineries pay annually in the neighbourhood of the city 40,000 dollars a year each for "bone black."

Of classes Nos. 2 and 3 we were furnished with no reliable data. No. 2 is used in the manufacture of phosphates. No. 3 is made into manure, and sold at prices ranging from 38 to 55 cents a bushel,

according to quality, but generally averaging about 50 cents, delivered at the factory.

Of the amount of soap-fat produced from bone-boiling, we can only say that our informant showed by his books that the sale of soap-fat from his factory from June, 1856, to June, 1857, amounted to 19,000. dollars Of this amount 14,000 dollars was paid by one house, and we were assured that this was but a moiety of the amount the house annually purchased.—Hunt's American Mrchant's Magazine.

SALE OF MR. CARTWRIGHT'S HERD OF SHORT-HORNS, AT AYNHOE.

BY MR. STRAFFORD.

On Wednesday, May 5, the entire herd of short-horns, belonging to T. R. B. Cartwright, Esq., of Aynhoe, were sold by auction, without reserve, at the Home Farm, Aynhoe, by Mr. Strafford, the well-known stock auctioneer, of London. There were 46 head of very fine cattle, most of which were purchased by gentlemen from a distance, at very high prices. This splendid herd has all been collected by Mr. Cartwright within the last four years, and is now broken up, we understand, preparatory to his disposing of the farm on which they have been reared. The cattle showed very plainly what can be done by skill and judgment, coupled with untiring perseverance and industry; for, without exaggeration, we can safely say that Mr. Cartwright in his breeding of shorthorns has rivalled his compeers, even the oldest and most famous. It was matter of general remark by the very numerous party present, that they never saw stock look so well—and although cattle have been sinking in price of late, the prices were larger than at any sale in the kingdom of this year. Some of those sold are destined for Australia, Mr. Tyrell, agent for Mrs. Keith Faulkner, of Torquay, buying several for that purpose. The Prince of Prussia bull was bought for the Royal Agricultural College, at Cirencester. But we were rather astonished to observe that the breeders of this neighbourhood allowed so much excellent blood to leave the district; for it is but seldom that such an opportunity occurs when they can obtain really good stock at their own doors. No doubt the prices obtained were very high; but it ought always to be considered that for such good old blood as that of "Venus" (Lot 12), and "Hero" (Lot 8), an extra price must be paid. "Usurpation," a first-rate cow, sold for £110 to a gentleman from Lancashire. The Yearlings generally fetched high prices; but "Genevieve 3rd," "Augusta," and "Juanita" (who might be considered as the gems of the sale), sold at extraordinary prices for their age. The bulls, 11 in number, were admirable animals; but Lot 1, "Second Duke of Cambridge," although he sold for £147, did not realize so much as he deserved, especially when it is remembered, as stated by Mr. Strafford, in beginning the sale, that his sire, "Grand Duke," was sold for no less than 1,000 guineas.

As a proof of the wide-spreading taste for shorthorns, it may be observed that the Essex men, who have hitherto rather held aloof, were good buyers: another earnest that the seed which was sown by the Royal Agricultural Society in 1856 has not fallen on a barren soil. A new purchaser also arose in Mr. Howard of Biddenham, a brother of the celebrated implement maker, at Bedford, who carried off four of the choicest-bred things, at long prices. One of these was Lady Spencer, a twelve-year-old, and consequently a rather ragged-looking cow (whose dam was bought at Mason's sale at Chilton in 1829), bearing in her veins the blood of Monarch, who was sold for 220 gs. in very low-price times. One of her three daughters, Lady Spencer 2nd, by the 400-guinea Usurer, and whose young calf was said to have been sold that morning for 50 gs., also becomes Mr. Howard's at 105 gs. Her daughter, Lady Spencer 4th, a proof of the high quality of the Usurper heifers, was, again, the subject of very fierce competition; but the Master of the Heythrop Hunt was not to be choked off, and he got the last nod for 140 gs. Lady Spencer 1st was not so fortunate, although a very magnificent animal to look at; but owing to a general impression that she could be of no use for breeding, Mr. Cartwright lost 70 gs. on the price which he gave for her a short time since. Lady Franklin, one of the best cows in the sale, did not realize her original price by a great deal. She was by Captain Shaftoe, a Royal Show pure bull at Northampton, who was sold twice over for upwards of 300 gs. Junia was much liked, and so was her magnificent calf Juanita, by Second Duke of Cambridge; but the colour of Snowdrop, who was purchased by Lord Southampton, was not a little against her in the biddings. Genevieve, by the Second Duke of Cambridge, would not improbably have followed suit to Whittlebury, but his lordship cut it rather too fine, and the last grain had fallen from the glass in favour of the Duke of Marlborough's steward, before he renewed his bid. Grand as the Second Duke of Cambridge's stock were, the Duke himself is slightly leggy, and has hardly made up into quite the animal we originally expected; but still Mr. Phillips showed good judgment in taking him at the price into Devon, along with Lady Spencer the First. His son John O'Gaunt was a very striking animal, with a rare back and quarters, and very rich hair; and Mr. Lawford, of Leighton Buzzard, one of the last competitors for the old bull, bought him. As at the Tubney and first Quorn sales of horses, the highest prices were a bracket, in this case, of 140 guineas, between Lady Spencer 4th and the Second Duke of Cambridge.

The company present numbered at least between 200 and 300, many of them from distant counties, and the rest were the most enterprising breeders of cattle and agriculturists of the neighbourhood. Such an assembly is seldom seen in this quarter, and shows the great interest now taken in shorthorned cattle. Amongst the noblemen and gentlemen were —Lord Southampton, Sir Charles Knightley, Bart., H. W. Dashwood, Esq., W. Willes, Esq., H. L. Gaskell, Esq., Kiddington Hall; Col. Bowles, J. L. Stratton, Esq., T. E, and G. Drake, Esqrs., H. Hall, Esq., the Hon. H. Noel Hill, Shropshire; Mr. Denchfield, agent to Sir Anthony Rothschild, Bucks; Mr. Mein, agent to the Duke of Marlborough; Mr. Tyrell, agent to Mrs. Keith Faulkner, Torquay; Mr. Turvile, agent to W. Bramston, Esq., M.P., Essex; Mr. Willoughby Wood, Holly Bank, the well-known agriculturist; Mr. Lowndes, Liverpool; Mr. J. C. Adkins, Milcote, Warwickshire; Mr. Topham, Warwickshire; Mr. Dodwell, Long Crendon; Mr. Bowley, Cirencester; Mr. S. Bracher, Shaftesbury; Mr. W. Smyth, Wadhurst Castle, Sussex; Mr. Lawford

Leighton Buzzard; Mr. Yorke, Thrapston; Mr. Beale, Rugby; Mr. Piggott, Essex; Mr. Atherton, Liverpool; Mr. J. Robinson, Clifton Pastures, Bucks; Mr. Christy, Essex; Mr. Howard, Bedford; Mr. Longland, Northamptonshire; Mr. Phillips, Broombury, Totnes, Devon; Mr. H. Hewers, Northleach; Mr. T. Worsey, Chapel House, Speke, Lancashire Mr. T. Robinson, Castle Ashby, Northamptonshire, &c., &c,

After the company had partaken of a substantial luncheon, they inspected the crops on the farm, which are now in a very forward state, the barley sown in December looking better than any ever seen in this quarter before; the winter beans are in flower; and the wheat, drilled three pecks to the acre, is a very promising crop. Mr. Strafford then took his place on the stand, and after reading the conditions of sale, went on to remark "that he was quite sure he need say nothing to recommend the stock to the notice of the company, for the large number of breeders and farmers he saw before him, from all parts of the country, satisfied him that when a man went the right way to work, like Mr. Cartwright, his efforts would be fully appreciated. Mr. Cartwright had done wonders during the short time he had been a breeder. The stock which he had to offer on that occasion was remarkably well bred, and those who were desirous of commencing the breed of Shorthorns had now an excellent opportunity of doing so. He believed that Shorthorns were destined to supersede every other breed. In conclusion, he begged to say that the whole of the stock would be sold without reserve." The biddings commenced, and went on very spiritedly to the end, Lord Southampton and Mr. Mein, agent to the Duke of Marlborough, bidding against each other very obstinately at times. We subjoin the lots and the prices obtained:—

COWS AND HEIFERS.

Lot 1.—Jacinth, roan, calved in March, 1846; got by Fawsley; bought for £38 17s., by Mr. W. Hadland, of Clattercote.

Lot 2.—Flash, red and white, calved in Sept., 1846; got by Mowbray; £25 4s., by Mr. E. Parsons, of Walton Grounds.

Lot 3.—Lady Spencer, roan, calved in Dec., 1846; got by Shamrock; £68 5s., by Mr. Phillips, Broombury, Totness, Devon.

Lot 4.—Jenny Lind, red, calved March, 1847; got by Duke of Richmond; £47 5s, by Mr. Robinson, Castle Ashby, Northamptonshire.

Lot 5.—Joan, red, calved August, 1847; got by Lycurgus; £42, by Mr. Worsey, Chapel House, Speke, Lancashire.

Lot 6.—Garland, red, calved November, 1847; got by Brunswick; £38 17s., by Mr. Bowley, Siddington House, Cirencester.

Lot 7.—Pearl 2nd, roan, calved April, 1848; got by Senator, £44 2s., by Mr. H. Hewer, Northleach.

Lot 8.—Hero, roan, calved May, 1848; got by Son of the Baronet; £38 7s., by Mr. W. Caless, Bodicote House.

Lot 9.—Day's Eye, roan, calved May, 1849; got by Young Fourth Duke; £69 6s., by Mr. Howard, Bedford.

Lot 10.—Lady Spencer 1st, roan, calved June, 1850; got by Marquis of Rockingham; £42, by Mr. Phillips, Broombury, Totness, Devon.

Lot 11.—Pearl 4th, white, calved October, 1850; got by Benedict; £48 6s., by Mr. Howard, Bedford.

Lot 12.—Venus, red and white, calved June, 1852; got by Grand Duke; £105, by Mr. H. Hall, Barton.

Lot 13.—Lady Franklin, red, calved July, 1852; got by Captain Shaftoe; £70 7s., by Mr. W. Caless, Bodicote House.

Lot 14.—Accession, roan, calved June, 1853; got by Filbert; £31 10s., by Mrs. Keith Faulkner, Torquay.

Lot 15.—Pearl Powder, red and white, calved October, 1853; got by Buccaneer; £36 15s, by Mr. Longland, Northamptonshire.

Lot 16.—Fashion, roan, calved November, 1853; got by Daybreak; £52 10s., by Mr. Avery.

Lot 17.—Lady Spencer 2nd, roan, calved November, 1854; got by Usurer; £110 5s., by Mr. Howard, Bedford.

Lot 18.—Genevieve 1st, red and white, calved December, 1854; got by Usurper; £55 13s., by Mr. Christy, Essex.

Lot 19.—Jocose, red and white, calved March, 1855; got by Usurper; £73 10s., by Mrs. Keith Faulkner, Torquay.

Lot 20.—Junia, red, calved April, 1855; got by Duke of Gloster; £95 11s, by Mr. J. Robinson, Clifton Pastures, Bucks.

Lot 21.—Usurpation, roan, calved October, 1855; got by Usurper; £110 5s., by Mr. Atherton, Liverpool.

Lot 22.—Lady Spencer 4th, roan, calved December, 1855; got by Usurper; £147, by Mr. H. Hall, Barton.

Lot 23.—Genevieve 2nd, red and white, calved Jan. 21, 1856; got by Usurper; £75 12s, by Mr. Piggott, Essex.

Lot 24.—Jilt, roan, calved March 18, 1856; got by Usurper; £105, by Mr. H. Hall, Barton.

Lot 25.—Johanna, red, calved June 25, 1856; got by Usurper; £34, by Mr. J. Robinson, Bucks.

Lot 26.—Adelaide, red and white, calved Oct., 1856; got by Usurper; £32 11s., by H. L. Gaskell, Esq., of Kiddington Hall.

Lot 27.—Violet, red and white, calved Nov., 1856; got by Usurper; £73 10s, by Sir Anthony Rothschild, Bucks.

Lot 28.—Princess Royal, roan, calved Feb., 1857; got by Usurper; £13 1s., by H. L. Gaskell, Esq., Kiddington.

Lot 29.—Jessica, red and white, calved Feb., 1857; got by Usurper; £59 17s., by Mr. Howard, Bedford.

Lot 30.—Proserpine, roan, calved March, 1857; got by Brilliant; £63, by Mr. Piggott, Essex.

Lot 31.—Snowdrop, white, calved March, 1857; got by Brilliant; £58 16s., by Lord Southampton, Whittlebury.

Lot 32.—Genevieve 3rd, red and white, calved July, 1857; got by Second Duke of Cambridge; £110 5s., by the Duke of Marlborough, Blenheim.

Lot 33.—Augusta, roan, calved Sept., 1857; got by Second Duke of Cambridge; £34, by Lord Southampton.

Lot 34.—Juanita, red and white, calved Sept., 1857; got by Second Duke of Cambridge; £35 1s., by Mr. H. Starkey, Spy Park, Wilts.

Lot 35.—Dewdrop, roan, calved March, 1858; got by Second Duke of Cambridge; £34 13s., by Mr. Starkey, Wilts.

BULLS.

Lot 1.—Second Duke of Cambridge, red, calved April, 1854; got by Grand Duke; £147, by Mr. Phillips, Totness, Devon.

Lot 2.—Flamer, red and white, calved August, 1856; got by Usurper; £28 7s., by Sir Anthony Rothschild, Bucks.

Lot 3.—Potentate, red, calved Jan., 1857; got by Usurper; £32 11s., by Mr. Beale, Rugby.

Lot 4.—Forester, red and white, calved June, 1857; got by Second Duke of Cambridge; £43 1s., by Mr. H. Clarke.

Lot 5.—Firebrand, red and white, calved June, 1857; got by Second Duke of Cambridge; £38 17s., by Mr. Yorke, Thrapston.

Lot 6.—Freebooter, red, calved August, 1857; got by Second Duke of Cambridge; £32 11s., by Mr. Painter, Worton.

Lot 7.—John o'Gaunt, red, calved August, 1857; got by Second Duke of Cambridge; £119 5s., by Mr. Lawford, Leighton Buzzard.

Lot 8.—Don Juan, red, calved August, 1857; got by Second Duke of Cambridge; £35 1s, by Mr. W. Smyth, Wadhurst Castle, Sussex.

Lot 9.—Jester, red and white, calved Sept., 1857; got by Second Duke of Cambridge; £49 7s, by Mr. Stephen Bracher, Shaftesbury.

Lot 10.—Lord Althorp 3rd, red, calved Dec., 1857; got by Second Duke of Cambridge; £36 15s., by Mrs. Keith Faulkner.

Lot 11.—Prince of Prussia, red roan, calved Jan., 1858; got by Second Duke of Cambridge; £37 16s., by Mr. Bowly, Cirencester.

The total realized by the cows and heifers was £2,290 1s. giving an average of £65 8s. 7d. The bulls fetched £641 1s., and an average of £58 6s. 5½d. The grand total proceeds of the sale was £2,931 2s., which gives an average of £63 14s. 7½d.

After Mr. Cartwright's sale had been concluded, six shorthorns, bred by P. S. Punnett, Esq., Chart Sutton, were sold by Mr. Strafford, as follows:—

Lot 1.—Young Mary, red and white, calved in 1850; got by Man of Kent; £35 14s., by Mr. Chamberlin, of Adderbury.

Lot 2.—Roan Crummy, rich roan, calved in 1851; got by Man of Kent; £32 11s., by Mr. Bowley, Cirencester.

Lot 3.—Young Spectator, roan, calved in 1852; got by Murton; £34 13s., by Mr. Caless, Bodicote.

Lot 4.—Torrington, roan, calved in 1852; got by Man of Kent; £29 8s., by Mr. Willifer, King's Sutton.

Lot 5.—Young Humpsey, roan, calved in December, 1853; got by Murton; £49 8s., by H. L. Gaskell, Esq., Kiddington.

Lot 6.—Locket, white, calved in April, 1855; got by Highland Laddie; £26 5s., by Mr. W. Smyth, Sussex.

The total amounted to £187 19s.; and the average, £31 6s. 6d.

EXPERIMENTAL FARMS IN AUSTRALIA.—It is with great pleasure that we take cognizance of the appointment of Mr. Skilling to the office of Director of the Experimental Farm, to which a portion of the Government grant in aid of agriculture has been devoted. We feel convinced that

this accord to the wishes of our farming community will be gratefully received, as it tends to prove that those in authority are really anxious for the success of the scheme propounded. Mr. Skilling has, for some time, been the industrious and efficient secretary of the Port Philip Farmers' Society, and by constant contact with our leading agriculturists has become so thoroughly acquainted with their views, and their pursuits, that he is singularly qualified for the post he is now called upon to fill. Had the original idea of *Importing (!)* a director from England been carried out, however good a practical or theoretical husbandman he might be, it would have been years before he could have proved himself thoroughly a master of the peculiarities of our soil and climate as to become useful to the colony at large. In place of teaching, he would have to learn from the very farm servants who might already be acclimated, and, however anxious to do his duty, must have necessarily found himself a temporary stumbling-block, instead of assistance, to our already rapid advancement. We are not aware if the Port Philip Farmers' Society will immediately lose the services of their able secretary, though we should imagine so; but, much as the removal will be regretted by those to whom he has been so faithful a colleague, we are sure that the extended means of usefulness thus opened to him will be hailed with gratification, as a reward due to merit, and also as a handsome compliment to the society itself. When the question of the grant was first mooted, Mr. Skilling penned an able memorial to Captain Clarke, setting forth the advantages to be gained by a model farm, and in a full, but concise manner, explained the objects to be desired, and the most feasible method of carrying them out. The plan of a museum he also broached, and particularly impressed on the government the mutual economy and benefit to be acquired by a reformatory school attached to the institution, an idea which it were well to embrace. The almost unexpected recognition of his valuable advice, and in so highly complimentary a form, will, we doubt not, be a spur to Mr. Skilling's future exertions, and we shortly hope to see him prove as able in practice as precept.—*Bell's Life in Victoria.*

THE REARING AND DISEASES OF LAMBS.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—On reading your report of the discussion on the rearing and diseases of lambs at the Farmers' Club, I find that several gentlemen have sustained great losses amongst their lambs, but none have been able to supply a remedy. I have therefore been induced to send you the result of my own experience, in order that others may benefit from it, if they choose to use the remedy, which is both simple and inexpensive, and in my own case effectual.

In the beginning of April, 1852, my lambs were affected much in the same way as the Chairman describes his to have been. The first symptoms (where they were observed) were, a wandering listless gait, with the head down, and the mouth in motion as if eating; when, suddenly, they would make a start, stagger a few steps, then fall down and struggle violently for a short time, foaming at the mouth and gnashing the teeth as if in great pain. These paroxysms with some of them lasted but a short time—death eased their pain; and, almost invariably, with death came what was termed the scour. In others it appeared with less violence, and some I had lingered for days before they died. With these I tried every remedy I could think of, or that was suggested to me; and, unfortunately, I had cases enough to try everybody's remedy. But all were alike unavailing, and the disease was stopped at last by weaning, and at the same time spoiling those that were left. I find, on reference to notes made at the time, that from the beginning to the 23rd of April (the time of weaning) I had lost 80 out of 300 lambs. The stomachs of several of the lambs were examined by two veterinary surgeons without any satisfactory result. I should state, perhaps, that during these three weeks of mortality, in hopes of checking the disease, the flock was moved from old or early sown swedes to younger ones that had been pulled up and put in rows across the field, and the ground ploughed between; so that it was impossible they should have picked up any weed to occasion the disaster. Next they were put on young turnip greens, and after that on ryegrass, until, on the 23rd, they were taken from their mothers and kept on dry food for a few days, weaned, and spoiled; but the disease was stayed. From this I felt convinced that the injury was derived from the ewe, and that it was she who required medicine; and, having seen in "Clater's Cattle Doctor" that two ounces of Glauber's salts, with a quarter of an ounce of carraways, mixed with thin gruel, was a good aperient dose for a sheep, I resolved to give it a trial, which I had an opportunity of doing the following year; and, as I believe, prevented a repetition of the previous year's loss, as the same symptoms, attended with the same fatal result, had shown in one of the best lambs (which I think is often the case): upon which I procured a quantity of salts and carraways, and drenched all the ewes in the flock, excepting six which had not lambed at the time; and the only lamb I lost in a similar way afterwards was from one of these six ewes.

The way in which I prepare the dose is this: I first boil the carraways in order that the extract may be equally administered, which it would be more difficult to do with the seeds. When the carraways are sufficiently boiled, add cold water enough to make as many half-pints as there are sheep to be drenched; then add the salts (two ounces to each half-pint), which, when dissolved, I give to the ewes from half-pint bottles, which a boy or girl will fill as fast as five or six men will get them emptied by drenching the ewes.

I am afraid, Sir, that my communication has extended to too great a length; but I have endeavoured to be as concise as possible, and have only said as much as I thought was necessary in order to be understood, and I must trust to your advocacy of the agricultural interest to plead my apology.

I remain, Sir, your obedient servant,

Burgholere, May 14th, 1858. ROBERT CHURCH.

THE DISEASES OF LAMBS.

SIR,—I have read the discussion at the Central Farmers' Club published in your paper this week, and find that some farmers have lost a number of lambs in a short time. Having had some practice in this matter, and knowing the cause of death and the cure, I will tell it you for the benefit of my brother-farmers. It is caused by a feverish milk from the ewe. The cure is 1 oz. of salts to each ewe, and good keeping. If a single death happens after this, another ounce per ewe must be given. I have proved it. To keep well, without cooling the blood of the ewe, is certain death to an increased number of lambs. I am, Sir, your obedient servant,

Woolston, Bletchley Station, May 11th. W. SMITH.

SOMETHING OF PLANTS, AND HOW THEY LIVE.

Plants feed themselves. They increase in stature because of nourishment. They receive what is required, and discharge from their roots what is not required, to assist their growth. What are plants made of? If every farmer could answer this question, and then provide the pet plant with such matter as it requires in the manufacture of itself, he would disperse a mist in which at least nine-tenths of our farmers are bewildered. Burn any dry vegetable matter. What becomes of it? You see nothing but ashes. This is not all of it. The balance has become dissipated in the atmosphere. That part which is nowhere—which has escaped in the air, or burned away, is the *organic* part—the ashes the *inorganic* portion. Where did this plant come from? "Dust thou art, and unto dust shalt thou return." The part become air must have originated in air; while the ashes have become earth, and originated in the soil. The *organic* part is air, the *inorganic* matter earth. Remember it. Nothing is lost. There has been no annihilation—only a change of form. The *organic* matter, which has burned away, consists of *carbon, oxygen, hydrogen,* and *nitrogen. Carbon* is a solid (charcoal), and the last three named are gases. Carbon exists in all plants, and in combination with these gases constitute nearly the whole of most plants, ashes bearing but a small proportion to the whole. Carbon constitutes about half the dry weight of plants. *Oxygen* supports combustion. It unites with many substances. It is sometimes called *vital air,* because necessary to respiration. Oxygen and carbon form carbonic acid, and united with hydrogen forms water. When united with iron, the iron becomes rusty. This rust is called oxide of iron. Oxygen united with nitrogen forms nitric acid. The two also compose atmospheric air; and here witness the wonderful adaptation of the works of creation to each other! If the atmosphere was pure oxygen, every living thing would soon decay of combustion; but adding to one part of oxygen four parts of nitrogen, God has so diluted the exhilarating gas, as that in its place we have a delicious life-giving and life-preserving nectar—so pure and palatable that we never cease to thirst for it, yet the supply is ample. But there are other elements in the atmosphere which the lungs of plants receive, and yet they are called impurities. We have seen farmers for the want of the proper knowledge apply certain compositions to a soil, when, instead of benefiting the plant, it drove away, and dissipated all that was giving life to it. We have seen *ammonia,* one of the impurities above alluded to, allowed to escape from a manure heap, because of the want of the proper application to fix it there. *Carbonic acid, water,* and *ammonia* are all essential to the maturity of most vegetables. *Carbonic acid* is the most important in its relations to plants, for from this source alone is their carbon obtained. It consists, as has been said, of *carbon* and *oxygen.* It is remarkable as being the first gaseous substance recognized after atmospheric air. Dr. Black, in 1757, called it *fixed air,* because he found it fixed in common limestone and magnesia. Plants, as we have before said, receive nourishment through their roots, and by their leaves. Carbon enters in the water by the roots, and is absorbed from the air by the leaves. Since carbonic acid is the source of supply of carbon only, to the plant, the *oxygen* must be separated from the carbon, and sent off into the atmosphere. The gum portions of the plant exhales the oxygen under the influence of sunlight. Sunlight is essential to the decomposition of carbonic acid, and to the rapid growth of plants. When a plant decays, the carbon in the plant unites with the oxygen in the air, and becomes carbonic acid. The same is the result where bodies burn. In the consumption of food and respiration, you are manufacturing and throwing off carbonic acid, which goes to assist again the formations of food for yourself or your dependants. Carbon then is certainly in a transition state, and though it constitutes so large a part of all vegetable and animal matter, yet it is all derived from the small amount of carbonic acid in the atmosphere; and but for this constant change and exhalation of both plants and animals, the supply would be exhausted. The fire in your kitchen is constantly supplying the trees and vegetables near your door with carbonic acid, which if exposed to the sun decomposes rapidly, and hence makes a rapid growth. The tree near your dwelling, though no better than the one planted at the same time, in the same manner, and in equally as good soil, in the orchard fifty yards distant, is far outstripping the orchard tree in growth—simply because it is fed with more carbon. Trees are necessary near the house; and in large cities, every man who understands the laws of nature and of health will provide these absorbents for the extra amount of acid generated. We frequently find in cities the leaves of plants rapidly forming, while in the country the twigs are as bare of foliage as at mid-winter. We should not be misunderstood. Carbon enters the plant in the form of carbonic acid. The *carbon* is retained until the plant decays, but the oxygen is thrown off to unite with carbon again. Carbon is *fixed* in the plant until decay commences. The blood of animals, which contains carbon, unites with the air, or the oxygen of the air, as it is inhaled into the lungs, and forms carbonic acid, without which process no animal could live. This carbonic acid is thrown off, and feeds plants, which in turn feed animals again.

We have said carbon is a solid, or, in other words, *charcoal* is a solid. It is light and porous, hence a good absorbent. This is the secret of its value to the farmer. It absorbs gases that may escape from plants or decomposing substances. It separates from water any impurities, decayed ani-

mal matter, and purifies it. Hence, too, its value as a filter. It is of great value to the field, whether mixed with the soil or applied on the surface. It absorbs largely at common temperatures, and when heated by the sun, yields up its atmospheric treasures to assist the growth of plants and vegetables. You remember the coal beds on the old farm "down East," where, no matter what the season, or its effect upon the balance of the crop, you were sure to find well-matured corn, a large growth of plump wheat, heavy oats, or enormous melons, within the area of the coal bed. Can you recal a time, a season, when there was not a marked difference between the products of the coal-bed and the rest of the field? Had you ever investigated the subject? You remember to have planted cucumbers and melons in your garden, and to have heard some one, noted for his success in growing these luxuries early and large, say that charcoal was a capital manure. You may have tried it with success; but why were you content with the result? Why not seek for the reason? How many lose the benefit of an extended application from the want of a spirit of inquiry! We hope the Farmers' Clubs will provoke and develop INVESTIGATION.

Charcoal absorbs offensive odours. Mix it with night soil, and it makes it dry and portable. Saved and applied, this is rendered a most valuable manure. Charcoal has great preservative qualities. It will keep meat pure and sweet a long time; and who has not tried its effects in the preservation of the potato? Who ever saw a *watery* potato grow on a coal-bed? Who ever saw *small* ones grow there? We never did. Mix it with musty grain, if you have any, or impure meat, and tell us of its effects. Pack meats and vegetables in it, and they will not soon decay. It is a most unchangeable substance; hence posts, charred at the bottom, do not decay as soon as otherwise when set in the ground. Liquids passed through it lose their colouring and bitter or astringent flavour. Sugar refiners decolourize their brown syrups with its assistance.

Thus, while we have not strictly departed from the text, we have given you some facts which may be of great value to you. We have deviated from our intended course, but our aim is to make these articles as plain, practical, and valuable as possible.

Remember that we have said, the *organic* portion of plants consists of *carbon, oxygen, hydrogen,* and *nitrogen*. Water is composed of *hydrogen* and *oxygen*. Then water feeds the plant with these two gases, Burn the plant, and these gases escape in the form of vapour, which, condensed, falls to the earth as rain. You may desire to know something of the character of these gases abstractly. *Oxygen* is heavier than the atmosphere; it is a colourless gas, has neither taste nor smell; inhaled by animals, its effects are exhilarating and exciting. We have seen it given to individuals for the purpose of exhibiting its effects upon their action. In some cases the most extraordinary movements are made. It is, of course, injurious, and were we to inhale only *oxygen*, we would soon be unable to inhale *anything*. About one-fifth of the air, one-third of the ocean, and one-half of the solid earth are *oxygen*.

We extract the following passage from one of Johnston's lectures: "But the quantity of this substance, which is stored up in the solid rocks, is still more remarkable. Nearly one-half of the weight of the solid rocks, which compose the crust of our globe, of every solid substance we see around us—of the houses in which we live, and of the stones on which we tread; of the soils which you daily cultivate, and much more than one-half of the weight of the bodies of all living animals and plants—consists of this elementary body, *oxygen*, known to us, as I have already said, only in the state of a gas. It may not appear surprising that any one elementary substance should have been formed by the Creator in such abundance as to constitute nearly one-half, by weight, of the entire crust of the globe; but it must strike you as remarkable, that this should also be the element on the presence of which all animal life depends, and as nothing less wonderful, that a substance, which we know only in the state of thin air, should, by some wonderful mechanism, be bound up and imprisoned in such vast stores in the solid mountains of the globe, be destined to pervade and refresh all nature in the form of water, and to beautify and adorn the earth in the solid parts of animals and plants. But all nature is full of similar wonders; and every step you advance in the study of the principles of the art by which you live, you will not fail to mark the united skill and bounty of the same great Contriver."

Oxygen supports combustion, and all substances which burn in the open air burn in *it* (*oxygen*) with far greater brilliancy. We have said that plants exhale *oxygen* under the influence of sunlight, and we suggest a simple experiment by which this exhalation may be made perceptible.

Let a sprig of mint be placed in a white glass globe, which is then to be filled quite full of spring water, and the mouth inverted in a tumbler of water, it is then to be placed in the direct rays of the sun, and in a short time bubbles of gas will be seen collecting in the upper part of the glass, which is nearly pure *oxygen*.

Hydrogen is fourteen times lighter than the atmosphere and sixteen times lighter than oxygen, being the lightest substance known. It is combustible, but does not support combustion. The affinity of oxygen and hydrogen is very great, yet they do not combine spontaneously. Hydrogen is colourless, and does not support life. Animals die and plants wither when introduced into it. It is not necessary to the growth of plants. United with oxygen, it becomes water or the protoxide of hydrogen. Water is an essential to the plant, but Nature has provided an ample supply. It is our province to regulate and modify this supply. Irrigation at the proper time is an immense stimulant, or, more properly, fertilizer. But our *best* soils, the most durable and reliable, require drainage, and provision for feeding the plant with *only* the amount of water needed, and disposing of the surplus. We need write no "apostrophe to water." It may be of use and abuse. It *is* both used and abused. Let us learn to use it.

Next in order of the *organic* portions of plants is *nitrogen*—one of the most important *organic* constituents of vegetable matter. It constitutes about four-fifths of atmospheric air. Animals cannot live in it alone, yet they cannot be matured without it. Plants die in it, yet it is necessary to their growth. Reference has already been made to its use to dilute the oxygen of the air, so as to render it palatable and life-giving. Its existence has been known since 1772, and it was recognized as a constituent of the atmosphere in 1775. It does not support combustion, but extinguishes all burning bodies immersed in it. It is not inflammable. It is generally supposed that plants get no nitrogen from the air. Johnston says, "Spring and rain waters absorb it, as they do oxygen, from the atmospheric air, and bear it in solution to the roots, by which it is not unlikely that it may be conveyed directly into the circulation of the plants." But plants are mainly fed by nitrogen through some of its compounds. *Ammonia* is one. It is composed of nitrogen and hydrogen. Seventeen pounds of *ammonia* contain about fourteen pounds of nitrogen and three pounds of hydrogen. It is important to the growth of the plant—one of the most important compounds. It is common—every farmer has to do with it and daily witnesses its effects, is made aware of its presence by his senses, yet scarcely heeds its value, and often regards it as a very noxious vapour which ought not to exist. But it does exist in the atmosphere everywhere where animal or vegetable matter is decaying. It is about three-fifths as heavy as atmospheric air. Our readers will recognize it as spirits of hartshorn, and it is sometimes called alkaline air, or volatile alkali. It is colourless, does not support combustion, and is inflammable. Here is another wonder for you, reader—a combination of two colourless and tasteless gases and without smell, in the proportion of 14 and 3 produces another gas that has pungent smell and a very perceptible taste. And is it not more wonderful, that it should exist, and enter so largely into all the successes and reverses of the farmer's operations, become part of his stock-in-trade, and yet create no inquiry into its properties, no curiosity as to its use or value? It is escaping yonder from that manure heap, from the liquid steaming excrements of your cattle. Here again you witness the value of absorbents to mix with animal manures. Charcoal or muck absorbs largely and should be largely used. Water absorbs ammonia over 700 and nearly 800 times its bulk of it, and is made the medium to transfer the ammonia of the atmosphere to the growing plants. Ammonia is powerful in its effect upon the plant. It promotes its luxuriance and growth. It is mainly and perhaps wholly taken up by the roots of the plant from the soil, not being inhaled by the breathing leaf as is carbonic acid.

Liebig says, "The effect of an artificial supply of ammonia as a source of nitrogen is to accelerate the growth and development of plants." And he attaches great importance to this fact, and argues that it should be taken into account in gardening —especially in kitchen gardening, and as much as possible in agriculture on a large scale, when the time occupied in the growth of plants is of importance, as it is most certainly in our latitudes. Indeed it is the most valuable fertilizer contained in farm-yard manure, and it exists to a greater extent in the liquid part than in the solid excrement. And yet farmers—the great majority of them—provide no means for conveying this important fertilizer to the plant.

The stable manure may be thrown out under the eaves of the stable, and into the street, with no absorbing mixture. The eaves of the stable have no fixtures to convey the water into a cistern for the use of the stock, but the dripping flood inundates the manure heap, and leaches away into the street ditch, to be turned perhaps by a shrewd neighbour, if one happens to live lower down a declivity, into his own fields by a furrow or five minutes' use of the spade, and irrigates *his* fields, furnishing his crops with a wealth of nutriment and stimulant—the *gold* of *your* manure. We have seen it done. We are not imagining anything. The same principle applied to commerce would ruin every man who indulged in it. Suppose the merchant should throw *gold* into the street, and depend upon the silver or currency received for profits, and to replace and replenish his stock; what would be thought of him? Does a farmer *know* these facts—know he is losing the *best* of his resources for the replenishment of his farm, and still neglect to take measures to retain them? Cannot *afford* to provide against this waste? If God had not blessed us with a land unrivalled in fertility, and had not provided in nature compensation for the consumption of plants, man, if left alone, would soon impoverish himself, and the earth would become barren and unfruitful.

Ammonia does not enter the plant by inhalation (if we may use the term) through the leaves. It is a gas, but there are few plants that do not require it to knock for admittance at the roots, and in company (solution) with water; and here again we must urge your attention to the saving the *liquid* manure of your stock, so full of nitrogen for the plant. It has been suggested to leave the stable floor open, with a muck-bed under it, to receive the leakage. Another plan is, to have a close floor, and litter the stable behind the stock with muck, sawdust, or tanbark-charcoal. And here we wish to say one word upon the use of muck as an absorbent. Ignorant once of the philosophy of composting, we helped a man, *then* considered more progressive than his neighbours, to clean out a swamp of its muck deposit—a purely vegetable substance. It was thrown around an orchard at once—at the roots of each tree. It had its effect, it is true; the trees grew marvellously. But, if instead of depositing it thus to "save handling," it had been hauled to the large shed in the barn-yard, and then mixed with the stable manure, which was evaporating, and leaching under the eaves on the south side of the barn, we would have *saved* enough by the operation to have paid the expenses and produced more wonderful effects still. Why? Because that muck was pure and (almost) unadulterated carbon—the best of

absorbents, and that is *why* we urge composting with it; it saves for the use of the plant the ammonia in the manure mixed with it. Attend then to this matter, and save the *liquid* portion of the manure in your yards and stables.

Deep ploughing has to do with the production of ammonia. It enables the roots of plants to penetrate and fill the subsoil with vegetable matter, which, by its decay in the confined atmosphere, where the access of the oxygen of the air is not easy, gives rise to the production of ammonia. When thus formed, it is chemically prepared, and enters the roots of the bearing plant to assist its growth. We said, the ammonia of the atmosphere is absorbed by rain, dews, &c., and returned to the roots; hence, the necessity of rain and dews—the latter particularly, where vegetation is rankest and growing most rapidly, requiring continual supplies of nitrogen. Who can estimate the value of a heavy body of snow during four months of the year succeeding a fruitful season? Here is matter for inquiry and reflection, fellow farmer. How wonderfully accurate is the action of God's great laws of compensation—of supply and demand!

We have hitherto been talking of the *organic* parts of plants—those parts that burn away, of which nothing visible remains after combustion. Those parts which remain in the form of ashes are called the *inorganic*—are derived by the plant from the earth, and when the plant is decayed become earth again—were obtained from the soil, and have become soil again by combustion. The inorganic parts of plants are in small proportion to the organic, and yet they are numerically greater.

Let the reader remember that carbon, oxygen, hydrogen, and nitrogen are the four kinds of matter comprising the greater and organic portions of plants; and yet the inorganic portion, though smaller, consists of nine or ten different parts. We are now to consider these. We may learn something new, and digressions will be in order if we find it for the interest of the reader to extend our science to its practical application. It involves the manure question at every point, and here we may discover, possibly, whether the rich and so-called *exhaustless* (!) virgin soil of the prairies, will need to be prostituted by the application of the *foul stuff* called barn-yard manure.

Burn a plant, a mass of weeds, a stack of wheat or other straw, reader, and how little of it is left! this you have noticed. How small in proportion to the bulk consumed, and the bulk of ashes that remain! This is the inorganic part; very seldom amounts to twelve or fifteen per cent. of the weight of the vegetable substance burned. If it be straw you have burned, the weight of the ashes will seldom exceed four or five per cent. of the weight of the straw consumed. Yet this part of the plant is as important as any other, comes from the soil and must exist in the soil, so that the plant may take up the proportions required in its structure—in its growth.

Burn a ton of straw, weigh the ashes, and you, who return nothing to your fields in the shape of manure, estimate the amount of inorganic matter you take from your farm annually, saying nothing of the ashes, or inorganic part of the grain the straw yields. How long can you continue to crop your land without impoverishing it, by this no-return process? We want you to have time to ponder upon the figures you may make, by calculating that five per cent. of every ton of wheat-straw you take from your farm is actually taken from the soil, and must be supplied in some manner, and if you are not supplying it, you are growing poorer. Let the figures tell you how fast you are growing poorer. When you have aroused yourself from the stupor of insensibility, you will be in fit mood to search into the character of these several inorganic parts of plants; for it is not regarded by moderns as "stealing trash" to steal our *purse*.

Having sufficiently pondered on the amount of inorganic matter taken from the soil in every ton of straw, and which must be replaced or the soil is constantly impoverished, let us inquire what *are* these inorganic parts? Potash is an alkali—one of the four alkalies found in the ashes of plants. It is found in most plants. Fill a barrel with wood ashes, and leach with water—the *ley* contains the potash of the ashes. The pearlash of commerce is only potash and carbonic acid, a union of the two produced by the exposure of the former to the air, and if the quantity of carbonic acid is increased, saleratus is the result.

Many of our readers, perhaps, have had experience in the manufacture of pearlash. In early days, when the heavy forests of the North and East were being cleared, it was no unusual thing for the settler to turn a penny by the rustic manufacture of this alkali into an article of commerce. We have not unfrequently found it in the large open fire-places of the borderers, and secured it for the good dame's use, by using the "poker" among the ashes.

Plants, trees, and animals require potash in their construction. Hence it must be found in the soil, and supplied if cropping has diminished the supply.

The importance of this supply in the soil will be seen when the reader understands that every acre of wheat absorbs over thirty-two pounds of potash from the soil, barley over sixty-eight pounds, red clover over one hundred and forty-four pounds, and other common crops in different proportions. How is it to be supplied? Remember this is only *one* of the inorganic parts that you exhaust in this quantity from each acre of soil grown in wheat, barley, clover, &c., annually. Is it not a great exhausting process? Is there no necessity for supplying this food, of ploughing deeper, of manuring more? If your soil is wanting lime, ashes may be substituted. But this supply of inorganic matter in some form *must not* be withheld from your farm. It is a great study to learn how to economically supply it—of great importance you should learn. Potash may be used on sandy soils with good effect, and is a valuable application as a top-dressing for young plants, *for insects do not like it.*

Soda is another alkali found in the ashes of plants, and is not unlike potash in its office in the construction of the plant. Common salt contains it; hence the application of this *thistle-killer*—salt

—to the soil furnishes soda for the plant, and is often the best application that can be made; this, however, is a disputed question. In passing, we wish to say that *brine* is a great vermin antidote, and if carefully applied to the soil and to the compost heap will do quite as much good as harm. Caustic soda, produced by boiling the common carbonate of soda with quicklime, is dangerous to the vegetable. Common salt and lime mixed together and used in composting is very valuable as a supply of soda, for the plant is thus obtained.

Lime. The reader may perhaps consider himself posed in reference to this alkali. But its importance to the plant is oftener under than over-estimated, and it is often blindly applied, and often not applied at all when it should be. It sweetens the soil, decomposes vegetable matter, and as a sulphate is a good absorbent of the different gases. But the importance of this inorganic part of the plant to the agriculturist must be the subject of another chapter.

Phosphoric acid, although combining with any of the alkalies, is most important when compounded with lime. It is composed of phosphorus and oxygen. The white smoke of a match when it is ignited is phosphoric acid, created by the union of the phosphorus on the end of the match with the oxygen of the atmosphere. Its importance will be understood when we tell you it forms nearly one-half of the ashes of wheat, rye, oats, buckwheat, barley, peas, beans, &c., and enters largely in the perfection of vegetables and animals; and yet it is found in limited quantities in most soils, particularly those where cultivation has not been remunerative—where the whole system has been to get all possible, and pay nothing to the soil for its harvests.

This acid does not exist in nature in a free state, and hence, isolated, does not affect vegetation; but as we have said, it unites with the alkalies and forms phosphates, which *are* essential to the growth of the plant, without which, perfection in the development of grains and roots cannot be obtained. It is solid and colourless, soluble in water, sour, corrodes and destroys animal and vegetable substances. It is found in combination in all plants, hence its necessity to them as an article of food; and yet it must be diluted or mixed, hence the double importance of the different alkalies as fertilizers.

The intelligent, thoughtful reader will not wonder at the constant diminution of fertility in cultivated—aye, *skinned* soils. What debts would some farmers have to pay, if the earth were to make the demand to each one, "Pay that thou owest," in the shape of inorganic matter taken from their farms, and never returned! It is estimated that in every hundred bushels of wheat sold, there are removed permanently from the soil on which it grew, sixty pounds of phosphoric acid! and that for each cow kept on a pasture throughout the summer, there are carried off in veal, butter, and cheese, not less than fifty pounds of phosphate of lime, of which perhaps nearly or quite one-fourth is phosphoric acid.

Warring says well, "This would be *one thousand pounds* for twenty cows; and it shows clearly why old dairy pastures become so exhausted of this substance, that they will no longer produce those nutritious gases which are favourable to butter and cheese making." We may as well quote the next paragraph, and endorse it, viz.: "That this removal of the most valuable constituent of the soil has been the cause of more exhaustion of farms, and more emigration in search of fertile districts, than any other single effect of injudicious farming, is a fact which multiplied instances most clearly prove."

He instances the once world-renowned wheat-producing Genesee Valley. It is well known that its fame as a wheat country does not belong to the present. And yet how many of the Western farmers, or Eastern either, can tell to-day what phosphoric acid is, or that such matter exists? They have as little idea of it, its importance to the soil, its character, and how it is found, as they have of the size of brain of the inhabitants of the planet Saturn; and how willing to let their children grow up in the same sort of ignorance, and with the same indifference to what grows, and what causes it to grow! They want them to read, write, and cipher—it was the *schooling* they had, and they get along!

O fellow farmer, insist upon that boy and girl of yours knowing something of this earth, beside its shape, diameter, and circumference, and who circumnavigated it. Require that the teacher should at least know something of plants this summer; be capable of teaching your child the beauties, peculiarities, and office of plants and flowers—in short, insist he must know something of botany. But we have left *the* acid, though we may have exhibited some acidity; if so, we cannot help it, for we feel very much like scolding at the indifference manifest to these important departments of education.

Phosphoric acid is indispensable then; it must exist in some form in the land. If you want intelligent animals, they must be fed with plants containing phosphoric acid, for phosphorus is contained in and is necessary to the health of the brain. We have said enough perhaps to set you thinking, to prove the importance of this acid in agriculture. In combination with alkalies we shall have more to say of it hereafter.—Emery's Journal of Agriculture.

AUXILIARY MANURES.

The farmers of this country have become so much accustomed to the use of guano, superphosphate of lime, and other light manures, that they would find themselves in a difficult position for a time if they were called upon to do without them. There is nothing, however, at present to indicate that they will be brought into such a position. These manures are offered in great abundance. The stores of Peruvian guano in this country are double what they were last year; and great efforts have been made by importers and manufacturers to insure abundant supplies of phosphatic manures.

But the price of these auxiliary manures is now so high in comparison with the value of farm produce, that farmers are dubious about applying them as freely as in bygone seasons.

The question as to the profitable application of guano at its present price, as a top-dressing for the cereal crops, does not admit of a general answer. It depends on the condition of the land, and other circumstances. On rich land the extra manure may cause the crop to fall down, if the season be wet; and the quality of the grain may be depreciated without the quantity being increased: but in the case of land that is well cleansed and in a middling state of fertility, we believe that it may still be applied with a fair chance of profit. Four additional bushels of wheat or eight of oats may reasonably be expected from each cwt. of guano. This quantity of grain, with the fodder, may be worth from twenty to twenty-five shillings; and as the top-dressing, including labour, does not cost more than fifteen shillings, the profit looks respectable on paper. It seems high enough to cover the climatic uncertainties, which the farmer is taught by experience not to overlook in his calculations. And the additional quantities of grain and fodder do not show the entire profit that results from the use of the guano. In the upland districts, two cwt. of guano per acre will make the oat crop eight or ten days earlier, and this may lead to a better harvested, as well as a better filled and more productive crop. There is another marked advantage in the more vigorous growth of ryegrass and clover among wheat or oats which have been top-dressed. On heavy land a free-growing clover plant may soon get beyond the risk of serious injury by slugs, when a weakly plant would be destroyed.

There have been loud complaints against the Peruvian government and their agents, because they have drawn up the price of guano to the highest rate at which they can command a sale. These complaints can be of no avail, and it is futile to indulge in them. The Peruvian government have virtually a monopoly; and in exacting the highest price which they can freely obtain, they are merely doing what other people would do in similar circumstances. If the price of grain continue to have a downward tendency the price of guano must be lowered also, as the point may soon be reached at which there can be little chance of profit to the farmer from using it. But it is lost labour to assail the monopolists, as some people do, by advising farmers to abstain from purchasing guano, as long as they expect to derive profit from its use.

One good result has followed the high price of Peruvian guano. A stimulus has been given to the manufacture of portable manures, and the attention of many intelligent farmers has been directed to experimental investigations as to their value compared with guano. The manures that are manufactured for top-dressing the cereal crops are mainly nitrogenous and phosphatic compounds. When these elements are awanting—as in the case of the Economical Manure, analyzed by Dr. Anderson—the compound is simply worthless. Mr. Townsend, Glasgow, Mr. Weir, Ayr, and other respectable manufacturers, sell by a guaranteed analysis; and we think that farmers would act wisely in giving their corn manures a trial.

A very considerable quantity of superphosphate of lime was used in Ayrshire last season as a top-dressing for wheat and oats, and as far as we can learn the results have been satisfactory. It is right to remember, however, that the high temperature of the summer of 1857 was very much in favour of superphosphate. The experience of a cold, moist season would be less favourable.

Mr. Richmond made some interesting experiments last year, on the farm of Burnton, near Dalrymple, for the purpose of testing the value of superphosphate as a corn manure, when combined with nitrogenous manures in various proportions. The manures were carefully weighed and mixed, and sown each on a single ridge to a certain number of yards from the end. The crop dressed with each manure could thus be easily compared with the crop on the remainder of the same ridge which got no top-dressing whatever. An equal money value was applied to each of the lots. The manures were harrowed in with the seed about the end of February. In making the experiments, Mr. Richmond merely intended to examine the crop carefully during its growth, and to form an opinion from observation. If experiments are to be followed to the barn floor, and brought to the final test of weight and measure, they are not worthy of much reliance unless they have been made on a pretty large scale, and the work, from first to last, has been conducted with care and precision. But to the practised eye of the observant farmer, a small experiment may be valuable if he have the opportunity of seeing the crop during its growth.

Mr. Richmond's experiments seemed to point unmistakably to the propriety of putting a considerable proportion of phosphate into manures for wheat. The crops at Burnton, as at Craigie, refuse to admit to the Rothamsted axiom—"Ammonia for corn, phosphorus for turnips." It is plain enough that in Ayrshire both crops are benefited by both manures.

In the experiments at Burnton, equal weights of sulphate of ammonia and superphosphate gave a better crop than two parts sulphate and one part superphosphate, while both lots were decidedly superior to sulphate alone or superphosphate alone. Peruvian guano alone gave a good crop; but equal weights of guano and superphosphate were about as good, and two parts guano and one part superphosphate were superior to either. Again, equal weights of muriate of ammonia and superphosphate were appreciably superior to two parts of muriate and one part of superphosphate, and both were very much superior to muriate alone or superphosphate alone. The lot dressed with equal weights of muriate and superphosphate was the best of the whole. Equal weights of sulphate and superphosphate gave the second best, and two parts guano and one part superphosphate the third best crop. When we made our inspection and took notes in August, these lots, at the termination of the top-dressing, stood up like the step of a stair above the wheat that had not been top-dressed. The wheat

dressed with superphosphate alone had less straw than any of the lots which were dressed with ammoniacal manure, but it was obviously more growthy than the wheat alongside, which got no top-dressing; and it was firmer of the straw and earlier than any of the lots. The experiments were made on a thin heavy soil, which might have been thought favourable for ammoniacal manures. The turnip crop of the previous year was grown on farm-yard manure and superphosphate of lime.

These experiments show that an equal money value of sulphate or muriate of ammonia and superphosphate of lime, gave a better return last year than Peruvian guano, as top-dressing for wheat. They also indicate that muriate of ammonia was the cheapest source of ammonia to the farmer. But it is perfectly possible that similar experiments may give different results this season, as the summer may not be so favourable as the last for superphosphate. Such experiments should be more frequently made. When observation during the period of growth is afterwards either corrected or strengthened by weighing and measuring in the barn, the experiments of course are more satisfactory; but a very considerable amount of labour is required to do this as it ought to be done. An opportunity, however, of observing the crop during the season of growth may sometimes convey useful lessons to the farmer; and a little attention may enable anyone to make a few simple experiments for this purpose.—Ayr Advertiser.

THE NEGLECT OF AGRICULTURE THE FORERUNNER OF NATIONAL DECAY.

SIR,—We read of the neglect of agriculture being the downfall of the Roman Empire. When Julius Cæsar conquered all the then-known world, he made every country, as he conquered it, pay a tribute in corn instead of gold and silver; which soon ruined the Roman farmers, by having their markets glutted with corn the produce of other countries instead of their own.

It is plain, corn grown in England is doubly advantageous, because it is produced by English labour instead of foreign labour. The *Mark-lane Express* is doing wonders by opening the eyes of the foreign farmers, by showing them weekly the wonderful improvements in our agricultural implements. Of course common sense says that a vast deal of our agricultural machinery will find its way into all parts of the globe to cultivate their land with, which will cause our English markets to be glutted with foreign corn produced by foreign labour. It is expedient to give the British farmer a tenant-right (*alias* equity or justice between landlord and tenant), or the foreigners with our English-made implements in husbandry upon their maiden lands—the foreigners, who pay light rents and taxes, in a few years will bring the English farmers to the same position as that in which the Roman farmers were. No country can be great that is poor in agriculture. Upon estimating the value of the stock and crops in England, it will be found that ours is the richest country, per acre, on the face of the earth.

SAMUEL ARNSBY,

Mill Field, Peterborough, April 8,

STOCKBRIDGE ANNUAL SHEEP AND CATTLE SHOW.

The premiums given this year were nearly double as compared with former years, and, as a natural consequence, the competition was more keen. The stock exhibited, particularly of sheep, was of that usual good quality which distinguishes the flocks and homesteads of Hampshire and Wiltshire. The principal exhibitors were the Right Hon. the Earl of Portsmouth; Mr. Moore, Littlecott; Mr. Bennett, Chilmark; Mr. Edney, Whitchurch; Mr. Olding, Amesbury, and others. Mr. Pain, of Houghton, exhibited a pen of teg rams as extra stock, which was highly commended by the judges; a pen of ram lambs, eleven weeks old, shown by Mr. Moore, of Littlecott, were also much admired.

For the best Hampshire Down Ram, a silver cup, value 3*l.* 3s.—Mr. Bennett, Chilmark.

For the best Hampshire Down four-tooth Ram, a silver cup, value 3*l.* 3s.—The Earl of Portsmouth.

For the best Hampshire Down Teg Ram, a silver cup, value 5*l.* 5s —Mr. French, Longstock.

For the second best ditto, a prize of 1*l.*—Mr. Edney, Whitchurch.

For the best Ram of any kind, breed, or age, the criterion of merit to be the possession of general qualities necessary to form the most useful and profitable sheep, a prize of 2*l.*—Mr. John Moore, Littlecott.

For the best Hampshire Down four-tooth Ram, a prize of 2*l.*—Mr. Olding, Amesbury.

For the best Hampshire Down Teg Ram, a silver cup, value 5*l.* 5s —Mr. F. Baily, Candover.

For the second best ditto, a prize of 1*l.*—Mr. Olding, Amesbury.

For the best Hampshire Down Ewe Tegs, bred by the exhibitor, in the proportion of 2 to every 100 Ewes kept and put to tup in the preceding year, to be kept with the flock up to the day of exhibition, a silver cup, value 3*l.* 3s.—Mr. Bennett, Chilmark.

For the best Hampshire Down Ewes in milk, in the proportion of 2 to every 100 Ewes kept and put to tup in the preceding year, to be kept with the flock up to the day of exhibition, a silver cup, value 3*l.* 3s.—Mr. Lywood, Houghton.

For the best Hampshire Down Ram Lambs, in the proportion of 1 Lamb to every 100 Ewes kept and put to tup in the preceding year, bred by the exhibitor, a silver cup, value 3*l.* 3s.—The Earl of Portsmouth.

Mr. Edney's Ram Lambs in this class highly commended.

For the best Ram of any age, the exhibitor not saving more than 10 ram lambs, a silver cup (given by Thos. Baring, Esq.), value 3*l.* 3s.—Mr. Chamberlayne, Up-Somborne.

For the second best ditto, a prize (given by T. Baring, Esq.) of 2*l.*—Mr. Ayles, Michaelmarsh.

For the ten best Hampshire Down Ewe Tegs, bred by the exhibitor, to have been kept with the flock up to the day of exhibition, the exhibitor not saving more than ten ram lambs, a silver cup (given by Mr. John Day), value 5*l.* 5s.—Mr. Elderfield, Houghton.

For the ten best Hampshire Down Ewes, in milk, to be kept with the flock up to the day of exhibition, the exhibitor not saving more than ten ram lambs, a prize of 2*l.* 2s.—Mr. French, Longstock.

For the best Cow, in milk, a cream jug (given by Mr. John Day), value 3*l.* 3s.—Mr. Foster, Kingsomborne.

For the second best ditto, a prize (given by Mr. Day) of 2*l.*—Mr. W. Pothecary, Wallop.

For the best Heifer, in milk, not exceeding three years old, a prize of 2*l.*—Mr. Flower, Longstock.

For the best Bull, a prize of 2*l.*—Mr. C. Fielder, Sparsholt.

For the best fat Calf, under 12 weeks old, bred by the exhibitor, a prize of 1*l.*—Mr. C. Fielder, Sparsholt.

For the best Boar, a prize of 2*l.*—The Earl of Portsmouth.

For the second best ditto, a prize of 1*l.*—The Earl of Portsmouth.

For the best Breeding Sow, a prize of 2*l.*—The Earl of Portsmouth.

For the second best ditto, a prize of 1*l.*—The Earl of Portsmouth.

For the best Cart Stallion, prize of 2*l.*—Mr. Ayles, Michaelmarsh.

For the best Cart Mare, in work, prize of 3*l.*—The Earl of Uxbridge.

For the second best ditto, a prize of 1*l.*—Mr. French, Longstock.

For the best Cart Colt or Filly, foaled since the year 1854, bred by exhibitor, a prize (given by Thos. Baring, Esq.) of 2*l.* 2s.—Mr. T. Attwood, Stockbridge.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A WEEKLY COUNCIL was held on Wednesday, the 28th of April: present, Lord Berners, President, in the chair; Marquis of Downshire, Lord Feversham, Hon. A. Leslie Melville, Hon. Colonel A. Nelson Hood, Hon. William George Cavendish, Sir John V. B. Johnstone, Bart., M.P., Mr. Dyke Acland, Mr. Astbury, Mr. Raymond Barker, Mr. Hodgson Barrow, M.P., Dr. John Bright, Mr. J. S. Budd, Mr. Caldwell, Colonel Challoner, Mr. Corbet, Dr. Daubeny, Mr. Davey, M.P., Mr. Druce, Mr. Joseph Druce, Mr. Fison, Mr. Brandreth Gibbs, Dr. Gilbert, Rev. L. Vernon Harcourt, Professor Henfrey, Mr. Fisher Hobbs, Mr. Wren Hoskyns, Mr. Richard Jennings, Mr. Langston, M.P., Mr. Lawrence, Mr. Thomas Lee, Mr. John Lloyd, Mr. Majendie, Mr. Milward, Professor Nesbit, Mr. Pain, Mr. David Pugh, M.P., Mr. Robinson, Mr. Thomas Scott, Mr. Slaney, M.P., Rev. William Smyth, Mr. W. C. Spooner, Mr. Banks Stanhope, M.P., Colonel Towneley, Mr. Vyner, Mr. Burch Western, Mr. Wilshere, and Mr. Joseph Yorke.

Communications were received from Mr. Duckham, on the desirableness of the Society's Country Meeting for 1862 being held at Hereford, and of that county being represented in the Council on the nomination of members resident within it; and from Mr. W. G. Field, of Notting-hill, on the establishment of a permanent depôt, in the neighbourhood of London, for the exhibition of live stock and implements.

LECTURE.—Dr. Voelcker, consulting chemist to the Society, then delivered before the members the following lecture, "On Agricultural Chemistry, in its Relation to the Cultivation of Root Crops," Lord Berners, President, in the Chair:

MY LORD, AND GENTLEMEN,—If there ever was a time when a knowledge of science was more useful to the agriculturist than at another, it is the present. If there be any country in which a knowledge of science is of more direct use than in another, it is England. There are various circumstances which conspire to account for this. If we look to the agriculture of the Continent or of the Colonies, we shall find that there is little scope left to those farmers who are possessed of theoretical knowledge of those sciences that apply more especially to agriculture. It is different in England. English agriculture, as we all know, is perhaps the first agriculture of the world. Certainly, in no country is agriculture in such an advanced state as in England; and it is easy to demonstrate, if it were necessary, that, in countries in which agriculture has reached a high state of perfection, resources are open to the cultivators of the soil, which in less favourable conditions are totally inapplicable. England certainly has the advantage of having the landed property in large estates, for the most part: it is blessed with intelligent proprietors, and with large tenant-farmers, who, in the present state of agriculture, find it impossible to overlook altogether the resources which are offered to the agriculturist by science. But it is foreign to my object to dwell upon a comparison between English and continental agriculture. I allude to the subject here, in order briefly to remark upon the necessity which I believe exists at the present time of a more extensive cultivation of the study of sciences on the part of the rising generation of agriculturists. In no country is this more desirable than in England. We require better instruction among every class of men interested in agriculture. The landlord may derive great advantage, I am convinced, if he have a knowledge of the rudiments of science, for it will enable him to distinguish at once between the suggestions of the true man of science, and those which emanate from men that are neither practical nor scientific, which are so much calculated to throw discredit upon all scientific investigations, and thus retard the application of science to agriculture. And the large tenant-farmer is brought into more direct contact with scientific matters, since many improvements, which are only practical on large estates, are based on chemical principles. All farmers who manage farms of any extent are compelled to use artificial manures: and here we find that those who have not a clear appreciation of the circumstances which regulate the value of artificial manures, are entirely at the mercy of men who designedly seek to dispose of substances that do not deserve the name of manures. This could not be possible if every tenant-farmer had a knowledge of the first principles of chemical science. At the same time it is quite true that everybody does not stand in the same need of acquiring a knowledge of chemistry. It would be ridiculous, I think, to teach the agricultural labourer agricultural chemistry; nor would it be desirable that the small tenant-farmer should occupy his time in acquiring chemical knowledge. He requires to be eminently a practical man, and to be satisfied with simple tastes, and he will realize little benefit if he employ his time in the study of a knowledge which, in his position of life, will be of comparatively little practical utility, since he finds no scope for the exercise of such superior knowledge. But the question is quite different with the landed proprietor and the tenant-farmer who manages even a moderately-sized farm. There have at all times been excellent practical men who do not pretend, and never have pretended, to any knowledge of chemistry; and though there may be some who speak disparagingly of chemical science even at the present time, yet I believe the most intelligent farmers have a sort of intuitive feeling that they might have spared themselves a great deal of labour in acquiring that practical knowledge which so eminently distinguishes them at the present time, if they had possessed those facilities which are now offered to the rising generation in acquiring a knowledge of science, more especially chemical science. They are, therefore, anxious to secure to their sons and those dependent upon them the means of not only acquiring rapidly the experience which by a long process they have themselves accumulated, but to extend that experience; and I believe there is no better mode of rapidly acquiring practical experience and extending our knowledge of practical matters than a study of the principles on which agriculture is founded, more especially chemical principles. Science is eminently calculated to get experience; for what is science after all, but the systematic arrangement of well-authenticated facts? At an early stage of almost any practical occupation there is no scope for the exercise of scientific applications; the facts are

limited, and they can be easily recollected. But when the number of facts accumulates to an extraordinary extent, none but those blessed with an exceedingly good memory can gain practical information. We want, then, some grand principles which shall enable us to recollect facts. Neither chemistry nor any other branch of science ought to be the direct guide to the agriculturist. It should never put itself in the position of telling a practical man what he has to do; but it ought to explain the experience of farmers and facilitate the understanding of practical matters to the rising generation; for there would be no progress whatever possible if each generation had always to learn again the same practical matters, a knowledge of which their forefathers had gained. They require to have some grand principle, to lay hold at once of those numerous practical facts, and then they are in a position to extend previous experience. Hence, I believe, at the present time especially, science is eminently calculated to be of great utility to the rising generation. The most successful farmers in all ages have always been men in advance of their times. Our most excellent farmers of the present time have been distinguished in their manhood for something for which they were ridiculed at one period of their life. When they had to contend against popular prejudices, chemistry as a science was altogether unknown. In all probability if chemical science had been applied to agriculture as it has since been, they would have been "meddling" with it, as the phrase goes; but they "meddled" with some new plough or some new implement for which they were ridiculed, and at first it would seem properly, because they failed in their attempts: but they were men of character, perseverance, and intelligence; they did not abandon a new process because it was ridiculed, they did not cast aside a new instrument because it did not at once work well; they put their shoulders to the work, applied their intelligence, brought out the new implement, or, by making use of their previous experience, introduced a new process, which was gradually accepted, since it was found to answer in a great many instances, and the circumstances under which it would be useful to the farmer were clearly recognised. Chemical science in its relation to agriculture had to pass through all the different stages which a new-born babe or child has to pass through during the first years of existence. We have seen the joy with which the new light of chemistry in its relation to agriculture, as it has been called, has been greeted. Those who have welcomed it with the greatest joy have, it cannot be denied, too much petted, so to say, those scientific men who applied themselves to the investigation of chemical subjects in relation to agriculture: and it has very soon appeared that, like petted children, many of the professors of chemical science over-estimated their own powers, and instead of explaining the experience of practical men, they set themselves up as guides to the farmers; in short, they over-estimated the powers of the new science, and, in consequence, stumbled. It cannot be surprising that practical men should have laughed, at various times, at the extravagant expectations which were held out by scientific men themselves. It was very soon found out that, as yet, chemical science had nothing but promises to offer. It was then that chemistry had to pass through many troubles; it received a rough handling; and it is surprising that amidst the petting on the one hand, and the rough handling on the other, it did not die a natural death. But it is fortunate that, at all times, there are intelligent and liberal-minded men who, though they may regret the extravagances of the young, yet recognise the talent that may be but a spark, but which requires only to be directed in the proper channel to become mighty means for practical and social good. It reflects great credit on that immortal man Mr. Pusey to have foreseen, with all his practical tact and clear intelligence, the important advantages which chemistry is capable of securing at one time or the other, and who was fortunate enough to secure the services of my predecessor in office. The services rendered by Professor Way to this Society, and to agricultural society at large, are too well known to require comment from me on this occasion. His works will be read and appreciated by successive generations; they have a permanent value, and belong to the choicest contributions of your Journal. In alluding to your Journal, my Lord, excuse my making one remark, which may, perhaps, appear out of place. I was surprised the other day to hear that the Journal was in danger of losing its standing as the first leading agricultural publication of the day; that the former volumes were much more practical than those issued in later years. I was surprised to hear these remarks, because I have heard remarks in the opposite direction from many agriculturists with whom I have conversed. There will always be differences of opinion; but it is worthy of remark that the most talented, rising young farmers generally speak very favourably of the contributions to the later volumes of the Royal Agricultural Society's Journal; whilst observations of an opposite tendency are chiefly made by men who were of full age, if I may use the expression, when chemistry, as a science, was altogether unknown. Be this as it may, it is clear that a different mode of thought and expression pervades the productions emanating from the younger agricultural writers, which proves, I think, that the rising intelligent farmer is no longer satisfied with having simple direction in practical matters—is not simply satisfied with being told "You must do this or that," unless he is told at the same time the reason for this recommendation. And I believe that it is equally true that frequently no satisfactory explanation can be given of practical farming matters without using scientific language, however simple it may be. And, lastly, I would observe, with respect to this subject, that many of the most valuable contributions will remain a dead letter to those who have not studied the rudiments of science. In short, a knowledge of the rudiments of science, more especially of chemistry, is necessary to all who would successfully compete with the future rising generation; and if they neglect the opportunities which are now afforded to them in acquiring chemical knowledge, and a general knowledge of the principles of science, they must be content to forego the enjoyments and benefits which are peculiar to a highly-civilised country like England, and must be content to try their hands in clearing an habitable spot in the back-woods of Canada or North America, or to live, or rather vegetate, in one of our colonies. Agricultural chemistry in its application to farming is altogether a new science; and hitherto it has been, like every new knowledge, too vague and too general in its doctrines as well as in its researches. What is required at the present time is experiments made for a special purpose researches carried on in the field as well as in the laboratory. We have need of the joint labours of practical men and men of science. There are multitudes of subjects which can only be properly investigated if the man of science heartily joins with the practical man, working cheerfully together each in his own department. Nearer approach between agriculture and science, in short, is what is required at the present time. A general knowledge of the principles of farming, however useful to the practical farmer, never will help him to grow a large crop of turnips: he must have special training in practical matters in order to be a successful farmer. So it is with chemical knowledge. Men may have excellent general chemical knowledge, but if they have not special chemical knowledge in rela-

tion to farming, their labours will be of little direct utility to the agriculturist. We understand in England better than in any other country the division of labour, and this circumstance is highly favourable to the development of agricultural chemistry, for greater opportunities are offered than in any other country to men trained in scientific matters to apply their scientific knowledge to special purposes. I might take up any subject to illustrate the intimate connection of scientific labours with practical matters; but I believe there is none better calculated to show more the direct bearing of chemistry upon agriculture than the cultivation of root crops. In cultivating root crops the farmer is directly thrown in contact with chemistry, for few farmers at the present time can produce sufficient natural manure to satisfy their expectations of growing large crops of roots, and hence they are compelled to employ artificial manures. From the first period when the seed is put in the ground, or the soil itself is cultivated, to the very last moment when the roots are consumed on the farm, the farmer meets with many matters in which a knowledge of chemistry is extremely useful to him. Take, for instance, the mechanical cultivation of the soil. He is at once shown the reason why it is of the utmost importance to work the land properly, to subdivide it, to cultivate it deep. By this mechanical means he liberates mineral food for the use of root crops, which are specially benefited by readily available mineral food; for, like all quick-growing plants, roots require their food to be prepared before-hand. Hence, if on stiff lands you neglect the mechanical preparation of the soil, you have not a sufficient amount of available food to satisfy the immediate wants of the growing root crop. Then again, in putting the seed into the ground, the intelligent agriculturist is reminded of various purely chemical matters; and the question occurs to him, "Can I hasten the germination of my seed by the application of certain salts, or by soaking it in certain dilute acids? or can I use any other chemical preparation to make the seed germinate, and bring up the young plant more rapidly?" But in no time in the cultivation of root crops is a knowledge of chemistry of greater utility than when the farmer has to decide what manuring substances he ought to apply in order to obtain a good crop of mangolds, swedes, or turnips. Perhaps he is told he ought to use super-phosphate, or guano, or a mixture of the two, or a special turnip manure: how is he to decide what super-phosphate he is to select, if he does not understand the character of the ingredients that enter into the composition of super-phosphates or guano? and how can he understand the chemical composition of super-phosphates if he does not understand chemical terms? If he look at an analysis like that before me, he may glance over it; but if he does not understand what the meaning of the term "soluble phosphate," for instance, is, he runs the risk of selecting an inefficient manure, which he buys simply because an analysis has been offered him. It never enters his mind that a man who has to sell a very inferior article would have it analyzed, and to issue the analysis with all the impurities which the manure contains; hence, he is satisfied with simply seeing the analysis. It is, therefore, of great utility to understand the chemical terms for the substances that enter into the composition of those manures which are most frequently used for agricultural purposes. But, in the first place, it is of great importance to be able to select those manures which are best adapted to the cultivation of roots. Let us take, for example, the cultivation of swedes. We hear constant discussions as to whether guano is better than super-phosphate, or whether a mixture of guano and super-phosphate should be used; and these discussions are never brought to a successful issue, simply because we require to ascertain, first, whether ammoniacal matters can be dispensed with in the cultivation of root crops, or not, and what the conditions are under which we can dispense with ammonia, a very expensive manuring constituent. The question of the superiority of guano or super-phosphate mainly hinges upon this: "Can I dispense with the expensive ammonia, and yet grow a good crop of roots?" Now, I have no hesitation in saying that there are many instances in which roots may be grown with great advantage without the direct application of ammoniacal manures; and that in all these instances a great deal of the most useful constituent of guano is, comparatively speaking, lost, and that guano is therefore to a great extent misapplied. Now, before I allude to some experiments which I made some years ago, and which I hope the Society will enable me to carry on for years to come (for it is only by a succession of experiments that truth is gradually established), I would simply mention the practical experience of many farmers who have found that a mixture of super-phosphate and guano has answered much better than guano alone; and likewise the fact that inferior guanos, rich in phosphates, but, comparatively speaking, poor in ammonia, have answered better, practically, than the best Peruvian guano. I might also appeal to the experience of many farmers who apply nothing else in the cultivation of their roots but super-phosphates prepared from bone-ash alone. Moreover, it is the tendency of the present time to produce super-phosphates comparatively poor in nitrogen. It is not likely that an intelligent class of men like the artificial manure makers would shorten the supply of ammonia in artificial manures if they did not find that it answered their purpose. If they could satisfy their customers without going to the expense of using much ammonia in the composition of artificial manure, they were evidently the gainers. I would not, however, have you to understand that I think that ammonia can be dispensed with even in the cultivation of root crops. I know that it cannot be. There are many soils on which the very cheapest manure that you can possibly use is guano. There are many soils in which ammoniacal matters are beneficial to the root crops; but the instances are far more numerous in which phosphates are more beneficial. With a view of throwing some light on the action of ammonia on root crops, more especially on turnips, I some years ago instituted some experiments which were purposely made on extremely poor land—very thin and exhausted land. They were not made with a view of ascertaining how large a crop of turnips I could obtain by the application of certain mixed manures, but more especially for the purpose of ascertaining whether on our soils and the soils in our neighbourhood we could dispense with the use of ammonia or not, and what manuring constituents were likely to be of the greatest benefit to the root crops. I used for this purpose several simple salts—like sulphate of ammonia, sulphate of potash, sulphate of soda, sulphate of lime—besides phosphate in a soluble and most available condition, alone, and mixed with ammonia. That the soil on which the experiment was carried on was extremely poor is shown by the result embodied in the diagram to which I direct your attention. The natural produce of the land in one part was about 3 tons, and in another part 2 tons 11 cwts. 19 lbs. That is the difference between the middle of the field and the outside; it is too small to be taken into account. And allow me to observe that I think that all differences in practical experiments amounting to no more than half a ton ought to be dismissed altogether as accounted for by natural variations in the soil, or by accident. You should not dwell upon these minute differences, and draw nice distinctions as to the action of different manuring matters. And

permit me to throw out a hint for all who take an interest in practical experiments, and that is, to test the natural capabilities of the soil by making two experiments with nothing. You will observe that in these experiments sulphate of ammonia had no effect upon the root crop at all; if anything it diminished the produce. I was not a little surprised in obtaining this result, expecting as I did that the ammonia would force on the crop. We are in the habit of connecting the rapid starting of the crop with the presence of ammonia in the soil on the manure: we call ammonia a forcing element, but certainly in relation to the young swede it cannot be so called; it does not force on the seed, but rather retards the germination. In all these experiments I find that the least you do artificially by using various salts or guano, or even super-phosphates, the more rapidly the seed germinates; and hence it follows likewise that it is desirable not to put the seed in direct contact with the artificial manure, and, if possible, to apply farm-yard manure in the autumn; at least, this should be done in heavy land; the manure then has time to diffuse itself throughout the soil, and you do not get those injurious effects which are produced when you put the seed into a part of the soil which is too highly manured, which it necessarily will be if the manure has not had time to diffuse itself throughout it. And even with the application of artificial manures I cannot help thinking that in many instances it would be more useful to apply them with the broad-cast distributor than drilling immediately with the seed. At least I have heard many excellent practical farmers expressing themselves to this effect. I merely throw this out as a matter of report made to me, and not as advocating either the one or the other method of applying artificial manure. Guano more especially retards germination of turnip seeds, and I have no doubt in my own mind that it is the large amount of ammonia in guano that produces this undesirable effect; but I have not found in my experiments that super-phosphates hasten the germination of the seed. When the young plant is up, then readily available food in the soil is of the greatest utility, and the turnip grows rapidly. Hence there is some truth in the observation that super-phosphate pushes on the turnip crop, bringing it out of the reach of the turnip-fly; but it does not facilitate the rapid germination of the seed: it has rather a contrary effect. It has been questioned by high authority whether the effect of super-phosphate on root crops might not be due as much to the sulphuric acid as to the phosphoric acid; but you have here a direct experiment which proves better than any theoretical reasons the erroneousness of this view. With super-phosphate alone, made from purely mineral phosphate, the natural produce of the land, amounting to three tons on the average has been nearly trebled. In all experiments, in short, where phosphate has been used, the crop has very much increased; whereas when gypsum has been applied, no benefit has resulted from the application. I may add that last year I made another series of experiments in which the same result has been brought out:

With nothing the produce was ..	6 tons	11 cwt.	2 qrs.
With gypsum	6	13	3
Whereas super-phosphate without ammonia produced	10	17	0

In all these experiments neither sulphuric acid applied in the shape of gypsum nor ammonia has done any good. In an experiment made on another part of the farm last year, I again found that ammonia was of no utility. Thus sulphate of ammonia applied to a field which naturally yielded 6 tons 11 cwt., produced 5 tons 6 cwt. 21lbs.—to some extent diminishing the produce. It is certain that in these cases ammoniacal manures, like guano or compound turnip manures, are to a great extent misapplied, because the farmer loses the immediate effect of the most expensive constituent of the manure. But I am acquainted with other experiments in which guano is of very great utility, and produces a better effect than purely mineral phosphatic manures. It remains to be seen what the exact circumstances are, under which we can dispense with ammoniacal manures, and also under what circumstances we can dispense with phosphatic manures for the cultivation of root crops: for I think that there are instances in which even superphosphate is misapplied—in which superphosphate and phosphatic manures as applied to root crops are of little practical utility. I should be extremely gratified if any instances of practical failures with superphosphate were reported to me, and portions of soil reserved for further examination, if such should be found necessary. The question whether we can dispense with the artificial supply of phosphates is a very important one—next in importance to the one upon which I have just now dwelt—which awaits its practical solution, and will no doubt find it when we continue to institute experiments with a distinct object in view, without reference to any immediate result made with the view of explaining existing practices: it is only then that we can arrive at legitimate conclusions. Experiments are frequently made very much in the manner in which a student in chemistry begins his researches in the laboratory. He tries certain bottles, and puts one fluid with the other to see the result, and arrives at no practical conclusion, because, in nine cases out of ten, he obtains, by mixing four or five bottles together, a black dirty-looking liquid: so, by jumbling together all sorts of manuring matters, and trying to obtain from them any really useful practical results, you do not obtain any from which legitimate conclusions can be drawn. Thus, for instance, we frequently hear of comparisons between guano and superphosphate; but we are not told what description of guano or of superphosphate is taken. You will see, by the diagram before me, that the composition of superphosphate varies greatly. One, for instance, contains only 5 per cent. of soluble phosphate, and 1 per cent. of insoluble; while in another we have 23 per cent. of soluble, and 5½ per cent. of insoluble. Now, if you make an experiment with super-phosphate and guano, and you find the guano greatly beats the super-phosphate, you are not entitled to say that phosphatic manures are of no utility in your particular case—that a mixture of ammonia and phosphate is much more valuable on your farm than phosphate alone; for if you will look at the composition of guano, you will find that in reality you apply a much larger quantity of phosphate than you apply even in a fair average sample of super-phosphate This diagram, moreover, does not give the amount of phosphoric acid which exists in alkaline salts, and which, in good Peruvian guano, is equal to from 6 to 8 per cent. of soluble phosphate; so that, in reality, guano is super-phosphate plus ammonia. I have no hesitation in saying, that in guano, very frequently, more phosphates are incorporated with the land, than with a great many samples of super-phosphate as they are found in the market: for a super-phosphate is considered of good average quality if it contains from 25 to 30 per cent. of phosphates, of which about one-half is rendered soluble; but in guano there is in reality quite as much, if not more, phosphate present. Then, again, experiments are frequently made on land which is in a very highly cultivated state, which is so full of manure that no amount of additional artificial fertilizers can produce any effect. I have before me an account of some experiments which were published some time ago, in all of which about the same quantity of roots was produced. There is a remark, however, which throws some light upon

the experiments:—"The only objection to the field as a trial-field for manure was its high condition. It was feared that the lots might be too much alike, and this anticipation has proved correct. In the experiments as much as 7 cwt. of Peruvian guano and 14 cwt. of super-phosphate were employed, and in all instances about the same quantity of produce was obtained." Then, very naïvely, the experimenter, in remarking upon these results, says, "It is to be regretted that one or two lots were not left without any manure whatever, although we have little doubt that such lots would have yielded next to nothing." Well, if they yielded next to nothing, the land could not be in a highly cultivated state. It is evident, I think, that the land was in a state super-saturated with manure, and experiments made on such land are not calculated to throw much light on the efficacy of manuring constituents. I have alluded specially to the question of the efficacy of phosphates and ammonia, in illustrating the direct utility of a knowledge of chemistry to farmers, and I might also have illustrated the same thing by alluding to the various forms in which manuring substances ought to be applied to the land in order to produce the maximum effect. Thus, for instance, I might have alluded to the question, In what state phosphate ought to be used in agriculture? It is plain that for a quick-growing crop, like the turnip crop, food ought to be present in a readily-soluble condition; but, at the same time, I think we cannot lay down a general rule that, under all circumstances, phosphates, which we apply in the shape of artificial manures, should be always perfectly soluble. I make this remark, not because I think it is a question with which the theoretical man has much to do, but it is a question which can be decided in a purely practical manner. Supposing the farmer finds that his land is of such a porous character that bone-dust when used in a finely-divided state becomes sufficiently available to yield him a good crop of turnips, then he would be wrong to go to the expense of buying super-phosphate. What we can use in a raw, unprepared state must evidently be cheaper than what has undergone the manufacturing process. There are some soils in which the most economical way of using phosphatic manures is simply by bone-dust, to ferment it with the farm-yard manure, and, when the heap is set up in the field, to put the bone-dust between the layers, as it is carted. By this mode of fermentation the phosphates become sufficiently soluble in the soil to answer all the practical purposes for which the manure is used. There is no necessity of using phosphates in any other shape in very light sandy soils. But, under other circumstances, if the farmer, for instance, has to deal with heavy land in which the decomposition of phosphates proceeds very slowly, it is of the utmost importance to use phosphate of lime in a soluble form. What I would advise is the purchase of a super-phosphate, in which the farmer gets just what he cannot readily make himself, *i. e.* soluble phosphate of lime. If he wants insoluble phosphate, let him use it in the shape of bone-dust. Then he may be sure in what form he gets it, and does not run the risk of getting an insoluble phosphate in the shape of coprolite powder, in which condition it is of no utility whatever. But, in most instances, the advantages of applying phosphates in a soluble condition have been clearly established. The very term "super-phosphate" shows the practical use to which chemistry is applied at the present time. There are, indeed, in the common daily experience of the farmer, terms used at the present time which would greatly astonish our ancestors. Chemistry will more and more become the common property of the agricultural community, and the more carefully the principles of this new science are studied by the rising generation, the greater will be the practical advantages that will flow from the possession of such knowledge.

On the motion of Lord FEVERSHAM, seconded by Mr. WREN HOSKYNS, the thanks of the meeting were voted to Dr. Voelcker for the able lecture he had then delivered.

SPECIAL COUNCIL (after the lecture): Lord Berners, President, in the chair.

On the motion of Mr. BRANDRETH GIBBS, seconded by the Hon. A. LESLIE MELVILLE, the Council decided that memorials and other documents received from Oxford in reference to the Country Meeting of next year should be taken into consideration on the 5th of May next, when memorials and other documents would also be taken into consideration from Coventry, Reading, and Warwick.

Adjourned to May 5.

A MONTHLY COUNCIL was held on Wednesday, the 5th of May. Present: Lord Berners, President, in the Chair; Earl of Powis, Lord Camoys, Lord Feversham, Lord Walsingham, Hon. A. Leslie Melville, Hon. Col. A. Nelson Hood, Hon. William George Cavendish, M.P.; Sir John Villiers Shelley, Bart., M.P.; Sir Philip Egerton, Bart., M.P.; Sir Charles Morgan, Bart.; Sir John V. B. Johnstone, Bart., M.P.; Sir Archibald Macdonald, Bart.; Sir Edward Kerrison, Bart., M.P.; Mr. Dyke Acland, Mr. Raymond Barker, Mr. Barnett, Mr. Hodgson Barrow, M.P., Mr. Bramston, M.P., Mr. Barthropp, Mr. Brandreth, Mr. Caldwell, Colonel Challoner, Mr. Druce, Mr. Foley, M.P., Mr. Brandreth Gibbs, Mr. Hamond, Mr. Fisher Hobbs, Mr. Holland, M.P., Mr. Wren Hoskyns, Mr. James Howard, Mr. Hudson (of Castleacre), Mr. Humberston (Mayor of Chester), Mr. Huskinson, Mr. Jonas, Mr. Kinder, Mr. Langston, M.P., Mr. Lawes, Mr. Lawrence, Mr. Miles, M.P., Mr. Milward, Mr. Pain, Mr. Shuttleworth, Mr. Slaney, M.P., Mr. Thompson, Mr. Torr, Mr. Turner (of Boston), Professor Voelcker, Mr. Burch Western, and Mr. Jonas Webb.

His Grace the Duke of Marlborough, of Blenheim Park, Oxfordshire, was elected a Governor of the Society.

The following new Members were elected:—

Bradburne, John Hanbury, Pipe-place, Lichfield, Staffs.
Brogden, John, Priory-gate, Sale, Cheshire.
Cawton, William, Somersall Hall, Chesterfield, Derbyshire.
Clay, Charles, Walton Grange, Wakefield, Yorkshire.
Corbet, Dryden, Sundorne Castle, Shrewsbury
Crane, Edward, Foston, Montford, Shrewsbury.
Forshaw, Thomas, Latus Hall, Goosnargh, Lancashire.
Garne, Robert, Northleach, Gloucestershire
Gaskell, Henry Lomax, Kiddington Hall, Woodstock.
Hill, L. Broadbent, Back Hall, Chester.
Holland, Charles, Keele, Newcastle, Staffordshire.
Howard, Robert, Broughton Hall, Wrexham.
Howell, John, Ewen, Cirencester.
Laing, Samuel, Hordle Manor, Lymington, Hampshire
Logan, John, Maindree House, Newport, Monmouthshire.
Matthews, Henry, Montford, Shrewsbury.
Mein, William, Home Farm, Blenheim, Oxfordshire
Millard, James, Rugeley, Staffordshire.
Perry, Samuel, Shipley, Bridgenorth, Shropshire.
Sisson, Robert James, Talardy, St. Asaph.
Sugden, David, Huddersfield, Yorkshire.
Thomas, James, Lidlington, Ampthill, Bedfordshire
Woods, James, Stowmarket, Suffolk.
Woods, Edmund Freeman, Stowmarket, Suffolk.

FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented the monthly report on the accounts of the Society, showing a current cash-balance of £1,298 in the hands of the bankers; and laid upon the table, for the information of members, the usual quarterly statements of income and expenditure, and of assets and liabilities.

TRIAL OF IMPLEMENTS.—The President having called the attention of the Council to the completion this year of the triennial arrangements for the trial of Implements at the Country Meetings of the Society, and to a consideration of the propriety of its renewal or discontinuance for the future, it was carried, on the motion of Mr. Fisher Hobbs, seconded by Colonel Challoner, that a committee, consisting of the Members of the Implement Committee, and of Mr. Howard, Mr. Shuttleworth, Mr. Caldwell, Mr. Huskisson, and Mr. Amos, be appointed, with power to confer with a deputation from the body of the Implement Makers, and to report to the Council at their next monthly meeting in June.

EASTERN COUNTIES' RAILWAY.—On the motion of Mr. Fisher Hobbs, the President undertook to address a letter to the Chairman of the Eastern Counties Railway Company, on the subject of the charges, made only by that company, for *live stock* sent for exhibition at the Country Meetings of the Society.

COUNTRY MEETING DINNER.—On the motion of Mr. Torr, seconded by Mr. Thompson, the Council decided unanimously: "That in future, if any dinner be held at the Country Meetings under the patronage of the Society, the entire management shall be vested in the local committee; but the Council shall have the option and power of reserving and taking such a number of tickets as it shall think fit; and this Society shall nominate the Chairman, and supply the list of toasts, but shall have no other liability connected with it."

COUNTRY MEETING OF 1859.—The report of the Inspection Committee having been read, and deputations received from Coventry, Reading, Warwick, and Oxford, the Council decided that the country meeting should be held at Warwick, next year, on condition that the Mayor of that city entered into the usual agreement with the Secretary of the Society by the next Monthly Council on the second of June. These deputations consisted of sixty-four members, among whom we remarked the following:—

His Grace the Duke of Marlborough.
The Lord Bishop of Oxford.
The Rev. James Clutterbuck, M.A.
The High Sheriffs of the counties of Berks., Oxford, and Warwick.
Right Hon. Edward Ellice, M.P.
Right Hon. Edward Cardwell, M.P.
The Sheriff of Oxford.
The Mayors and Town-Clerks of Coventry, Oxford, Reading, and Warwick.
Sir Joseph Paxton, M.P.
Earl of Macclesfield.
Viscount Dillon.
Mr. Palmer, M.P.
Mr. Greaves, M.P.
Earl of Warwick.
Lord Willoughby de Broke.
Lord Guernsey.
Lord Leigh.
Mr. Harcourt, M.P.
Colonel North, M.P.
Mr. Repton, M.P.
Mr. Mark Phillips.
Sir T. G. Skipwith, Bart.
Sir Paul Hunter, Bart.
Mr. Pigott, M.P.
Aldermen Moore, Spiers, and Ward.
President, Vice-President, and Secretary of the Oxford Farmers' Club, and Deputations from the Rugby, and Dunchurch Association, and the Council of the Birmingham Cattle Show.

COUNTRY-MEETING QUERIES.—On the motion of Mr. Raymond Barker, seconded by Mr. Brandreth Gibbs, a committee was appointed to revise the printed queries (in use since the year 1841), and adapt them to the present requirements of the Society, consisting of Mr. Raymond Barker, Mr. Brandreth Gibbs, Hon. W. G. Cavendish, M.P., Mr. Brandreth, Mr. Barnett, Mr. Fisher Hobbs, and Mr. Milward.

EDITORSHIP OF JOURNAL.—Mr. Jonas having moved the consideration of the best course to pursue for the future Editorship of the Journal, Mr. Thompson, Mr. Dyke Acland, and Mr. Wren Hoskyns favoured the Council by an expression of their willingness to continue their Joint-Editorship provisionally until some other arrangement should be made. On the motion of Mr. Raymond Barker, seconded by Sir John Shelley, Bart., M.P., it was carried, that the Joint-Editors be authorized to expend a sum not exceeding £300 per annum, for such aid as they might require.

LECTURES.—Mr. Thompson reported from the Journal Committee their recommendation that Professor Henfrey should be requested to deliver a Lecture before the members at the Weekly Council on Wednesday, the 26th of May, at half-past 12 o'clock, on some subject connected with Vegetable Physiology. The Mayor of Chester's communication of an offer from Mr. Moffat to deliver a lecture at the Chester Meeting, on Atmospheric Influence in connection with the Potato Disease, was referred to the Journal Committee.

DISTRIBUTION OF JOURNAL.—On the motion of Mr. Milward, seconded by Mr. Jonas Webb, the Council decided that the rule by which no governor or member in arrear of subscription had a claim to receive the Journal should be strictly enforced.

SPURIOUS GUANO.—Sir John V. B. Johnstone, Bart., M.P., read the following report from the Chemical Committee:—

Professor Voelcker has submitted analyses of Cotton-cake, containing a larger proportion of oil and flesh-forming matter than Linseed-cake; and also various specimens of factitious guanos perfectly resembling genuine Peruvian guano in colour and smell, containing only from one-fourth to one-third of genuine Peruvian guano. He has also exhibited to the Committee specimens of guano from Kooria Mooria and the Falkland Islands, as well as from Ichaboe; all inferior to the extent of from one-fourth to one-half of the best Peruvian guano. At the suggestion of the Committee Prof. Voelcker has undertaken to prepare a short report on these specimens, to be submitted to the members of the Society at the next Weekly Council.

CHESTER MEETING.—Mr. Fisher Hobbs reported from the Chester Committee the favourable progress of the arrangements for the ensuing Country Meeting, to be held in that city in the third week of July next.

STEAM-CULTIVATORS.—Sir Archibald Macdonald, Bart., as Senior Steward of Implements for the Chester Meeting, having represented the importance of an efficient trial of Steam-Cultivators at the Chester Meeting, the following resolution on the motion of Mr. Thompson, seconded by Mr. Miles, M.P., was carried unanimously:—"That a committee be appointed consisting of the Implement Committee, with the addition of Mr. Caldwell and Mr. Huskinson, to consider the memorial presented by four owners of steam ploughs, and to endeavour to secure an efficient trial of steam ploughs or cultivating implements at the Chester Meeting."

STEWARD OF POULTRY.—On the motion of Sir rchibald Macdonald, Bart., seconded by Mr. Fisher Hobbs, Mr. Harcourt Powell, of Drinkstone Park, Suffolk, was unanimously appointed Steward of Poultry for the Chester Meeting.

VICE-PRESIDENT.—On the motion of Mr. Jonas, seconded by Mr. Torr, his Grace the Duke of Rutland was unanimously elected one of the Vice-Presidents of the Society, in the place of the late Lord Braybrooke.

MEMBER OF COUNCIL.—On the motion of Mr. Torr, seconded by the Hon. A. Leslie Melville, Mr. Hutton, of Gate Burton, Lincolnshire, was elected one of the General Members of Council, in the place of the late Mr. Stephen Mills.

GUTTA PERCHA.—A communication from the Society of Arts on the supply of Gutta Percha, and its employment in the manufacture of agricultural tubing, was referred to the Implement Committee.

THRASHING MACHINES.—Suggestions for the trial of thrashing machines were received from Mr. Algernon Clarke, and also referred to the Implement Committee. Adjourned to May 12.

A WEEKLY COUNCIL was held on Wednesday, the 12th of May, present: Lord Berners, President, in the Chair, Duke of Rutland, Lord Camoys, Lord Walsingham, Hon. A. Leslie Melville, Hon. Colonel Hood, Hon. William George Cavendish, M.P., Mr. Raymond Barker, Mr. Brandreth, Mr. Davey, M.P., Mr. Brandreth Gibbs, Mr. Glegg, Mr. James Howard, Mr. Fisher Hobbs, Mr. Hutton, Mr. Pinder Simpson, Mr. Slaney, M.P., Mr. Tanner, Colonel Towneley, Mr. Wilson (of Stowlangtoft), and Mr. George Wood.

PROFESSOR VOELCKER, the Consulting-Chemist of the Society, transmitted the following reports of his recent investigations on the subject of cotton-seed cake for feeding cattle, and on the fabrication of spurious guanos, so completely similar in external characters to the genuine articles as to have deceived the most experienced dealers, and to have their inferior value detected only by means of chemical analysis.

I.—COTTON-SEED CAKE.

I have the pleasure of submitting to the inspection of the members of the Society copies of analyses of two samples of a new kind of Cotton-seed cake. Both samples, under the name of decorticated Cotton cakes, were lately offered for sale at London and Liverpool respectively. An inspection of the subjoined analyses will show that this new kind of cake is superior in nutritive properties to any sample of Cotton-cake which I previously examined. It will be observed that both are extremely rich in flesh-forming principles, as well as in oil and fatty matters. Indeed both specimens of Cotton-cake contained a great deal more of these valuable constituents than the best Linseed-cake, and ought to be, according to the analyses, more valuable as a feeding stuff than Linseed-cake. I would observe, however, that the analytical results obtained in the examination of feeding stuffs like oilcake are insufficient in themselves to determine their relative practical feeding value. Various circumstances, too numerous to be detailed in this place, affect the practical value of articles of food. Thus the oil in Cotton-cake may not be so readily assimilated as the fatty matters in Linseed-cake, or it may not agree with the constitution of animals, or the cake may be disliked by beasts and sheep, or contain something or the other, not usually ascertained by analysis, which may affect its practical utility. Indeed nothing short of actual feeding experiments will suffice to ascertain in a satisfactory manner the comparative value of this Cotton-cake and Linseed-cake. But as Cotton-cake, much inferior in composition to the samples analyzed by me lately, has been used for feeding purposes with considerable advantage, it is highly probable that the experience of practical feeders will prove that decorticated Cotton-cake is an economical substitute for the much more expensive Linseed-cake.

Composition of two samples of decorticated Cotton-seed cake.	No. I.	No. II.
Moisture	8.27	7.67
Oil and fatters matters	19.19	14.93
Mucilage, gum, and sugar	12.25	14.47
* Protein compounds (flesh-forming principles)	42.62	40.21
Pure cellular fibre (woody fibre)	10.22	11.45
Inorganic matters (ash)	7.45	8.27
	100.00	100.00
* Containing nitrogen	6.82	6.91

II.—SPURIOUS GUANO.

Notwithstanding the facility of detecting admixtures in genuine Peruvian Guano by simple chemical means, fraudulent adulterations of this most important of all artificial manures appear to continue unabated in some quarters. During the last two months, more than ten samples of factitious and of adulterated guanos were sent to me for examination, which circumstance induces me to direct again the attention of the members of the Society to the subject of adulteration of guano. I have the pleasure of presenting for inspection several samples of bad guanos, and have selected specimens which best illustrate the peculiar character of the adulterating materials. An analysis of each specimen is attached to the bottle containing it. A comparison of the composition of these adulterated manures with that of genuine Peruvian Guano, of which a specimen is also exhibited, will show how much money a purchaser loses in buying such bad guanos, even if sold 2*l.* or 4*l.* less than Peruvian guano can be obtained from Messrs. Gibbs and Co. At the same time it will be evident to any one who examines by the unaided senses the various specimens on the table, how utterly impossible it is for any one to distinguish several of the adulterated guanos from the genuine Peruvian. The fact is, the guano-mixers have acquired such skill in their ne-

farious practices, that neither by the touch, smell, nor the eye, the adulterating materials can be detected. It is now a common practice to sift off the harder lumps in Peruvian guano, to mix the fine dust most intimately with extremely finely powdered chalk, gypsum, yellow loam, sand, or whatever the adulterating material may be, and to add afterwards the lumps of genuine guano, so as to give adulterated guano the outward characters of the best Peruvian. The expense to which fraudulent dealers go, in preparing in a sufficiently fine state the admixtures in order to obtain a perfectly uniform powder with the fine guano-dust, is very great; but if it be considered that often guano worth only 4*l.* per ton is sold at the full price of the best Peruvian, it will easily be conceived that a good margin for profit is left, notwithstanding the expense. The specimen marked No. I. is a guano which does not contain, I believe, a particle of Peruvian guano, and is altogether a clumsy imitation. It is surprising that such stuff can find purchasers. This so-called guano consists entirely of fine yellow loam, sand, gypsum, chalk, a little salt, and organic matters poor in nitrogen, since this so-called guano furnishes, on decomposition, little more than 1½ per cent. of ammonia. At the utmost, this manure is worth only 3*l.* 3s. per ton.

No. I.—Composition of a sample of guano warrauted Peruvian, but altogether artificially made up, value only £3 3s. per ton.

Moisture	7.06
* Organic matter and ammoniacal salts	14.56
Phosphates of lime and magnesia (bone earth)	17.55
Oxides of iron and alumina	3.82
Sulphate of lime (gypsum)	18.49
Carbonate of lime (chalk)	10.11
Alkaline salts (common salt chiefly)	6.63
Insoluble silicious matter (sand)	21.78
	100.00

AUG. VOELCKER.

*Containing nitrogen	1.50
Equal to ammonia	1.82

No. II. is a guano, which has all the appearance of an excellent sample of Peruvian, but which contains in reality only about one-fourth its weight of genuine Peruvian guano, and no less than three-fourths its weight of yellow loam and chalk. Instead of 16 per cent. of ammonia, this guano contains not quite 7 per cent. of ammonia, and scarcely is worth £4 4s. per ton :—

No. II. Composition of adulterated guano sold at Liverpool at £12 per ton.

Moisture	5.35
*Organic matter and ammoniacal salts	16.20
Phosphates of lime and magnesia	8.48
Oxides of iron and alumina	5.90
Carbonate of lime	15.89
Magnesia	.76
Alkaline salts (common salt chiefly)	3.10
Insoluble silicious matter (sand)	44.32
	100.000

AUG. VOELCKER.

* Containing nitrogen	3.14
Equal to ammonia	3.82

This guano contains only one-fourth of its weight of Peruvian guano and three-fourths of yellow loam and chalk. The specimens marked No. III. and IV. are not quite so bad as the preceding one, but still they are bad enough, and contain only about one-third of Peruvian guano, and two-thirds of foreign admixtures. In No. III. the chief adulterating materials are chalk and sand; in No. IV. there is less chalk and much gypsum, as well as yellow loam and fine coprolite powder. Both guanos are worth about £5 per ton. The following table exhibits the composition of these two adulterated guanos, in contrast with that of genuine Peruvian guano :—

Composition of a genuine and adulterated Peruvian guano.

	Genuine Peruvian.	Adulterated Guano.	
		No. III.	No. IV.
Moisture	15.90	9.38	12.86
*Organic matter and salts of ammonia	53.73	24.21	19.33
Phosphates of lime and magnesia (bone-earth)	22.07	16.06	22.12
Carbonate of lime (chalk)	None	30.30	5.12
Sulphate of lime (gypsum)	None	3.91	15.57
Carbonate of magnesia	None	—	2.63
Alkaline salts	7.17	3.45	3.75
Insoluble silicious matter (sand)	1.13	12.69	18.62
	100.00	100.00	100.00
*Containing nitrogen	15.74	5.65	5.09
Equal to ammonia	19.11	6.86	6.18

AUG. VOELCKER.

I have also the pleasure of placing on the table specimens of guano from the Falkland Islands, Kooria Mooria, inferior Ichaboe, and African guano. By far the most valuable of these is the Falkland Island guano, which, however, is not near so valuable as the best Peruvian guano, since it contains much less ammonia. The Kooria Mooria guano is rich in phosphates, but, like the sample of inferior Ichaboe guano and the African guano submitted to inspection, poor in ammonia. In comparison with the price of the best Peruvian guano, inferior guanos from other places are generally sold also high. In conclusion I beg to observe that in buying Peruvian guano a farmer requires no other guarantee than a letter in which the dealer engages to supply "Peruvian guano, best quality." No expensive analysis is required to test the honesty of the dealer, since a perfectly trustworthy opinion can be given whether the guano is genuine or adulterated, and the ground of an examination, which the members of this Society have the privilege of obtaining at the trifling sum of 5s.

Mr. FISHER HOBBS expressed the great satisfaction it gave to himself, as it would doubtless also give to the other members of the Society, to find their Consulting Chemist thus furnishing to the Council, for immediate announcement to the agricultural community, the practical result of his researches. He was glad to find that at the small expense of 5s. each member had the privilege of obtaining a certificate of the true value of any substance offered to him for purchase as genuine guano. At Mr. Hobbs's suggestion the thanks of the Council were ordered to be transmitted to Prof. Voelcker for the communications he had then made to them, along with a hope on their part that he would continue, from time to time, as they occurred, to furnish such results of investigations carried on in his laboratory as he might think of immediate practical importance.

ANNUAL VETERINARY REPORT.

The following Annual Report was read from the Governors of the Royal Veterinary College :—

In presenting their annual report to the Council, the Governors desire in the first place to express their gratification that during the past year nothing has occurred to disturb the harmony which has so long and so advantageously existed between the Royal Agricultural Society and the Royal Veterinary College. They see in this continued co-operation an assurance that the agricultural community fully appreciates the efforts which are made to advance the science of veterinary medicine in its application to the diseases of cattle, sheep, and pigs, and thus to raise this important branch of the healing art above the practice of the uneducated empyric. During the past year the Governors have had under consideration several important questions relating to the instruction of the pupils, and they early took means to render this as practical as scholastic discipline would permit, by the appointment of a new demonstrator of anatomy, so as to relieve the professors from having to occupy so much of their time in mere expositions of the arrangement of the structural parts of the animal body. The carrying out of this plan has been attended with the happiest result, as the professors have been enabled to extend their lectures and demonstrations on the nature and causes of the various diseases affecting domesticated animals. With reference to the lectures specially devoted to the subject most important to the interests of the general agriculturist, nothing has occurred to prevent their regular delivery four times a-week throughout the entire session, and they have been attended by the whole of the pupils of the College; and with what success, is shown by the fact that the proportionate number which have passed their examination, and been admitted members of the Royal College of Veterinary Surgeons, has been greater than in former years.

Pathological Anatomy.—Throughout the past year there has been received from the members of the Society very many valuable specimens of disease, accompanied by the history of the cases in which they occurred, and these have been made available for the information of the pupils by the demonstrations and explanations of the Professor of Cattle Pathology in addition to his other instructions. The Governors desire to give encouragement to this means of making the education of the pupil as practical as possible, because, from circumstances which would appear to be irremediable, few cattle are admitted as patients at the college. It is a matter of regret to the Governors that no measure which has been tried by them in conjunction with the Society has availed to bring to the College Infirmary a sufficient number of oxen, sheep, or pigs, when the subjects of disease. Even the merely nominal scale of charges which was adopted a few years since for medical attendance, operations, keep, &c., of such animals, has failed in effecting this most desirable object; and the Governors are at a loss to know what more can be done to remove the apathy which exists in the agricultural body with reference to this important means of imparting practical information to the pupils. By thus again directing the attention of the Council to the subject, the Governors would hope that some good may be done.

Pupils.—The number of pupils which have been admitted to the College is somewhat greater than before, and, as previously stated, they have been most regular in their attendance, and will, after receiving instructions for two sessional years, be eligible for examination by the Court of Examiners, under the provisions of the charter granted to the Royal College of Veterinary Surgeons. It may perhaps be necessary to direct the attention of agriculturists to the fact that very many persons who call themselves veterinary surgeons and are practising in various parts of the country have not received the diploma of the College, nor, indeed, have attended any lectures on veterinary science; while others have entered as pupils, remain only a short time, and then gone into the country to practise with but an imperfect knowledge of the principles of the healing art.

Practice of the College.—Although but few cattle have been admitted as patients, yet some very interesting and unusual cases have found their way into the infirmary; and notwithstanding it has not been customary to particularize these, in consequence of thereby unnecessarily increasing the length of the Annual Report, still the Governors are desirous of adverting to one of almost unique character, namely, an affection of the base of the brain in a heifer belonging to Stewart Marjoribanks, Esq. The symptoms in this case were very remarkable, and afforded matter for deep reflection on the part of the physiologist as well as the pathologist. The attack was somewhat sudden, so much so as to lead to the belief that the animal had sustained an injury of the skull, but this was entirely disproved by the *post mortem* examination. The change in the structure of the brain was found to depend upon a scrofulous diathesis, and it raised the question as to how much of the disease was due to hereditary influence. It is matter of importance to the breeders of cattle that scrofula has of late years been considerably on the increase among what may be otherwise designated the better breeds of animals.

Inspections.—The visits into the country by the Veterinary Inspector, on the authority of the Council, have not been very numerous this year, and the Governors would be glad to see that the arrangement which has been made with regard to the inspection of diseased cattle on the premises of agriculturists was likewise in more general use; for they believe much good would result therefrom, not only in arresting the progress of disease, but in investigating the causes, with a view to their removal, on which it was found to depend. At the country meeting of the Society at Salisbury the Inspector was in attendance, and the Governors were much gratified to find by his report that fewer cases of hereditary defects and diseases were existing among the animals there brought together than at any former meeting of the Society. By far the most important investigation of the year which has been made by the inspector is that of the nature and character of the continental disease of cattle, known by the name of the steppe murrain, rinderpest, &c., and which excited so deep an interest in the minds of the whole community for fear of its introduction into this country. It has not only been shown by him that the rumours of its having extended from the steppes of Southern Russia, which may be regarded as the home of the peat, to those countries whence foreign cattle are exported for the supply of our meat markets, were groundless, but that there is scarcely a probability of its reaching this country. Besides this important result of this mission to the continent, the public are likewise now made familiar with the natural laws which govern the spread of the malady, as well as with those preventive measures which continental governments have found most effectual in meeting its progress. Nor would the Governors omit to state as a matter of congratulation to the Society, that the investigations which were made by the Inspector, in daily watching the affected animals, noting the symptoms, and subsequently instituting a searching examination of the lesions found upon death, have enabled him to

arrive at a far more satisfactory conclusion of the true pathology of the pest than had hitherto been obtained, and even by those who had for years been practically acquainted with it. The Governors were much gratified to find that not only did the Royal Agricultural Society unanimously agree in the selection of their officer for this important duty, but that the other two National Agricultural Societies of Scotland and Ireland concurred in the choice which had been made; and they are also very desirous of stating that the report which the Inspector has published on the subject has excited a lively interest throughout the continent, and is regarded as a valuable addition to veterinary literature by the new light it has thrown upon the nature of this mysterious and destructive cattle pest.

In presenting however their Annual Report, the Governors are wishful not to extend its dimensions by reference to their several endeavours to do justice to the object sought to be obtained by the union of the two institutions, because they believe that these are equally as familiar to the Council as to themselves, and they would therefore merely conclude by assuring the Council of their full determination to use all the means at their disposal to elevate veterinary science in its application to the diseases of all domesticated animals.

(Signed) on behalf of the Governors of the College.

RICHARD BEAUVOIR BERENS, V.P.

A SPECIAL COUNCIL was held on the same day, present: Lord Berners, President, in the Chair, Duke of Rutland, Lord Camoys, Lord Walsingham, Hon. A. Leslie Melville, Hon. Colonel Hood, Hon. W. G. Cavendish, M.P., Mr. Raymond Barker, Mr. Brandreth, Mr. Brandreth Gibbs, Mr. James Howard, Mr. Fisher Hobbs, Mr. Hutton, Mr. Slaney, M.P., Colonel Towneley, Mr. Wilson (of Stowlangtoft), and Mr. George Wood.

STEAM CULTIVATORS.—Mr. Thompson, Chairman of the Special Committee appointed "to consider the memorial presented by four owners of steam-ploughs, and to endeavour to secure an efficient trial of steam-ploughs or cultivating implements at the Chester Meeting," transmitted the following Report, which on the motion of Mr. Brandreth Gibbs, seconded by Lord Walsingham, was received and unanimously adopted by the Council:—

1. That the prize of £500 offered for the best Steam Cultivator can neither be withdrawn nor divided for the present year.
2. That so long as this prize is offered by the Society, all trials of steam-cultivators must take place in competition for it.
3. That in specification No. 1 in the prize sheet the judges be instructed to interpret "Steam-cultivator" to mean, plough or other cultivating implement worked by steam, provided that all the other conditions specified be complied with.
4. That steam-cultivators shall be in the yard not later than Monday the 12th of July, and the trials commence on Tuesday the 13th.
5. The stewards of the Implement Department shall be at liberty, if they think fit, to have the performance of each implement in this class written out and appended to it in the show-yard.

Adjourned to May 19.

A WEEKLY COUNCIL was held on Wednesday, the 19th of May. Present: Lord Berners, President, in the Chair; Mr. Raymond Barker, Mr. Pickin, Mr. Burch Western, and Mr. Wilson of Stowlangtoft.

Communications were received: 1. From the Rev. W. W. Harvey, of Buckland Rectory, Herts., on three cases of severe personal injuries which had occurred recently in his own neighbourhood in the cases of persons connected with unguarded agricultural machinery. 2. From the Henderson Fund, soliciting aid on the part of the Society. 3. From Sir Philip Egerton, Bart., M.P., a Parliamentary Report on the operation of Boydell's Traction Engine. 4. From Mr. Smith, of Woolston, proposing a trial with his steam-cultivator, as shown at Chelmsford, "to farm cold clay land, hilly and uneven, for four years, against any combination of steam-ploughs that may be shown at Chester, no manure whatever being employed, the horse-power not to exceed the ordinary seven-horse engine manufactured by Ransomes and Sims, and the result to be decided by the total produce, cost, and condition of the land at the end of that period of trial." 5. From Mr. Douglas, an essay on the potato disease. 6. From the British Minister in Switzerland, a copy of Dr. Rupener's new work on the application of veterinary principles to the management of domesticated animals.

DISEASE AMONG SHEEP.—The President reported information he had that day received from Leicestershire on the outbreak of a disease on the udders of ewes, which rendered them hot and sore. The disease was confined at present to particular flocks, and had not yet been taken by barren ewes or lamb-hogs. At the President's suggestion, it was desired that animals infected by this disease should be sent direct to the Royal Veterinary College.

AUDIT.—The half-yearly audit of accounts was held on Friday, the 21st of May. Present, Mr. Raymond Barker, chairman, and Colonel Challoner and Mr. Wilson, members of the Finance Committee; and Mr. George Raymond Barker, Mr. Astbury, and Mr. Joseph Druce, auditors on the part of the Society. The accounts from the 1st of July to the 31st of December being examined, audited, and found correct, were certified accordingly.

SPECIAL COUNCIL.—A Special Council was held on the same day, for the purpose of taking into consideration the Report to be made by the Council to the ensuing General Meeting: present, Colonel Challoner, Trustee, in the Chair; Earl of Powis, Mr. Raymond Barker, Mr. Druce, Mr. Shuttleworth, and Mr. Wilson, of Stowlangtoft. The Report was agreed to accordingly.

GENERAL MEETING.—The Anniversary General Meeting of the Society was held on Saturday, the 22nd of May, agreeably with the terms of the Charter: present, Lord Berners (President), in the chair, Lord Feversham, Mr. Raymond Barker, Mr. Milward, Colonel Challoner, Mr. Hercy, Mr. Joseph Druce, Mr. Searson, Hon. W. G. Cavendish, M.P., Mr. Burch Western, Hon. Colonel Hood, Mr. Pickin, Mr. Jonas Webb, Mr. Corbet, Mr. Shuttleworth, Mr. Davey, M.P., Sir Wm.

Pell, Bart., Mr. Payne, Hon. A. Leslie Melville, and Mr. Lawrence. The usual preliminaries having been gone through,

The SECRETARY (Mr. Hudson) read the Report of the Council, which was as follows:—

REPORT.

The Society consists at the present time of—

81 Life Governors,
133 Annual Governors,
904 Life Members,
4010 Annual Members, and
18 Honorary Members,

Making a total of 5146 names on the list.

The Council have elected Mr. Thompson, of Kirby Hall, a Trustee of the Society, in the place of the late Earl Spencer; and His Grace the Duke of Rutland a Vice-President, in that of the late Lord Braybrooke. They have also elected the Hon. Colonel Hood, Mr. Humberston (Mayor of Chester), Mr. Huskinson, and Mr. Hutton, General Members of the Council, to supply the vacancies created respectively by the transfer of Viscount Eversley to the class of Vice-Presidents, and Mr. Thompson to the class of Trustees, and by the decease of Mr. Simpson and Mr. Stephen Mills.

The funded capital of the Society stands at £9,264 8s. 11d. stock in the New Three per Cents.

The Chairman and Vice-Chairmen of the Journal Committee have announced to the Council that their respective personal engagements will not allow them to devote as large a share of attention as they have hitherto done to the editing of the Journal; but they have subsequently acceded to the request of the Council that they should continue their services until some permanent arrangement shall have been made. The Council, in order to diminish the amount of the mechanical details connected with their labours, have placed at their disposal a grant not to exceed £300 annually, for the purpose of engaging such literary aid as they may find requisite for the more convenient editorship of the Journal.

The excellent paper on horse-shoeing, by Mr. Miles, of Dixfield, near Exeter, published in the last part of the Journal, has been reprinted in a cheap form for extensive distribution, and already upwards of a thousand copies have been sold.

The Governors of the Royal Veterinary College have presented their annual report of the progress made at that institution in the application of the veterinary art, and the diseases of cattle, sheep, and pigs. They state that the number of pupils qualified to act as practitioners in carrying out the objects of the Society in this point of view, continues to increase; but they regret that the members of the Society do not avail themselves more extensively of their privilege of sending diseased animals in a live or dead state to the college, and thus furnish means for a larger amount of practical experience to the Professor of Cattle Pathology and his pupils.

The Council have appointed Professor Voelcker, of the Royal Agricultural College at Cirencester, as the consulting-chemist to the Society; and he has already delivered before the members his inaugural lecture on Agricultural Chemistry in its Relation to the Cultivation of Root-crops. They have also made arrangements with Professor Henfrey, of King's College, for the delivery of a lecture on Vegetable Physiology, on Wednesday next, the 26th of May. This lecture, as in the case of Professor Voelcker's, will be taken down in its full extent by a short-hand writer, and immediately made public. The Council hope that this early publication of the lectures, by at once placing before the agricultural community any facts of an important practical character, will be found to meet the wishes of the members.

The Chester Meeting promises, from its variety and extent, to be of an interesting character. The Council have made special arrangements for the trial of steam-cultivators, by which their relative merits will be tested during the whole of the week previous to that of the meeting; and they have decided that machinery in motion shall be exhibited on the same plan as last year. The Council have adopted the recommendation of the Local Committee, that a dinner should take place in the Music Hall at Chester, capable of accommodating 500 guests. They have decided that, for the future, when a dinner is proposed at the Country Meeting of the Society, the whole arrangements shall be made and expenses borne by the Local Committee, the Council reserving to themselves the right of appointing the Chairman, and of preparing the list of toasts; and that, after the present year, the show of poultry as a portion of the Society's exhibition shall be discontinued.

The Council have appointed a committee to report upon the propriety of renewing or discontinuing, after the current year, the triennial arrangement for the trial of implements, adopted for the Chelmsford, Salisbury, and Chester meetings.

The Council have selected Warwick as the place of the Country Meeting for the year 1859; and have decided that after the year 1860 they will be prepared to hold a Metropolitan Meeting, should circumstances be found favourable in the meantime for the adoption of such an arrangement.

By order of the Council,
JAMES HUDSON,
Secretary.

On the motion of Mr. DAVEY, M.P., seconded by Mr. DRUCE, the Report was unanimously adopted.

Mr. R. BARKER rose to nominate the President for the year ensuing the meeting at Chester. He had, he said, the honour to propose for the office of President, at the termination of the current year, his Grace the Duke of Marlborough—a nobleman who had only very recently become a member of the Society, but who had already manifested great interest in its proceedings. His Grace had only presented himself once in that room; and he then appeared as the leader of a deputation from the county of Oxford, which came there to request that that county might be selected as the one in which the Society's show should be held in the year 1859. All who were present on the occasion were struck with the amenity of manner, the zeal in the cause of agriculture, and the aptitude for business evinced by his Grace in addressing the large auditory which was assembled; and if the deputation did not succeed in their object, their disappointment was at all events attended with this advantage, that it tended to convince the agricultural community and the public at large that no amount of influence could deter the members of the Council from exercising their judgment impartially and deliberately in the decisions which they came to, on matters of deep interest to the Society (Hear, hear). For his own part, he must say he thought the Council had made the best selection; and if they had given the preference to a county which was better entitled to it than Oxford, he trusted no unpleasant feelings had been created by that circumstance. Nothing could be more courteous or gratifying than the manner in which his Grace had received the request that he would

allow himself to be nominated for the office of President; his Grace having observed that, while he should shrink from entering into competition with any other candidate for the post, he would undertake the duties of the office if it were the wish of the leading members of the Society that he should do so. He (Mr. Barker) was to have seen his Grace that morning; but instead of that he had received from him a letter, which he held in his hand, written from the House of Lords on the previous day, in which he said that he now waived all objections to his nomination, and would leave the matter in the hands of the meeting. Under these circumstances, he felt great pleasure in proposing that the Duke of Marlborough should be the President of the Society for the year succeeding the Chester Meeting (cheers).

Lord FEVERSHAM felt very great satisfaction in seconding the motion. As a relative of the noble duke he might perhaps be suspected of some partiality in the matter, but he was sure the meeting would give him credit for sincerity when he said that he would not consent to second the nomination were he not convinced that the Duke of Marlborough was a person who would discharge the important duties of the presidency with great credit and advantage to the Society (Hear, hear). It was, as they were no doubt all aware, not long since his Grace succeeded to his title and estates; but he (Lord Feversham) knew that during the time which had elapsed since the death of the late Duke he had engaged largely in agricultural pursuits, and that he was devoted to the science and practice of agriculture. He had great satisfaction, therefore, in seconding the nomination, and he felt the strongest confidence that the Society would have reason to rejoice in the choice which was, he hoped, about to be made.

The motion was put, and carried unanimously.

On the motion of Mr. JOSEPH DRUCE, seconded by Mr. JONAS WEBB, the Trustees were re-elected.

On the motion of Mr. MILWARD, seconded by Col. NELSON HOOD, the Vice-Presidents were re-elected.

After the votes had been taken in the usual manner, it was announced that the members of the Council recommended for election had been elected accordingly.

Mr. R. BARKER, Chairman of the Finance Committee, then read the following balance-sheet:—

HALF-YEARLY ACCOUNT FROM THE 1ST OF JULY TO THE 31ST OF DECEMBER, 1857.

Receipts during the Half-Year.

	£	s.	d.
Balance in the hands of the Bankers, July 1st, 1857	989	8	10
Petty Cash Balance in the hands of the Secretary, July 1st, 1857	16	6	7
Dividends on Stock	134	18	4
Governors' Life Compositions	90	0	0
Governors' Annual Subscriptions	70	0	0
Members' Life Compositions	168	0	0
Members' Annual Subscriptions	506	1	0
Journal Receipts	139	5	3
Country Meeting Receipts:— Salisbury	2805	10	4
	£4919	10	4

Payments during the Half-Year.

	£4919	10	4

THOS. RAYMOND BARKER, Chairman,
C. B. CHALLONER,
HENRY WILSON. } Finance Committee.

Examined, audited, and found correct, this 21st of May, 1858.

GEORGE I. RAYMOND BARKER,
WILLIAM ASTBURY,
JOSEPH DRUCE. } Auditors on the part of the Society.

On the motion of Mr. PICKIN, seconded by Mr. H. CORBET, thanks were voted to the auditors for their services in auditing the accounts.

The CHAIRMAN said he hoped that special attention would be paid to the report of the Veterinary Committee. It was very desirable that the members of that Society should know that if their animals were seriously affected by any peculiar disease, they might secure an inquiry into the matter, by sending specimens to be examined by gentlemen connected with the Society, in London; and further, that in fitting cases the Council would send a professor to any part of the kingdom, to examine into the causes of any disease which happened to be prevalent in the district. His Lordship then inquired if any member present had any remarks to make, or any suggestion to offer, which might be referred to the Council for their consideration?

No response having been made to this appeal,

Col. CHALLONER said he was quite sure that the motion he was about to propose would meet with unanimous concurrence. Both those who were and those who were not members of the Council would agree with him that Lord Berners was entitled to the best thanks of the meeting for the efficient manner in which he had performed the duties of the Chair on that occasion, and also for the very constant attention which he had given to the affairs of the Society ever since the time when he was elected President. (Cheers). There had been very few Presidents, since the formation of that Society, who had bestowed more time on the affairs of the Society than the noble lord who then filled the chair. His Lordship's presence rendered it impossible for him to say all that he might otherwise do on that subject; but he did feel, as a member of that Society from its commencement, and as one who had always taken great interest in its proceedings, that they were very much indebted to the noble lord for the services which he had rendered during his tenure of the office of President. (Hear, hear.) He begged, therefore, to

propose that the thanks of the meeting be given to Lord Berners. (Cheers).

Mr. CAVENDISH, M.P., seconded the motion, which was put by Col. Challoner, and carried by acclamation.

The CHAIRMAN said, when he was elected President he considered that a very high honour had thereby been conferred upon him, and he rejoiced that his conduct during his Presidency appeared to have given satisfaction to the members.

The meeting then separated.

WEEDS AND WEEDING.

My last paper chiefly referred to the eradication of weeds from the fallowing lands. This however is but a small part of the subject; and as my aim is to make these papers practically useful, I do not intend to give any detailed description of the weeds of agriculture further than will suffice to bear upon the question as to the best means to insure their extirpation. A simple enumeration of the names of many of these worst pests to good cultivation will enable every experienced farmer to recognise them. It will however be necessary to my purpose to give some slight notice of each specimen of these weeds, in connection with such suggestions as may be presented to me, in passing, relative to their habits of growth, injurious tendencies, and modes of destroying them. First,

THE WEEDS MOST COMMONLY INFESTING CORN CROPS.—They are principally the following (I give their most common names): The thistle or saw-wort, dock, or curled dock, carlick or ketlock or charlock, red poppy or canker weed, goldens or corn marigold, corn bind weed, daisy weed or gowans, darnel or drauk, cockle, blue-bottle or knap weed, wild carrot, kecks or hemlock, hariff or cleavers, fat-hen or wild spinage, willow weed, hog weed or wire grass, sow thistle, wild oat, field scabious, fox-glove, hemp nettle, fumitory, rag wort, wild parsnip, and many others. These are the most injurious weeds as growing up with, and interfering in, the progress of the crop. There are many others which are denominated under-weeds: they do not greatly interfere with or impede the growth of the crop itself, but prevent the spreading of the roots, and do great injury in its early stages. They are not so exhausting to the soil as those of larger growth, but they prevent that free circulation of air and moisture to the roots so essential to a healthy plant. They consist chiefly of the following sorts: Corn mint, shepherd's or crowneedle, chickweed or stitchwort, dandelion or horse-gowan, colt's-foot or clay weed, toadpipe or mare's-tail, twitch or squitch, black grass or slender fox-tail, groundsel or grunsel, earthnut or pignut, buttercup, ass's mart or biting persicary, persicary or passion dock, spurge, borage, louse-weed, rest harrow or wild liquorice, field madder, &c., &c.

THE THISTLE, OR SAW-WORT.—These are in great variety, and common everywhere. It is almost impossible to effect their destruction in the early stages of growth. In corn crops they must be kept down by hoeing and spudding; but on grass lands it is better to permit them to attain a size sufficiently strong for the nippers to draw them up, or the spud to cut them below their crown. In some cases it may even be desirable to let them produce seed; but before it is shed the whole should be mown and carried off the field. Many fields have been in dry seasons thus cleared.

THE DOCK OR CURLED DOCK.—This is a very hardy and injurious weed, to be found everywhere. Its roots are extremely tenacious of life, and it sheds a vast produce of seed, which are so hardy that after becoming food for birds they are deposited all over the farm for future growth. Hoeing and spudding may retard their progress, but nothing is effectual but drawing them up and carrying them off the field, or burning—nearly every particle of root will grow.

CHARLOCK, OR KETLOCK.—These are great pests, and ought to be constantly attended to, or the field will soon become yellow with their flower. The weeding and drawing must be continuous, none should be left to ripen their seeds—even where they most abound this must be prevented. With judgment, patience, and perseverance they may be got rid of. No soil will yield two good seed crops. Topping is a very partial palliative: they come as thick as ever next season. It is almost a hopeless task to exterminate them from poor soils, where they so thickly propagate; but it must be done before these can be profitably farmed; they must be resolutely dealt with.

POPPY, RED POPPY, CANKER WEED. — Light soils and lands well pulverized are most subject to this pest of the field. They abound generally in hot seasons, with occasional showers — "poppy years." The rapidity of their growth is surprising, and they often make their appearance when the crop is in an advanced stage, which makes their extermination difficult. Hence poppy extirpators are of only partial service. Hoeing deeply, and very careful hand-weeding, is the best course to pursue in this case.

GOLDENS, OR CORN MARIGOLD. — These infest many upland soils and inferior clays very injuriously, and are with great difficulty kept under. Early hoeing and constant weeding is the chief resource to keep down a weed of this kind, for its growth might be called successional.

CORN BIND WEED.—This is of the class called climbers, and most seriously affects the crop where it is heavy and laid, actually fastening it close to the ground. Its roots penetrate the soil very deeply, and its seed is hardy and yielding. It abounds in clayey loams, and is one of those weeds whose seeds injure the samples of corn. It requires more than ordinary attention to expel it from the farm. Hedgerows abound with it. It creeps almost unseen along the surface-drains and roadways, and the seeds are carried over the

land by birds, as in the case of docks. Hand-hoeing and weeding are the chief resorts, followed by continuous raking with long-toothed hand-rakes.

DAISY WEED, OR GOWANS.—These, like the corn marigold, infest poor clays greatly, and are of similar habits, and require like means to rid the land of it. It is not so successional in its growth.

DARNEL, OR DRAUK.—This is a kind of brome grass, and grows very like oats as to habit; and as it can scarcely be distinguished from the corn whilst growing, it cannot readily be weeded out. Care should be taken not to sow it, as it is an annual, and generally sown with the seed corn.

COCKLE.—This is a very pernicious weed, as greatly infesting corn samples, and detracts from its value. The seed is numerous, is rough, and almost black; it can readily be dressed out with proper sieves of seven wires to the inch. Millers dislike it much, as the seed breaks fine and discolours the flour. Weeding may do great service. Never sow it with the seed-corn.

BLUE-BOTTLE, OR KNAP-WEED.—A common weed on all sandy soils, and hard to eradicate, as are all those of a similar class. Unwearied attention must be given to rid them.

WILD CARROT, HEMLOCK OR KECKS, FAT-HEN OR WILD SPINAGE, and WILD PARSNIP are all very obnoxious intruders upon our crops, and are of similar growth and habit. Some of them are more seen in hedge-rows and ditch banks, &c. They grow rapidly, and occupy large breadths, and are thus very detrimental to the crop. Early hoeing and pulling is the best course with them. The wild spinage is most injurious to the crop, and produces a large quantity of seeds; this seeding must be prevented.

HARIFF, OR CLEAVERS.—This is a highly-injurious weed. It is a most tenacious climber, dragging down the finest crops where it abounds, and its seeds are a great drawback upon samples of corn. Early hoeing is best, and subsequently close hand-weeding, and afterwards, as for the corn bind weed, the crop should be raked over and over.

WILLOW WEED, HOG WEED, KNOT GRASS OR WIRE GRASS (IN VARIETY), PERSICARY.—These are of extremely hardy growth, and produce an astonishing crop of seed, which grow immediately they are shed, so as to bring forth innumerable plants. They will speedily spread themselves and occupy all the soil, and thus destroy the crop if not quickly looked after. Deep hoeing and constant weeding will alone suffice to keep them under. Their seeds are very hardy, and ought to be dressed out of all seed corn.

SOW THISTLE.—This is one of the most provoking of the weed tribe. It is of such rapid growth when once it takes a good hold of the soil, that it is continually making its unlooked-for appearance after weeding is concluded and the crop is pronounced cleanly weeded. This is a fibrous or creeping-rooted weed, and is best destroyed in fallowing. It is a great pest to an inferior crop of beans or peas. The winged seed fly a long distance.

WILD OATS.—This is a woful pest on poor clayey loams, and a very general weed elsewhere. It grows from roots as well as seeds, and, like darnel, it is not seen till almost too late to weed it out, without great injury to the crop. On rich loams it grows to a great height, towering above the general crop in a most unsightly manner. Never sow a wild oat; weed them out if possible.

THE FIELD SCABIOUS, THE FOX-GLOVE, THE FUMITORY, THE HEMP-NETTLE, THE RAGWORT, and many similar weeds of the like habit of growth.—These are all of the class of tall-growing weeds that impede the progress of the growing crop by taking up the required space for it. They are not of such inveterate hardihood as to defy the hoe or spud, but are more readily brought under by its destroying cut. The same constant hoeing and weeding are requisite for all, and the same careful forethought is needed to prevent their increase.

We are apt to think farming would be an easy business if it were not for all the anxiety consequent upon such comparatively trivial matters. Why it is nothing. What is common life itself, amongst common people, but a succession of like trivial things? Seldom more than petty successes; petty troubles, petty trifles every day attending us. What need for circumspection in all our conduct! What necessity for constant weeding.

I now come to those under-weeds which are so injurious to corn crops, *i. e.* twitch or squich, black grass or slender-foxtail, butter-cup, corn-mint, shepherd's or crow-needle, chickweed or stitchwort, dandelion or horse-gowan, coltsfoot or clayweed, toadpipe or marestail, groundsel or grunsell, earthnut or pignut, ass's-mart or biting persicary, persicary or passion-dock, louse-weed, rest-harrow or wild liquorice, field-madder, &c. &c. Having especial reference to practical usefulness in these papers, I must necessarily be as concise as possible.

TWITCH, OR COUCH-GRASS, &C.—This is a highly injurious weed to a corn crop. It is classed by botanists in the same genus of grass as wheat, but it is totally different in the growth of its roots, for they are found to run underground in every direction, and it does great damage to every corn crop where it abounds, by its roots running into the soil, in and about the roots of the corn plants, so as to impede their growth exceedingly. There is no help for this case, but in repeated hoeings, so as to check its growth, The roots will remain till the next fallow. Great care should invariably be given to fork it out before seeding.

BLACK GRASS, OR SLENDER FOXTAIL, commonly called Natural Grass.—This is very detrimental to the progress of the corn crop. It has not a strong creeping root like twitch, but it is almost as difficult to destroy; besides, it sheds a large crop of hardy seeds, which are much relished by birds, so that by roots, and by the diffusion of its seed, it is largely propagated. Constant hoeing is the only resort during the growth of the corn; and immediately after harvest a good harrowing should take place, to cause the seeds to vegetate, when the young plants may be mostly destroyed by ploughing. The old plants must be eradicated in the next fallow.

BUTTER-CUP RANUNCULUS. — This is very common on some soils, and is of very tenacious growth and

habit; large fibres are thrown out from the globular bulbs, and they abstract much virtue from the soil in supporting this determined intruder. These may be dug out, but it is an expensive operation where they greatly abound. Early and continuous hoeing will prevent injury to the growing crop to any extent; but a good fallow can alone destroy them. Care should be taken that they do not shed their seeds.

Corn-mint, Shepherd's or Crow-needle, Louse-weed, Toadpipe, and Groundsel, are very similar in their habit of growth, and require much hoeing and hand-weeding to eradicate them. The *corn-mint* has a larger and more hardy root, which will live for three or four years, and can scarcely be got rid of except by fallowing. The *shepherd's-needle* has a very unsightly appearance in a corn sample, and detracts much from its value. The *toad-pipe* is very wiry, and a large crop of it is a pretty sure forerunner of mildew in any succeeding crop, owing to the flint it extracts from the soil. *Groundsel* is a quick-growing plant, and if not speedily overtopped by the corn crop becomes a great bane, particularly on good loams. The *Louseweed* is chiefly seen in the stubbles on good loams. It comes late into flower, and not being well weeded out, it gives the wheat-stubble a slovenly appearance. I have only to repeat that the same process of hoeing and hand-weeding can alone mitigate the evil; but I would recommend the last hand-hoeing to take place as late as it can possibly be done, without damage to the crop. Late weeds require protracted weeding. Groundsell does great damage to young clover.

Chickweed, or Stitchwort.—This weed is often slightly treated of by our writers, but on fine friable loams it is a very pernicious weed. We have frequently seen crops of turnip-seed all but destroyed by it; and in thin wheat crops it flourishes surprisingly. Its roots are very minute and wiry, and find their way everywhere. Its seeds, too, propagate very early, and are extremely hardy, and are diffused over the land thickly by linnets. The only remark I would make here is, that, as it is lightly thought of, it is often neglected and left to propagate freely, often to become one of the worst banes to the farm.

Dandelion or Horsegowan, Coltsfoot or Clayweed, Earthnut or Pignut.—These possess very similar roots as respects their tenacious hold upon the soil. The *Dandelion* and *Pignut* are less detrimental than the coltsfoot, but they do considerable damage in impeding the growth of the corn plant. The *Coltsfoot* is one of the most obnoxious weeds we have; it is the earliest of spring flowers, and almost before other weeds are seen, its cotton-looking seeds are flying all over the lands; besides, it has a perennial root, nearly as bad as twitch, which finds its way as freely under ground, and is as hard to destroy. Many ways are resorted to for its destruction: one is to pick off its flowers; but the root-stock or eye is so tenacious of life, that it soon throws out more. It is a good plan to dig it out at flowering time; but only clean fallowing can destroy it. Pigs are remarkably fond of pignut, and similar roots, and the tending of such on fallows is often of great service in making a clean fallow.

Ass's-mart or Biting Persicary, Persicary or Passion Dock, Rest-harrow or Wild Spinach.—These are of very similar character in growth and habit. The *Rest-harrow* has a perennial root, tough, strong, and woody, but is not very abundant, and chiefly in slovenly fields. The *Persicaries* are a very vile weed on good soils; they are so hardy and prolific, both in seed and plant. On some soils, and when at full growth, it is with difficulty that the hoe can be made to cut through the root, and the crop of seeds is so extraordinarily great, that a few plants would seed a field. These, and all other plants producing great abundance of seeds, ought to be had under especial supervision by every cleanly farmer. They are annuals, and their little thickly-clustering plants almost escape notice in early weeding; but if left uncut they eventually show themselves in great profusion. It is these, and such as these, *i. e.* red poppy, hariffs, cockle, fat-hen, groundsel, chickweed, and some of like habit and appearance as young plants, that do so much harm in so many ways. In the first wheat hoeing most of them have not made their first shoot above ground, and it is by this very hoeing or culture that some of them are caused to vegetate. Farmers are often perplexed and teased to see these late weeds making such headway in the crop when it is too late to weed them out; for, although these under-weeds do not injure a full crop, they are very troublesome in a thin or light crop, and the expense of keeping them down is often very considerable. The most desirable and judicious course for every farmer to pursue, with reference to the weeds of his farm, is to give them no rest. At all times and seasons he must keep a sharp look out upon them, and wherever found make an effort to destroy them. The "higher" he farms, the more care will he require. High cultivation on a rich soil will in a remarkably short time bring many varieties of weeds to perfection, and grow others so strong and vigorous as almost to defy the hoe; or, if he is not on the alert, they grow so fast as to make their extirpation a very expensive matter of business. On all open well-manured soils it is a most difficult thing to pursue cleanly farming: either the crop must be given up for cleanliness, or there is great hazard of a foul one, and the farmer has often such perplexities to contend with. At all events he must keep his weeds under, and if my observations on this subject shall lead to any more strict surveilance of the farm, I shall be abundantly gratified.

SCOTCH COTTAGES.

The Highland Society of Scotland, which has done so much for the improvement of husbandry and the advancement of that country—and it may be said for the improvement of husbandry generally—among other worthy undertakings, offered their medal for designs of labourers' dwellings. The dwellings of the working classes have needed improvement there as much as in Ireland, and more than in England, because, being constructed when the country was poor and backward, now that it has become rich and thriving the old type of cottages was kept up, and they had become a shame to one of the foremost countries in the world. Scotch landowners thought little of this; but as the country, since the opening of railways, has been threaded by Southern visitors, the dwellings have been looked at with another eye, and it has been felt they are an eyesore to the land. Beyond a certain height, no field can be made more fruitful, and year after year must it be kept fruitful by new manures and by opening up drains; but houses last many hundred years when well made, and are a part of the national stock and wealth well worthy of care. Many of the houses in England, Flanders, and France are two or three hundred years old; and year after year, as the people grow, a few more houses are built, and the stock is kept up without any very heavy call on the labour of the year; and in a well-settled commonwealth the houses are good, strong, and well built. It is strange, nevertheless, to see the diversity of provision under this head, even in the same country; for there are parts of England with hovels; and in some parts, with stone quarries, there are mud huts; and in others, where the bricks have to be made, the houses are not good.

Scotland, it is owned, has been far behind in lodging her people, both among the Erse in the Highlands, and among the English and Danes in the lowlands and on the east shore. Her leaders are, however, awakened, and a great endeavour is made to meet the want; and as there is stone enough, and lime enough, dwellings will now be got which will last for hundreds of years. As this endeavour is to be made, it is to be wished it will be worthy of the times, and that we shall not have a stock of hovels instead of good houses. The Highland Society, feeling this, asked for designs, so that landowners and others wishing to build might have a groundwork, which could be dealt with according to means and circumstances. The medal given by the Society was won by Messrs. Hickes and Isaac, of Northgate-street, Bath, who sent in three sets of designs. One of these was for one chamber and one living-room; another, for two rooms above and two below; and a third, for three rooms above and two below. As we have lately spoken of the Irish prize designs, we think it useful to say something about the Scotch designs, which are meant by Messrs. Hickes and Isaac to meet the wants of the Scotch landowner and workman.

Messrs. Hickes and Isaac considered the system of Scotch husbandry to be such that it would be unwise to confine the cottages to one type, and therefore they provided a variety of designs. They bestowed great care on making provision for ventilation by means of air flues, and warmth and domestic convenience have likewise been studied. The privy is placed some short distance from the house at the back, and is provided with a freestone riser and a deal seat, the soil being conveyed by a syphon-pan into a cesspool, so as to be used for manure. The materials specified for the buildings are such as can be obtained in the locality for which they were designed. The elevations are of the simplest character, having dressed joints and mullions, and no attempt is made at display of any kind. The roof is without valleys, and of the simplest construction.

In the five-room cottage the entrance is by a porch of 6 feet by 4 feet, the object being to prevent the rush of cold air into the living-rooms, which is necessarily hurtful in a bleak northern climate. The porch leads into a living-room 13 feet 6 inches by 12 feet, and from which the stairs lead to the upper storey. Under the staircase is a closet. The living-room leads to a scullery 9 feet 6 inches by 11 feet, in which is a pantry. A door leads from the scullery into the back-yard. In each room is one window. On the upper floor is a parents' bed-room 9 feet 6 inches by 12 feet, with a chimney; a boys' bed-room 9 feet 6 inches by 11 feet, with a chimney; and a girls' bed-room 9 feet by 7 feet 6 inches, without a chimney. In each room is a window, and there is a window to light the staircase.

The four-room cottage is entered by a porch which leads into the living-room, 12 feet by 12 feet, and in which, as in the other cottage, the floor is of wood, as well as that of the scullery. On each side of the fireplace, which is fitted with Nicholson's grate, is a hot closet and a coal closet. The window-shutter is made so that it will form a table when needed. The same can be introduced in the other cottage. A door leads from the living-room into the scullery, which is 10 feet 3 inches by 8 feet, and has one window and one outer door. In one corner is the staircase, and in the other a meat-safe, with a coal-closet underneath. The meat-safe communicates at the back with the window.

On the upper floor the parents' bed-room is 12 feet by 12, with two windows, and Pearce's fire-lump grate in the chimney. On each side of this one hot closet and one common closet. The children's bed-room is 10 feet 3 inches by 8 feet, and has one window, but no chimney. It should be mentioned that the flues springing from the lower rooms are carried through the parents' bed-room. The staircase is lighted by a half-window in the middle of the double cottage. A good supply of windows is a great benefit in a common cottage,

and Messrs. Hickes and Isaac have so provided that there shall be thorough means of ventilation for the sleeping-rooms of the cottages. What, however, they cannot unhappily provide for is that the inmates shall open the windows, for they will long keep their horror of fresh air. The architect wants the schoolmaster and the clergyman to help him, or his labours for the health of the people are too often in vain. The people must be taught the use of a good house, and how to take care of it, for the dwellings of the poor are oftener abused than used.—Building News.

CENTRAL (STIRLING) FARMERS' SOCIETY.

DISCUSSION ON THE VARIOUS BREEDS OF CATTLE.

At the recent annual meeting of this society, held at Stirling, G. B. Home, Esq., of Argaty, in the chair, the following discussion on the various breeds of cattle took place. We wish that such discussions were everywhere the rule, instead of the absurd plastering speechifying which we too often meet with.

After the usual loyal toasts,

The Chairman proceeded to introduce the discussion on the various breeds of cattle. He said—I am not sure whether the present is the proper time to introduce this or not, especially when there is a good deal of hot punch going. However, if you allow me, I will make the few remarks I have promised to do. My own opinion is that such a practice introduced among us after our dinners may be of great use to the society, and give us in going home something to think of, perhaps more pleasant and beneficial than toast drinking. I believe we must all acknowledge that agriculture has now attained the position of a high science. There are many ways in which in other professions there is an interchange of thought; there are mechanics' institutes and other societies, where scientific men may meet and improve each other by an interchange of opinions; while many farmers, when they meet, are generally contented with bumper after bumper, and paying fulsome compliments to each other. In all this I can see very little fun, one way or other; whereas, if there was a system of discussing agricultural subjects at such meetings, a great deal of improvement might be got both by those who joined in the discussion and those who listened (Hear, hear). On the present occasion I feel rather nervous in undertaking to introduce the subject of my remarks to this meeting; but I hope that the more flourishing our society becomes, and the greater number of members who join us, the less will such diffidence or difficulty be felt by future speakers, till we have an unreserved scientific discussion on all subjects connected with agriculture. People who know nothing about it may laugh as they like; but I have no hesitation in saying that the science of agriculture requires, for its proper application and development, the highest intellect and the best education that man can receive. To carry out agriculture to perfection requires a knowledge, aye, and an intimate knowledge too, of a number of deep sciences. If a farmer is to know anything about his cattle, he must have a good understanding of the anatomy and physiology of these animals; he must know something about how to cure their diseases. In the cultivation of grain, the farmer must possess a knowledge of chemistry—of the various kinds and properties of manure, and what manures should be used for a particular kind of grain. In fact, a farmer must be ever on the stretch—all his faculties on the alert; and if he carry out agriculture properly, it must be by a high cultivation of intellect, and by an immense amount of perpetual observation. He has not only to sow the seed and see it grow, but he must be able to see what has caused it to ripen perhaps sooner than before, or what has tended to prevent it coming to maturity as it ought, or what has caused it to survive blight. In fact, there are a thousand things which a farmer has to do, and which, to be done properly, require a mind of a high order. Indeed, the highest in the land are only too happy to be considered good and intelligent agriculturists; and, however things may have gone in time past, depend upon it, agriculture will take that high place among the sciences which it so thoroughly deserves, if it be carried on in a manner corresponding with the magnitude of the interests it involves. I have undertaken to bring before you this evening as a subject of discussion the breeds and breeding of cattle. I do this because I have been an anxious observer upon these subjects for at least 30 years, and have, during that time, lost no opportunity of gaining information; and if there is one subject upon which I have a chance of talking agreeably I think it is this. I shall endeavour to speak in such a manner as to draw on the present company to say what their opinions are, and I hope every one will join in the discussion so far as any idea strikes him, and give us all the benefit of that idea. I begin with the aboriginal breeds. In the parks of Cadzow, and at Chillingham, in Northumberland, there are cattle said to be the original breed of this country. I confess I have my doubts as to whether the white breed be the aboriginal one; but I am rather of opinion that, if we have an original breed at all, it is our unsurpassed Argyleshire. I do not specify Argyleshire distinctly as if I referred to a breed peculiar to that county, but I speak of our well known black cattle, which, although reared in many parts of our country, are yet shown to greatest advantage and perfection in the county I have named. It cannot fail to be observed that good specimens of our black cattle possess almost every point that the breeders of cattle of England and elsewhere are endeavouring to produce. We all know their fineness of hide, straightness of legs, length and breadth of hind quarters, fine development of breast and chest, and we know that that

breed which is most highly esteemed, so far as you can compare a large beast with a small one, is almost exactly the same. The quality of their flesh is considered wholly unsurpassed, there being a fine degree of marble mixture of fatty matter which cannot be surpassed. It is well known that the nobility and gentry of England get up our Scotch kyloes as their finest beef. They are in a half wild state, and must be fed fat upon grass, for the Highland ox takes as long to get accustomed with a byre as another to be fed fully fat in it. As milkers, they do not excel in quantity; but the quality is shown by the manner in which they suckle their calves. I need not dwell upon this breed, but go on to a peculiar breed, viz., that reared in Galloway, Aberdeen, Kincardine, and Angus. How that breed has come to be what it is, forms a difficult question. Whether they are a species of the West Highlander somewhat changed, and having lost their horns, I don't know; but there is a peculiarity regarding them. Those in Galloway are larger and thinner from the heuk to the tail, though not so broad as others; while those in Aberdeen are broader over the back. It may be mentioned that the latter county has at this time the honour and glory of supplying what in the London market is called pure Scots, and they carry the highest price for beef in the London market. In regard to their milking properties, I have the authority of Mr. M'Combie, of Tillyfour, that they are excellent milkers; and he scouted the idea of an Ayrshire being compared with them in Aberdeenshire. I may mention that his place is by no means a garden of Eden, being without shelter on the top of a hill, and yet there are to be seen some of the most magnificent animals you can conceive. Long may the Aberdeen folks have the credit of producing the best Scots for the London market. There is another breed, called the Fife breed, which is said to have been originally a Dutch breed; but they are very few in number, and are not increasing. There are, perhaps, some present who can say something more about them than I can. I now come to the Ayrshire breed, which is one with which we have a great deal to do. That breed is generally allowed to be superior to all others for quantity of milk. The Ayrshire breeders have, for many years, been driving at that point, namely, good milking qualities, and I regret to say that I fear they have done so to the neglect of the feeding qualities. A recent writer, speaking of Ayrshires, says, that one cause of the pleuro-pneumonia is that they are bred too fine, and I am of opinion that there is some truth in this. The same writer also said, that if a breeder has a first-rate bull, he was put to his nearest relations—to his own mother, daughters, or cousins, thus breeding too much in-and-in. Whatever causes operate to produce the effect, I do not pretend to say; but it is an acknowledged fact that the Ayrshire breed are deficient in beef and growing qualities. They are, generally speaking, narrow in the chest, and cannot have a large development of lungs, so that they may be predisposed to take injury or catch cold. In regard to pleura, it is a disease the result of a cold which has hung about the animal for many months without being observed, till it could no longer escape observation, and I believe a great deal of it results from cattle being turned out too early in the spring, and left out too long in autumn, and being allowed to hang upon their legs at the gate of a field, doing no good whatever. If we go to the original of the Ayrshire breed, it will be difficult to call it a pure breed; for Mr. Orr, of Grougar, and Mr. Campbell, of Cessnock, brought Holderness cattle to Ayrshire, while Colonel Dunlop also introduced cows from Guernsey and Holland; but of whatever blood it be composed, there can be no doubt that the breeders have been successful in producing a highly esteemed description of cattle. It is quite possible for a person looking about him in Ayrshire to see the difference between the breeds. Near Kilmarnock the cattle are tolerably broad in the hook, having white muzzles, and a decided dash of the short-horn. Yellow and white cows denote the Guernsey breed, while dark brownish red and tawny muzzles betoken the Alderney cow. I happened to be at a meeting at Cumnock some years ago, and saw there what was reckoned the best bull in Ayrshire. Geordie was his name, I think, and he was the property of Mr. Finlay, of Lyonston. He was of a beautiful dark colour, with horns turning up. I said, "You may call that bull an Ayrshire if you choose; but if there is not West Highland blood there, I don't know where there is any." I was afterwards informed that one-eighth of his blood was West Highland. I remember a description of Ayrshire cattle with horns turned in towards the eyes. This was called the Crummie horns; and so completely was this understood, that a good milk cow was called a crummie. It has been found that fashion insists that the horns of Ayrshires are to be turned up, and screwing has been resorted to for that purpose. But a little dash of the West Highland settles that, without any screwing at all. [The speaker then went on to defend the crossing of breeds, as it was only by that means that a perfect animal could be raised, and then went on to speak of the short-horned breed. He said:] The introduction of short-horns may be of signal benefit to this country; but I am not far from thinking that if you keep them according to the present English rules you will not be greatly benefited by them. Some of the means at present adopted go to deprive the animal of its milking powers, and render it unnatural in its inclination to take on fat; but if they are made to keep in a good fair growing, breeding state—in fact, in that state of exuberant health which makes them suitable for breeding—the country would greatly benefit by their introduction. Unfortunately, the great run has been upon shape only, to the neglect of milking and breeding qualities. I may mention, in confirmation of my remarks about the fattening of the short-horn, that I was at the Newcastle show of the English Society some years ago, and was going round the yard with Mr. Booth, of Killerby. He was reckoned the first breeder of fat stock in Yorkshire, and was only equalled by Mr. Bates, whom he never liked to meet, so close was the competition. Mr. Booth's cattle were very high fed; and one cow he had at that show—Necklace, I think, was her name—was as magnificent an animal as one could wish to behold: but then she had, as it were,

pillows of fat sewed on to her hind quarters and along her back. I remarked that the calves of such an animal must be very valuable. He answered, "I am sorry to say I have been rather unfortunate in that respect; the calf died." After expressing my regret, I said, "Do you not think she is rather fat?" He said that "Perhaps she was a little." I saw other three cows—Faith, Hope, and Charity, I think he called them—raised from this same Necklace, and more magnificent animals no one could wish to see; but I heard shortly afterwards that he had given up the whole thing, and that he did not again appear as an exhibitor. On the other hand, Mr. Bates, instead of feeding to such an enormous extent, kept his cattle in first-rate breeding order. He told me he had got a lot of West Highland heifers, and had put short-horn bulls to them; thus producing the most admirable animals he ever saw, pictures of many of which he had hung on his walls. We must all, I am sure, regret the serious loss which has occurred at Keir, in the loss of the celebrated bull John O'Groat. I, for one, however, was not altogether unprepared to hear of such an event. If an animal is fed up to a state quite unlike healthy nature, as the rage is at present, what else can be expected? The object of what I have attempted to say is, that we should endeavour to get that which best suits our purposes by judicious crossing; and I think, whether for eating, or show, or breeding, the great point is to keep them in a good growing, healthy state, and not force them beyond what is good for themselves and those who are to use them. I have now come, I think, to the end of my tether; what I have said will, I hope, excite healthy discussion, and be the means of eliciting experience and information which may benefit us all (cheers).

Mr. STOBIE, of Ballockneck, passed a compliment on the ability displayed by Mr. Home in his introduction of this subject. He was not so well acquainted with the Ayrshire breed as to express a decided opinion, although he knew a cross between the Ayrshire and the West Highland breed was a great improvement. The Fife breed was a coarse animal, and such as he would not recommend to breeders, although he must say a great improvement in this breed had been made by several parties. The West Highland was, as stated by the chairman, a most excellent breed, and had all the good qualities which most other breeds were deficient in. He recommended strongly a cross between the West Highland cow and the short-horn bull, but was generally of opinion that crossing could not be too judiciously gone about. They must begin with two first-class animals, and endeavour to get prominent in the one what was deficient in the other, and thought they should try to carry on a good breed, and not cross too often or on every point. He took leave to mention that he exhibited two cross-bred heifers at the recent show of fat cattle at Glasgow, one of which gained the first prize, and was out of a small Ayrshire cow, by a pure short-horn bull; and he must add, it was a very fine animal, and admired by everyone. He had no hesitation in saying the short-horns and first crosses were the easiest fattened breed, and in times like these, when the farmer must get his goods quickly to market, they were the best. If they got £12 or £15 for a year-old, and only some £18 for a two-year-old, they were not paid for the year's keep, and it was desirable to have that breed which was ready at the earlist date to go to market. He concluded by expressing his thanks to the Chairman for his remarks.

Mr. M'NELLAN was delighted to see this mode of discussion introduced, and he only hoped that in future a programme would be drawn up, in order that all the members who chose might be prepared to speak if they thought proper. Regarding the subject of the discussion, he had found the short-horn the easiest fed, and a cross between the short-horn and Ayrshire exceedingly useful—in fact, as easily fed as the short-horns; and while he had reared this class to 50 stone, he could not rear an Ayrshire more than 35 stone.

The CHAIRMAN said he was very glad to hear a list of subjects spoken of. It could not have been done on the present occasion; but after the success which had attended the introduction of the method of discussion they had that night adopted, he was of opinion that the committee of the society should draw up a list of subjects, and allow each member to choose that subject upon which he had most information, or on which he could bring to bear the most personal experience and observation. The speaker then went on to remark upon the milking qualities of the short-horns being fully equal to the Ayrshire. All the dairies in London were filled with short-horns, and the Londoners were pretty well up to the way of getting most value for their money. He had known one short-horn cow that gave 18 Scotch pints (36 quarts imp.) of milk per day, and the amount of butter he did not recollect, but it was something immense; while at Keir he believed there was a short-horn cow which was a most magnificent milker. All this went to show that the short-horn breed contains all the good milking properties, but they had been destroyed by endeavouring too much to get a monstrous fat beast. He went on to say that the first cross of an Ayrshire was good, but the second was easier fed, and the nearer they approached the short-horns the easier would they get the fat put on. He believed that the first or second cross would turn out the most profitable for feeding and milking. There was one thing he was going to mention with regard to milking, namely, that if they took a quantity of Ayrshire milk, and a much smaller quantity of short-horn milk, there was every probability that the butter of the smaller quantity of short-horn is greater than of the larger quantity of Ayrshire.

Mr. KAY, of Hillhead, in a humorous speech, advocated the utility and value of the Ayrshire breed, but said that a great deal depended upon the keep and soil. In regard to crossing, he said he had tried it, and found his best plan was to come back to the pure breed again. He said there was no accounting for the differences between the richness of cows' milk. He himself had an Ayrshire cow that gave 18 pints of milk per day (36 quarts imp.), and only three pounds of butter in the week, while he had had a little cow whose milk produced a pound of butter daily.

Mr. GRAY, of Bearside, remarked that it was almost invariably the case that premiums at cattle shows were carried off by the smallest cows on the ground; and if it were possible to grow large Ayrshires, why are premiums thrown away on these small trifling animals? He related an anecdote of his going to a friend of his to purchase a bull, and when coming away he saw an Ayrshire calf which could scarcely move about. He asked what was the matter. "Nothing," said his friend; "only we must starve the calves the first year to make them fine, or they would grow up large, coarse animals." Now, he appealed to them whether this was according to nature, to starve a calf in its first year, in order that it might be small and fine, instead of what nature intended it. A good deal was spoken about cruelty to animals, and when the races came off, some of their neighbours cried out about the cruelty of the thing. Here, however, he submitted, was a much grosser instance of cruelty to animals—starving them during their infancy.

Mr. CHRYSTAL decidedly objected to the injudicious crossing, and above all things he thought that the breeds should be kept pure. If such animals could be got together as the Keir bull and Mr. Douglas's cows, he thought it would be madness to prefer crossing. He was of opinion that a short-horn bull with Angus cows would make an excellent animal; but if such were done, he would stick to the first cross, and never cross again.

The CHAIRMAN hoped, after the animated discussion they had had, that at next meeting some equally interesting subject would be brought up, and if he might be allowed to suggest, he would say that cheese-making would be a most excellent subject. Some of the cheese made in the district was good, and some nothing to brag of. He did not see why they should not be able to make cheese which would command a sale in the Glasgow market, as that from Ayrshire does. If such a subject were determined on, it might be well to have a show of cheese on the same day, when the various prize lots could be brought to table, and the system of making explained (cheers).—Stirling Journal.

THE ENGLISH FARMER IN FRANCE.

SIR,—We compete with all the world in growth of corn, and are not allowed the same liberty with other crops. That seems hardly just—hardly *free trade*. And when the price of wheat is extraordinarily depressed, as, unfortunately, it now is, the unfairness of this must often present itself to the minds of your readers.

Tobacco is perfectly acclimated to the north of France. The climate is similar to ours; if there is any difference, the winds are colder than in England. Here it is abundantly grown, at a good profit, under the especial fostering care of the Government; thus greatly benefiting the farmer, enabling the cigar to be purchased for a *half-penny*, and receiving a revenue of more than our malt-tax.

I had the pleasure of paying a visit to Monsieur Lecat, at Bondues, about six miles from Lille, who is the largest and most successful tobacco grower in this department; he has received many medals from French and foreign societies, and the decoration of the Legion of Honour, and has also published a work on the cultivation of it, consequently I could not possibly have met with a gentleman more competent to give me the best information. He has the most extensive farm-yard and buildings I have seen. I could fancy it was an old-fashioned English homestead, with large pigeon-house in the centre, so often seen in England. The land about it is all the very finest loam, not a stone nor a water-furrow.

The history of tobacco may be stated in few words:—Found by Columbus in 1492, introduced into Europe 1560, deprecated by all; in 1624 Pope Urban VIII. excommunicated all who used it; 1674 it became more popular, and a duty was here placed on it, and the cultivation then began. In 1810 a decree was passed by the French Government, greatly promulgating its growth; and from thence, under many alterations of the laws relating to it, it has progressed to the present time. The expenses of growing it, per English acre, are as follows:—

	£	s.	d.
Ploughing, harrowing, rolling, carting..	2	16	0
The seed bed	1	12	0
Manuring £25, but half is supposed to be left for next four crops; so it is.....	12	10	0
Manual labour	10	16	0
Sundries	1	10	0
Hail-storm insurance.....	0	18	10
Delivery, &c.	0	8	0
	£30	10	10

No small sum, but the return is often £50. The labour of it employs all the family of the small farmer, and the large one has the satisfaction of giving employment to very many of his poorer neighbours. It has been one of the principal causes of the total abolition of naked fallow, and the perfect cleanliness and heavy manuring of this part of the country.

There are seventeen species, but three only are sown; and of these, one (the large-leaved) nearly supersedes the other two. It is a fine plant, and has been known to attain the height of 7 feet 6 inches, with many branches covered with leaves; the flowers are of a purplish colour, the pods oblong, containing innumerable seeds. (Any gentleman wishing for any, if he inserts his address where to send it in the *Mark Lane Express*, I will give him some with pleasure.) One plant will produce 300 pods, and in one pod was counted 2,700 seeds, thus producing an increase of 800,000 for one. It will keep for years, and, unlike corn, requires no change of soil. Before you draw your plants from the seed-bed, select the forwardest for seed: it is ripe in October, and when cut is best hung up in a dry place, and not knocked out till wanted.

Choose a warm, protected place for the seed-bed; dig in autumn; leave it till February, then manure it well with rape-cake and pigeon's dung (here they do it at a cost of 4s. 2d. per rod!), and dig it in very shallow. Rake it very fine, and invariably between the 10th and 25th of March sow your seed, mixed with sand or ashes; cover it with branches to keep off wind and frost, and if there is no wall, surround it on three sides with *strawed hurdles* set up endways. You must also have a small bed sown ten days later, to produce plants to fill up blanks. From the moment of sowing, daily care is required; protection from grubs, weeds, sun, wind, frost, and drought. One-and-a-half rods of bed are required for every acre planted.

The field for planting must be free from trees; tobacco likes not shade. Prepare the ground as well as possible; it cannot be too fine: among other good reasons, it better bears a dry season. Liquid manure and guano are not allowed to be used by Government, as the whole cultivation of this plant is regulated by law. Only a certain number of acres are permitted to be grown in proportion to the size of the farm. Rape-cake is the best manure; it produces the handsomest and best flavoured tobacco: an acre requires three tons of it, and eighteen loads of dung.

Planting begins on the 25th of May, and it should be proceeded with as quickly as possible, as the later plants do not ripen so well as the others. To regulate the spaces they use wire chains, the links of which are 16 inches long, as that is the distance the plants should be apart, and the rows 20 inches. They are not allowed to plant thicker than 19,200 to the acre, nor thinner than 12,800. In dry weather you must not begin to plant till 2 o'clock; and if very hot, a small handful of wet chaff must be put to each plant, to remain for three days. The next operation is to mould them up. In about a month the heads are nipped off, leaving only eight leaves—requiring a skilful workman. This seems to promote suckers, which must be removed three or four times as they appear. In the beginning of September the harvest commences. Women strip the plants of the leaves, laying them in the next row already done, dividing the smaller ones from the others, as they are dried separately. A few hours are sufficient to prepare them for stringing into "garlands," and they are then ready to be carried to the drying-house. This is the most important part; on this greatly depends the quality and *classification* of the leaves. Six "garlands" are hung on a rod, and these rods are placed on other rods, which run the whole length of the shed; here they are protected from rain or damp, and constantly attended to, for twenty-five to forty days, according to the weather. You then choose a fine day to remove it to the granary, where it must be carefully surrounded with a wall of straw, to keep out the damp or air as much as possible.

The delivery of the tobacco to the Government factory at Lille commences at the beginning of January and ends in March; to effect this, the leaves must be sorted into four classes, and tied in bundles of fifty leaves each, and fifty bundles make a truss, tied with osiers. All leaves which have suffered from rain, hail, or imperfect drying, are classed as unsaleable. The *average* weight of five years' growth, from 1849 to 1853, in the district by Lille, was 24 cwt. to the acre. M. Lecal considers it by far the most profitable crop the farmer has. It strikes me it would be still more so in England.

The Government *buys all*, and fixes the prices annually: last year they were 117s., 92s., and 61s. per cwt. for first, second, and third classes. An ancient convent of immense size in Lille is applied to the manufacture; it employs 350 workmen and 400 women. The French tobacco is never used alone; it is mixed with all other sorts. The process of manufacture is very simple: Cleaned, sorted, heaped with strong brine and well heated, cut by a *chaff-box*, dried, damped and heated again, and packed. The cigars are the women's work. It all takes some time, but the snuff is the longest. After undergoing various processes for six months, it remains for a year in immense heaps of forty or fifty tons each, to acquire a scent, which it has not before. To be more minute would be uninterestiug; suffice it to say little or no machinery is required, and had we the liberty, I am sure the farmers of England would immediately try it, and, I believe, with every chance of success. Why not, if it answers so well here?

Another favourite growth is flax. I will send you a more detailed account of it, as that is open to us, and I know the prejudice against it. Now all expenses of farming here are so similar to ours, that their profits are not a bad test if there is any advantage in adopting their crops.

I am anxious not to lose a day in forwarding to you the information I have obtained on the growth of sorgho, a plant which I believe will, in a very short time, become one of general cultivation in England, with great advantage to all stock-keepers, producing more food per acre than any other summer crop, and of a more fattening nature than any of our present produce grasses or soiling plants; equally good for horses, "cattle" both grazing and store, cows, sheep, and hogs; eagerly devoured by all, sheep perhaps liking it the best; and improving as well the quality as the quantity of the milk and butter. Cows that have had half-a-cwt. per day give a quart more milk per day.

So much do I think of it, that I shall leave no means neglected which may lead to the distribution of the seed, with instructions for sowing. The outlay of a few pence for sufficient to try its qualities and capabilities in English soils is so trifling, that I should think no one who reads your journal will neglect to embrace the opportunity I offer of so easily acquiring a knowledge of this valuable plant.

I admit we have not had many useful new crops introduced into England during the last twenty years, or which realized the anticipations caused by the flattering character given them at the first, such as trifolium and many others; but that is no reason for not making inexpensive trials when we are enabled to do so. One of the most useful seeds we could desire would be for an intermediate crop between the harvest and following spring. I do not say such is sorgho, but it may be so. If sown in

July it produces two cuts; so, surely, if sown in August it will produce one.

At all events here its utility is not problematical; it is an accomplished fact, but all its uses may not yet be developed.

It was introduced five or six years ago by Monsieur de Montigny, the French Ambassador at Shanghai, who also sent over the "igname" as a substitute for the potato—(More of this some future time) by sending new seed to the Agricultural Society of Paris.

In August, 1855, the Committee of Agriculture appointed a deputation to inquire into its merits. September 4th, they found at the farm of Monsieur de Daire, at St. Roche les Amiens, a small piece six yards by seven, which was then six inches high. They went again on the 22nd of same month, and found during these 18 days it had advanced to 30 inches.

Oct. 22, 1857, in the *Napoleonien Moniteur de la Somme*, was inserted: "Many of our farmers have had great success this year with the sorgho plant grown for hay. It has given most extraordinary crops: one piece produced at *each cutting* 21,000 kilogrammes on 42 acres and 20 centares. Now this is equal to 60 tons per English acre, for all the three cuttings—20 tons per acre each mowing."

March 7, 1858, the *Mercuriale des Halle*, at Marches, says: "Seven hectares were sown last year by Monsieur Noüel, at the farm Isle Commune, St. Denis en Val-Soirct. The produce of one cutting on one hectare *was weighed*, and it amounted to 73,000 kilogrammes; it was consumed by 80 fatting bullocks, and 10 horses, from Sept. 2nd to Nov. 10th." This is 30 tons per English acre at one cutting. These accounts may be looked upon as correct; there are too many officials here to give information to the authorities, and too many agriculturists anxious for the truth in this sort of statements, to allow me to think for a moment there is any doubt about them. In fact, I believe the Minister of Agriculture would cause the editor to be punished in some way, if he allowed untruthful statements of crops to appear in his paper. It does seem most enormous, and yet it is also added: "Had it been cut at twice, the amount of weight would have been much more." The land, no doubt, was as rich and as highly manured as almost any in the world. However, if we get two-thirds of this, we need not be dissatisfied.

In the South of France it is grown for sugar; sown one-fourth the thickness, and allowed only to produce one stem, which is harvested in October, and contains fifteen per cent. of sugar—the leaves being given to cattle. This I do not expect will ever be done in England, consequently I will confine my observations to its applicability to hay or cattle soiling.

It may be sown from the 1st of March to July; the early-sown producing three mowings, the later two. You cannot over-manure for it, as the coarseness of it seems not to affect the love the cattle have for it, nor its fattening qualities. As soon as land is ready, you hoe out lines two inches deep and a foot apart, and drop the seed in these lines from three to four inches apart. It is a very branching plant, and requires room: on a large scale, of course, it would be drilled. It is covered in the usual way, and in a couple of weeks is seen just coming through; in two more it is four inches high. You will now hoe it when you please: it will only require once doing, as it so smothers the weeds that they cannot grow. But being at these intervals, a horse-hoeing would not be a bad thing, with two horses, each walking in the furrows four yards apart, and two hoes following them, and at each end of the work the hoes being set one row nearer each other. In this way the plant is never trodden by the horses. I never saw this done except by the market gardeners near London, but it is an excellent plan. It seems not to be so rapid in its growth in its early phases as afterwards: for that reason it would not be amiss to steep the seed before sowing. In June it is a yard high, and fit to commence cutting. Should you prefer making it into hay, now is the time. It is said to lose two-thirds of its weight, but here they sadly overmake all their hay and clover. The latter end of June and July is a time when a crop like this comes in very conveniently for soiling—the tares are done, the first crop of clover is all cut, and the after-grass in the meadows is not yet ready. If not mown till arrived at full maturity, it attains the height of eight to nine feet; and, from what I have heard, I believe in that state, if properly harvested and cut into chaff, all things would eat it, and thrive on it exceedingly. There seems little risk of a plant, as no insect will touch it. When the crop is finished in November, and you plough it up, the roots are excellent for hogs, boiled like potatoes. Thus all is valuable. I believe, although we may never produce sugar from the full-grown stems, we may make an excellent white wine, or vinegar, and even molasses. At all events such things have been made from it in this North of France, where I am this 19th day of May sitting by a good fire, and feeling glad I have it. Whatever they do here, I am sure we can do; but until we know that it will ripen sufficiently perfectly to produce the required quantity of saccharine matter for these purposes, it would be useless to fill your paper with an account of the different processes. Suffice it to say, they are so simple that they come within the means and powers of the smallest farmer; indeed, here it is considered as great a boon to the little as to the large cultivator. During this summer I shall most likely see much more of the management and uses of this plant, and shall most certainly forward to you any further information I may obtain, and think of interest to my brother-farmers.

AN ENGLISH FARMER IN FRANCE.

Lille, May 19th, 1858.

THE PROGRESS OF AGRICULTURE IN AMERICA.

If there is one country more than another, to which the agriculturists of the United Kingdom have looked with some feeling of apprehension, it is to the United States of America. Indeed a *primâ facie* view of the subject might seem to justify their fears. When we look at the vast amount of fresh land of the most fertile quality continually brought under cultivation, coupled with the increased facilities for bringing the produce of those lands to market in Europe, there appears good ground for supposing that increased quantities of cereal food will annually be exported from thence to Europe, to the injury of European agriculture; subject as the latter is to heavy expenses from which the American farmer is exempt.

A nearer view, however, of the system pursued in the cultivation of the virgin soils of the United States, and of the acknowledged consequences of that system, will show that such apprehensions are groundless; and that although fresh land, to a large extent, and of great fertility, is continually being brought under tillage, the aggregate produce of cereal food, adapted to the European market, does not more than keep pace with the requirements of the growing populations.

We have now before us a work on the agriculture of the eastern part of the United States;* and although we are bound to admit that great efforts are put forth to induce the American farmers to adopt the European system of agriculture, the quantity of land cultivated in an efficient manner is infinitesimally small, compared with that which is farmed upon the old and normal plan adopted by the first settlers. We would give the Boards of Agriculture of the United States every credit for the efficiency with which they perform *their* part in laying down the true principles on which the land *ought* to be cultivated; but, with all deference to their local knowledge and experience, we are convinced that as long as fresh land is cheap and accessible, so long will the scourging system of cultivation be pursued by an overwhelming majority of the farmers, by which so much of the land in the old States has been reduced to sterility, and the aggregate acreage produce so much lessened.

It has been said that a sterile soil is usually better cultivated than a fertile one; and that the principal reason why England exhibits features in farming almost equal to gardening, is that the soil, generally speaking, is so inferior that it awakens all the energy of the cultivator to raise a remunerating produce. This rule, however, does not hold good in New England or Massachusetts. There the soil is certainly inferior in quality to most of the States; notwithstanding which, the scourging system has been at work there to such a degree as to extort the following statement from a speaker at the Massachusetts Agricultural Society's meeting: "One thing is certain, that under the influence of *practical farming*, as it is called, the land of New England has notoriously deteriorated to such an extent, that it is estimated that at least a thousand millions of dollars (£200,000,000 sterling) would be required to repair the effects of a wasteful and exhausting system of cultivation."

Again, in the report of the committee on farms of the Essex (N. E.) Agricultural Society, it is stated that notwithstanding premiums are offered of fifty dollars for the best-managed farms, only two competitors presented themselves, and one of these afterwards withdrew. Similar admissions are made by the committees for other societies. But a more striking proof of the hostility of the farmers generally to improvements, is the fact, that when a comparatively small sum was required to conduct a farm for experimental objects by the State, it was refused by the House of Representatives, although the tax individually would have been of the most homœopathic amount.

Now, when we consider that New England is the foremost State of the Union, in the encouragement of agriculture by the authorities; and that notwithstanding this, the produce of wheat has decreased in forty years 50 per cent. per acre, oats 40 per cent., Indian corn 70 per cent., sheep 70 per cent., &c., &c.; we may conclude that in the other States the same process of deterioration is going on; and that the accession of new land to the cultivation of cereal crops does not more than compensate for the falling off of production on the old land, and the increased consumption consequent on the increase of the population. We know from universal admission that in the State of Virginia, the drastic character of the tobacco cultivation, as conducted there, has reduced that fertile soil to such hopeless sterility, that a large portion of it is no longer cultivated, and the State itself is now what is called "a breeding State"—that is, chiefly devoted to raising negro slaves for the Southern market; the most degrading and ignoble purpose that can be conceived. It is also admitted that not only in all the old States, but even in those new ones that have been cultivated the past twenty years, the same process has produced the same effect, and after a few years the yield of corn, wheat, oats, &c., falls off; no manure, generally speaking, being applied to make good the waste of materials.

When therefore we hear of prodigious crops in the United States, ready to swamp all the European markets, we may conclude that it is nothing more than that boasting for which our transatlantic relatives are so much noted. We have heard much of this gasconade the last few years, but have felt little of

* Fourth Annual Report of the Secretary of the Massachusetts Board of Agriculture, with the Reports of Committees, &c., with an Appendix, &c., &c. Boston, U. S.: William White, printer to the State. 1857.

its force. Since last harvest, for instance, which was to have been productive of great results, there has been less wheat and flour shipped from the States than for three years past. This may have been partly owing to the panic, which certainly prevented exportation *before* the frost set in. Still that ought to have caused a larger export trade this spring; and yet we hear that we are not to expect any considerable shipments of flour during the summer. The fact is, our prices are either too low, or the flour is wanted at home, the latter being the most probable solution of the question—or the want of money would compel the shipment, now that the panic has subsided, at whatever price, were it not that a safer market (and a better) is found at home.

There is one department of the exhibition at the Massachusetts *cattle shows* that has rather startled, as well as amused us. We give the account in Mr. Parkhurst's (secretary to the Plymouth A. S.) own words:

"The most attractive scene of the whole show was to take place at ten o'clock—the exhibition of *female equestrianism*, which did not take place till eleven o'clock. Twenty-six ladies entered their names for premiums: but thirteen appeared on the ground. The cavalcade left the village about eleven o'clock, and went around the track once, each lady accompanied by a gentleman, and presented themselves before the judges' stand. By order of the judges they performed a variety of evolutions, riding in pairs, in quartets, all together, and each lady alone, riding slow or fast, as best suited her taste or convenience. After performing an hour or more, they left the ground. These equestrians performed their parts—so far as we are capable of judging—well. Many of them laboured under disadvantages: their horses were not thoroughly trained to the saddle. There were a few good horses, but generally they were not fit for the occasion. The question comes up, whether this is the proper place for ladies to exhibit for premiums?—whether the fairest of Nature's workmanship should be shown for money, *in connection with the grossest animals and the products of the land?* I think not."

Is not the Secretary rather hard on his fair friends? At any rate here is another hint for us at home. We have long maintained the national advantage of giving premiums for well-bred horses, but it remained for our transatlantic friends to culminate the attractions of such an exhibition.

THE PRACTICAL VALUE AND APPLICATION OF TOWN SEWAGE.

There are certain questions, more or less directly affecting agriculture, with which the Legislature would appear to be very loath to deal. There is the law of landlord and tenant, for instance, in many ways susceptible of improvement and adjustment. And when we press for as much, our rulers calmly hear us out, and answer, "Had not you better settle this amongst yourselves, and make it all a matter of private agreement? We would really rather not interfere." Then, again, we wish for some uniform system of selling our produce. It is quite a puzzle now to know what we should reasonably ask and have. Here we are courteously met with the rejoinder "that unanimity must be the herald of uniformity. So long as you differ so much amongst yourselves, once more, we would really rather not interfere." And for a third point there is the sewage of towns, of such immense value to the farmer, if he can only be brought to think so. What will he give for it, or how shall we give it to him? The Government is still by no means over-anxious to interfere. Theirs is yet a Fabian policy. It may or may not be of value, and the farmer cares or does not care about it. The best way will be to appoint another Commission to inquire into the matter. And another Commission is appointed accordingly; and the Chancellor of the Exchequer goes back to his budget, and the Premier to his several little troubles at home and abroad; while we return to the argument of liberal covenants, sale by weight or measure, national settlement, repeal of the malt tax, and so on.

As regards this question of town sewage, it is pretty generally admitted that the festina lentè plan of approaching it is by far the most discreet. The last Commission, indeed, which has now been at work something over twelve months, is in anything but a hurry. The report it has just issued is in reality little more than "a feeler," offering or sanctioning suggestions as to how the sewage may be got rid of, and how occasionally employed. It is not our purpose here to follow, or to attempt to follow out a plan, itself by no means developed. The subject, however, has gradually become one of some interest to the agriculturist. He has, at any rate, heard so much about it. In fact, whenever it turns up in conversation he expects almost as a matter of course to be complimented by some worthy citizen on his indifference and stupidity. He will be told how after-ages will scarcely credit his suffering such valuable matter to be wasted. And when, perhaps, with his patience exhausted, he demands how he is to use it, or prevent its being wasted? the worthy citizen bates his breath, and but echoes the official answer, "Let us have another Commission."

It is only a few years since that the assumed value of sewage for agricultural purposes very nearly led us into mischief. The wild talk of a few amateurs, and the wonders of Tiptree hall, Myer mill, and Cumming park, were not without their effect. There were schemes, in short, as plentiful as blackberries, whereby the sewage of towns was to more than pay for its distribution. Its value to the farmer was infinite, until one day, in Hanover-square, Professor Way told him what it really was worth. And this once more put the cunctando drag on the amiable enthusiasts. We had

another Commission, with such men as Professor Way and Mr. Lawes on it. It is their report which is now before us. Since their appointment they have visited officially LOCALITIES WHERE SEWAGE IS APPLIED TO LAND IN A LIQUID FORM:—Rugby, Watford, Edinburgh, Rusholme, Mansfield, and Milan—LOCALITIES WHERE WORKS FOR THE PURIFICATION OF SEWAGE ARE IN OPERATION:—Croydon, Leicester, Tottenham, and Cheltenham—And the FARMS of Lord Essex, at Cashiobury; of Mr. Mechi, at Tiptree; of Mr. Wheble, at Bulmersh Court; of Mr. Kennedy, at Myer Mill; of Mr. Telfer, at Cumming Park; of Lord Breadalbane, at Luing; and of Mr. Harvey, near Glasgow. The Commissioners very properly decline any close comparison between the application of the liquid manure of a farm and the general use of town sewage for the same purpose. They do not give any detail of the places they visited; but they find that sewage in its liquid state is profitably applied to *grass* land in the neighbourhood of Edinburgh, as well as of Milan. It is gradually going out of use for arable land; while the formation of a solid manure from it, at one time a very popular project, it is shown, "will not be remunerative." The commissioners thus cautiously sum up their experience. After enumerating various difficulties, drawbacks, and expenses, that we need not recapitulate here, they so declare themselves:—"The Commission, *however*, believe that *on the whole* there can be no doubt that the sewage of a town, in a liquid state, can be *more* profitably disposed of by direct application to land than by any other means, *provided* that, relatively to the population producing it, the area to which it is applied be *small*, that its use *be limited to grass*, that all *natural levels be taken advantage* of, and that the works be characterized by skill and a *judicious economy*." This reads careful and honest. With skill, economy, natural facilities, and good judgment, the sewage of towns *may* be of service. Of course the Commissioners found endless mistakes and extravagance in its application so far; and on many of the sites that had been spoken to as very models for our adoption. Had the agriculturists of this country been only half as ready to act on ill-considered advice as some people were to give it, we dare scarcely contemplate the serious loss that would have been the consequence.

And yet there are some of their friends, even now, that will tell them the same sort of thing. A week or two since, the Society of Arts had a special meeting to discuss this Report of the Royal Commissioners, and for any one who chose to say anything he liked on so attractive a subject. The Society has already made itself rather famous in this way. Neither Mr. Chadwick nor his opponents were, unfortunately, or fortunately, present; but an M.P.,—Mr. Lawrence Palk—was. The honourable gentleman came, too, armed with the usual kind of ammunition. He was from Devonshire, "where the system of irrigation was by no means new." He had been to Leicester, and "witnessed Mr. Wickstead's plan of deodorization"; and "he held in his hand a letter from Mr. Campbell, of Rugby." One knows but too well what this all means, and how the honourable gentleman must finish, as he did, in this wise—

"This was a question which was well worthy the attention not only of gentlemen connected with large towns, but also of those who, like himself, were connected with the agricultural interests of the country. If they looked to the increasing value of guano, and the difficulty there was in obtaining it pure, he thought it was important that science should be brought to bear, in order to retain for the use of the agricultural districts that which was the bane of large towns, but which was of such extreme value to the farmer."

Another substitute for guano—well worthy of the attention of the agricultural interest—and of such immense value to the farmer. Now, in plain sober English, what does this really come to? Just this: that under certain circumstances, and with very good management on his own part, the farmer may be able to employ the sewage of towns to some advantage. Why can we not be content with saying so much, instead of running away with superlative expletives, and crying up plans that have so far proved neither altogether profitable nor practical? Mr. Lawrence Palk represents an agricultural constituency, and if so be he expects his supporters to act up to what he says, the less he says about this matter the better. It is such wild work on the part of those who undertake to advocate the farmer that does so much mischief. One would suppose, with the case of Mr. Palk and his water-meadows before us, that we could not spend too much of our time and means in arriving at the grand consummation embodied in the use of town sewage.

The Royal Commission is luckily composed of stouter stuff. Few men understand the farmer and his wants better than Professor Way and Mr. Lawes. They unite in a report that treats the use of sewage for agricultural purposes as but a matter of secondary consideration. We have always been inclined so to regard it. Let the towns get rid of their refuse as best they can, and let the farmer use it when he can. With certain facilities at occasional sites it may answer its end; but let no plan go out of the way to assume that the use of sewage is to be attended with "extreme value" one way or the other.

TO DESTROY WIRE WORM.—Procure a sufficient quantity of nitrate of soda to allow 1½ cwt. per acre; have it well broken on a hard floor, and sifted through a fine sieve, in order that it may dissolve the quicker, spreading made equal to the plants. It is advisable to sow it when the ground is damp; but it often happens that at this season such is not the case, consequently it is advisable to use the hoe after sowing the nitrate to admit it to the root of the oats, and to sow in the afternoon, taking the chance of a heavy dew. I consider nitrate of soda the greatest fertilizer ever known, also the quickest in its operation. I have seen it, when the ground has been in a moist state, change the countenance of the oats in four days. In Cuthbert Johnson's "Encyclopædia of Agriculture, &c.," in the treatise on the wireworm he quotes a statement from a Mr. Tallant, who affirms that he has frequently freed fields infested with wireworm by sowing white mustard.—CHARLES NEWMAN, Court Farm, Reading.

CALENDAR OF AGRICULTURE.

Continue during the first part of June to prepare the land for turnips, which are sown as speedily as possible during the last half of the month. Use farm-yard dung in a warm or soapy condition, not wholly cooled, but in the latter fermentation. Open drills at 26 inches distance; spread the dung evenly along the furrows in a quantity that no bare ground is left; reverse the drills over the dung. Sow the turnip seeds on the fresh tilth, and in dry seasons roll the drills lightly to exclude drought and retain moisture. In sowing turnips with auxiliary manures, as bones, guano, ashes or rape-dust, use Hornsby's drop-drill, which sows two rows at regular intervals of nine inches, the manure and turnip seed mixed together, which affords a ready food to the young plant.

Plough pared and burned lands with a light furrow, and produce a fine tilth by ample harrowing, before sowing the seeds during the latter part of the month. If the land be clayey and stiff, sow on the furrow slice, well harrowed. On loamy soils reduce the land by workings, and drill it; well mix the soil and the ashes. Sow rape and cole seed for winter food. Plough lands from which winter tares have been consumed; harrow the surface into fineness, and sow the turnip seeds in rows by means of a machine with lengthened coulters to make ruts. Sow in broadcast the headlands of the turnip fields; and use short dung that is easily covered.

Horse and hand hoe beet-roots, carrots, and parsnips—allow not one single weed to be seen.

Potato drills, not rolled after being planted with sets, may now be harrowed; plough deeply the intervals of the drills with the miniature plough, which is the best implement yet devised for stiff-bottomed lands; keep the hand-hoes and scuffler constantly going, break all clods, and pulverize the soil very deeply and freely. Fine earths are essential to all root crops.

Continue the feeding, in the yards, of cows and horses, with clovers and vetches; feed amply, provide abundant littering, and convey the superfluous liquid to the tank; but it is best when absorbed by straws and culms.

Cut all tall weeds from among the grain crops; allow not any weeds to perfect the seeds on pastures, in fences, or on road sides. Many seeds are winged, and carried by the wind to a distance, and propagate very rapidly.

Finish the shearing of sheep this month: examine the animals closely, as they pass through hands at this time, in the mouth, the shape, the quality of the wool, and in the general appearance. An inspection of the animals at this time, and the putting upon them distinctive marks, will very much assist the sorting of them for the tupping season in October.

Put mares to the stallion every fortnight. Wean lambs by placing them at once beyond hearing the bleat of the ewes, and give them the best grass on the farm.

Hay cutting will commence this month. Ted the grass quickly behind the mowers; put into cocks, spread them out and cock it again, and carry to the rick. Employ plenty of hands, at least six to each mower. Turn clovers in the swathe without tedding, as much shaking loses the leaves, which are the best part of the plant. Put the grass into large cocks, which may stand in the field for a time. When hay gets damaged by rains, the quality is somewhat recovered by mixing salt in the ricks 30 lbs. to a load.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR MAY.

Although the weather has been by no means warm for the time of year, arising from the numerous changes in it, vegetation has made considerable progress; and in most parts of the country it may be considered seasonably forward. In our large grain districts, the young wheats have continued to wear a healthy appearance; and very few of our farmers appear disposed to doubt the return of an average crop. Of course, as yet, it would be premature to offer any decided opinion on this important matter; but certainly present appearances are very favourable. As regards the spring crops, which for the most part are growing rapidly, our advices are satisfactory. Very few reploughings have been found necessary; and the loss of plant has been smaller than for some years past.

A highly interesting report on the subject of the progress of agriculture in the United States, under the fostering influence of Congress, has just come to hand. A bill has been lately introduced, with every prospect of success, for granting to the several states 6,340,000 acres of land, for the purpose of promoting and encouraging agricultural colleges, and schools for the mechanical arts. There is to be apportioned to each state a quantity equal to 20,000 acres for each senator and representative in Congress, to which the states are now respectively entitled. This is undoubtedly a wise measure on the part of Congress; and it is to be regretted that a similar scheme could not be carried out in the United Kingdom. Amongst other matters referred to in the report in question, we are informed that over 400,000,000 acres had been granted to fifteen states, for the establishment of universities, prior to 1854. This may appear a most startling announcement; but we are informed by the Secretary of the Interior that the United States still possess *one thousand million of acres yet undisposed of!* When we consider this enormous quantity of uncultivated land, and the energy of the people of America, we can scarcely anticipate anything short of a rapid increase in the

soil's productions. A few years of scientific research, aided by the discoveries of modern science, will, in our opinion, double the produce of the American soil.

Although steady importations of foreign wheat and flour have taken place, there has been rather more firmness in the demand for wheat; and in some instances fine qualities have produced a trifle more money. Apparently, however, present quotations are not safe, because the inland navigation in the United States is re-opened, and heavy shipments of wheat have been commenced from the Lower Baltic ports. Everywhere, great abundance exists. In this country there is, we believe, more wheat on hand than has been almost ever known at any corresponding period of the year; and in America the supply is, according to all accounts, enormous. No doubt the surplus supply of the world will be forwarded to us; and no doubt the quantity will be in excess of our wants. Under these circumstances, speculation is out of the question; and we are somewhat apprehensive that the shipping-houses on the continent, most of whom have continued to force sales ex ship for many months past, will determine to sell on arrival, to the prejudice of the English farmer. The present returns upon the entire crop of last year, however, are more satisfactory than might appear at first sight. We must not forget that the yield has turned out very large; that the condition of the wheats is first-rate; and that a large portion of the arrivals from the North of Europe is inferior in quality; hence, a wide difference exists in prices, and that difference is certainly in favour of English qualities; still prices are low—lower indeed than could be desired; but, at the same time, the total return in money to the home growers, taking into account the comparatively high value of barley and other spring corn, is somewhat in excess of former periods of great depression in the trade, the result of overwhelming importations from abroad.

For barley, oats, beans, and peas there has been a steady, though not to say active, demand, at fair average quotations. Throughout the continent extensive supplies remain on hand; and we have every reason to anticipate unusually large importations during the remainder of the season.

Good and sound potatoes have now become exceedingly scarce; prices have consequently advanced. Inferior parcels have sold heavily, at drooping currencies. The importations from the continent have nearly ceased.

The wool trade has been in a most inactive state throughout the month; and at the colonial sales prices have given way 1d. to 2d. per lb. English wool, however, has become rather firmer in price than it was at the commencement of the month. The total importations of foreign and colonial wool into England during the first four months of the year were 122,382 bales, against 139,070 bales in the corresponding period last year. This deficiency has since been more than made good by the arrival of 40,000 bales in the month just concluded.

In Ireland and Scotland agriculture has made satisfactory progress; and the fluctuations in the value of grain have been trifling. Fat stock has, for the most part, realized fair quotations; and the supplies forwarded to England have been quite equal to many former seasons.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that the supplies of live stock on offer in the Metropolitan Market have been only moderate for the time of year, little or no improvement has taken place in the general demand, compared with the previous month. However, prices generally have ruled steady. As regards the condition of the beasts and sheep brought forward, we may observe that it has been fully equal to most corresponding periods of the year. The dead weights have, too, fully come up to previous estimates. These are important matters in connexion with the production of live stock. In the first place they prove that grazing has continued to hold its high position; and, in the second, that the supply of meat is increasing. There may be a great difference of opinion on this latter point; but no one who has narrowly watched the progress of agriculture, and who has carefully observed the various changes which have presented themselves during the last ten years, will deny that our enormous consumption of animal food is now easily met by the home producers. The depressed state of the trade and commerce of the country has, no doubt, caused less activity in the cattle trade; but we believe that there is now what may be fairly termed an abundance of fat stock in nearly every district in England. High prices during the past year, and the absence of disease amongst the cattle, have produced a result both important and gratifying. In many former years, owing to the scarcity of food about this period, large numbers of beasts and sheep have been forced for sale in little less than a half-fat state. Such, however, is not the case at present, owing to an abundance of hay on most farms, and to the rapid extension of the root-crop system. But with all these favourable features, it must be admitted that grazing has become rather an unprofitable business, arising from the unusually high prices paid for store animals during nearly the whole of 1857. The present moderate rates at which fat stock is selling may, however, serve as a wholesome check to what may be termed high speculative prices for store stock, even of a first-class character. If we trace the course of the cattle trade through a series of years, we shall find that high prices almost invariably lead to a decline in the consumption; indeed, place the actual necessaries of life beyond the reach of the great consuming classes, this result is in no way surprising: hence, we argue that moderately high prices are the safest basis upon which to conduct both the live and dead trade.

We have again to notice very moderate importations of foreign stock, notwithstanding that the value of meat in France has had a drooping tendency, and that the drain upon the resources of Holland for French consumption has become less excessive. We may remark likewise that the general condition of the beasts and sheep imported has fallen off, compared with many previous months. The future arrivals of stock from Holland are not likely to increase, for the all-important reason that the supply in the country has fallen off, and that our prices show no margin of profit on imports.

The following supplies have arrived in the metropolis during the month:—

Beasts	1,118	head.
Sheep	3,931	,,
Lambs	135	,,
Calves	1,461	,,
Pigs	13	,,
Total	6,708	,,
Same time in 1857	7,243	,,
,, 1856	3,556	,,
,, 1855	7,103	,,
,, 1854	4,708	,,
,, 1853	13,007	,,
,, 1852	8,506	,,
,, 1851	19,214	,,

The total supplies of home and foreign stock exhibited in the Great Metropolitan Market have been as under:—

Beasts	18,741	head.
Cows	480	,,
Sheep and lambs	115,886	,,
Calves	1,671	,,
Pigs	2,760	,,

COMPARISON OF SUPPLIES.

May.	Beasts.	Cows.	Sheep and Lambs.	Calves.	Pigs.
1857....	18,722	450	104,990	1,415	2,530
1856....	18,995	495	119,640	1,260	2,545
1855....	19,847	410	113,600	2,470	2,590
1854....	20,831	576	124,824	2,146	2,435

Last month 12,850 Scots and shorthorns came to hand from Norfolk, Suffolk, Essex, and Cambridgeshire; 2,500 of various breeds from other parts of England; 497 Scots from Scotland; and 208 oxen, &c., from Ireland, *via* Liverpool.

Beef has sold at from 3s. to 4s. 6d.; mutton, out of the wool, 3s. 2d. to 4s. 6d.; lamb, 5s. 8d. to 7s.; veal, 4s. to 5s. 4d.; and pork, 3s. 2d. to 4s. 4d. per 8 lbs. to sink the offal.

COMPARISON OF PRICES.

Newgate and Leadenhall have been seasonably well supplied with both town and country-killed meat. From Scotland the arrivals have been on a very liberal scale. A steady business has been transacted and prices have ruled as follows:—Beef, from 3s. to 4s.; mutton, 3s. 2d. to 4s. 4d.; lamb, 5s. 4d. to 6s. 6d.; veal, 3s. 8d. to 4s. 6d.; pork, 3s. to 4s. 4d. per 8lbs., by the carcase.

HERTFORDSHIRE (SOUTH.)

We cannot call to mind a season when the country has looked more beautiful, and the various crops more promising for a plant than they do this spring. Wheat is particularly well spoken of, good fields being the rule, and indifferent fields the exception. The tillage for spring corn has been completed under most favourable circumstances, the turnip sheep having "poached" the land less during the past winter than for many previous years; consequently barley and oats, which love a fine seed-bed, have come up strong and healthy, and generally a full plant. A few complaints of wire-worm have been prevalent in the past week. We suggest to our friends that they should *poison* these pests, as the best means of checking them. We do not mean by this that farmers should purchase any of the thousand-and-one nostrums they are solicited to buy by "agents" of every denomination; but we mean that a considerable portion of the crop of swedes or other turnips should be eaten where it is grown, that the sheep should have a little corn or linseed-cake with clover-chaff in addition, and by this means check the progress of the wire-worm under the ground, and force the corn rapidly out of the ground. Winter beans have borne the easterly winds well, and on clean land promise for a good crop. Spring beans have set well; but in many places are growing on foul land, which can never pay. It always gives us pleasure to find a farmer forward with the hoeing of his beans, and many fields are now being hoed for the second time. We regret to add that other fields are yet strangers to the hoe, and probably will receive little attention until the cleaning of the mangold crop, preparation for turnip-sowing, and other pressing matters, puzzle the farmer; who, in despair, turns some tegs into his bean-field to pick out the rank weeds—a practice we cannot admire or recommend. Mangolds have been extensively planted, and in various ways; some preferring the ridge-cultivation, others the flat (after deep-ploughing, or subsoiling). On strong soils, complaints are general that the land works unkindly for mangold-sowing, and our own clod-crusher is out on a mission to reduce a neighbour's stubble-soil. We do not care to advise our friend, who is somewhat hasty in temper if not in business, and might take it amiss; but we seriously think that if he thoroughly cleaned and ridged the land in the autumn, intended for mangold, and simply had to fork out odd roots of twitch, &c., cart on his manure, and split his ridges in the spring, he would not so often require our crusher. The store of mangold is large and very good: indeed we have never known a better season for winter-food in this part of England, and we were no little astonished, when on a visit in the north of Lincolnshire, in March last, to find a few acres of swedes had been sold by auction, at £14 per acre, at that time—a ha'penny each for the turnips, as my informant assured me. Breeding and store cattle are now being turned out to grass, the sharp frosts having kept stock in the yards for the night a little later than usual. Store sheep maintain their price, in spite of the fall in wool and mutton; and at Hemel Hempstead fair, on Thursday last, sellers preferred taking their sheep home again to submitting to lower prices. Our stall-fed beef is pretty well cleared out, and when the demand for lamb abates, we shall not be surprised at a rise in mutton. Some fine rains during the last twenty-four hours have been highly beneficial to corn and grass. Succeeded by warm nights, we may reasonably anticipate good crops of mowing-grass, the meadow-lands having been well dressed with dung, and eaten down close during the past winter. Wheat continues a wretched trade, with no prospect of amendment. Other descriptions of corn realize a fair price. The splendid weather for farming-operations with which we have been favoured for the last twenty months must be a source of thankfulness to the English farmer, and we do not envy the disposition of him who complains, but think he had better take the first outward-bound ship, and compare his native clime with far-away lands, rich in gold and discomfort.—May 15.

DERBYSHIRE.

We have now come to a most delightful period of the year. The aspect of the county pleases the eye, even to the mountain-top, with its verdant hue. We have plenty of grass; and stock is generally laid on to graze. Potato-planting is now the chief employment, and a considerable breadth is being put in. There is plenty of seed found, and the value of such has receded. That mysterious thing called potato-disease, because we suppose there is nothing else to designate it by, seems to lose its virulence as the winter leaves us, and now we hear little of it, and see less. We have had a splendid seed-time, and all kinds of spring cereal crops have a good appearance. The wheat-plant is as fine as we can desire, and the quantity of yellow blades, generally termed by the practical man *Maying*, is much less than we expected to have seen; and as that appearance or non-appearance is considered to augur well or ill for the future, we hope that future is fraught with abundance. Farm-work is very forward; and turnip-drilling has in some districts already commenced. The demand for what is generally termed artificial manures continues unabated: in some instances they realize more money, while most other things in connection with farming are of less value. We imagine as a farming community we are going to the extreme in this respect; we first exhaust the soil by taking our culmiferous crops, and then as a consequence are obliged to purchase those nitrogenous—dearest of manures, at too much haphazard. Would it not be wiser to curtail our cropping, and reduce our need of such extraneous aid? For instance, instead of two white crops between what is termed the fallow, would it not be better to seed down with rape after turnips? thus having three years for pasture on a five-course system, one corn-crop, and one turnip-crop. We leave this hint with our readers; but we put it in practice, and keep up the stamina of the soil. Our spring markets and fairs for stock have been depressed, and everything has given way in value. Our corn markets have for depression kept pace with the metropolitan report, and we have of wheat now a good home-supply on hand. Many farmers refused to sell, last autumn, because they considered prices were not remunerative. The comparatively high value of grain for several years past had unfitted them as a body for so sudden a reduction; and the majority held on and on, until now their case becomes almost hopeless, and a good quantity of their corn, wheat especially, has yet to

be brought to market; hence the prospect of coming prices. The labour market is easier, and good skilled hands are more readily met with: wages for adult labourers from 12s. to 15s. per week. We trust, with a better supply of men, agricultural improvements will still further advance, for if the principle be sound of buying in the cheapest and selling in the dearest market, then he must be the wisest man who employs the most men when they are obtainable at the least rate.—May 12.

ISLE OF ELY.

If we remember correctly, when our last report left us the weather was severely cold, with sharp frosty nights; but we believe, ere it appeared in print, the weather had suddenly changed, and we had some very fine warm days, and were willing to hope spring had really come. But we were sadly disappointed; for May opened upon us with cold nipping winds blowing chiefly from the north and north-east, and the days were nearly all followed by frosty nights. We also had some cold rains at the beginning of the month, and it was not until the last few days that milder weather set in. The wind then veered to the S.S.W., and has since been blowing softly, and vegetation is rapidly progressing. We have also had some very fruitful showers, with thunder and gleaming sunshine. We cannot speak so favourably of the appearance of the growing wheat as we did a month ago. The cold rains which fell early in May have made some of the cold tenacious clay soils present a yellow and sickly hue, which is always a bad omen at this season of the year, and bespeaks a small ear and a lighter yield. On the black fen soils the weather has produced an opposite effect, having made the wheats grow *soft* and *flaggy*; and we see many fields where a good deal is *laid* already, and looks yellow and weak in the stem. Many of our Fen farmers are sending men with hooks and scythes to cut off some of the heavy flag, thereby enabling the plant to rise again. At present these soils look much more like yielding a heavy crop of straw than a large produce of grain. But it is always difficult to predict in May what will be the state of the crop in August, as the changes in a crop of wheat whilst growing are frequently so sudden and so great that we never know the result until it is actually attained. The cold rains and frosty nights have seriously injured the oat crop, and in the Fens generally it is now looking badly. The wireworm has committed fearful ravages in some instances, and several fields either have been or must be *resown*. On the high lands the prospect is better. Beans generally are strong and look well. Mangel sowing is nearly completed. The rains and warmer winds of the last few days are highly favourable. Grass keeping is improving. Our pastures are now good, but we hear of complaints in some counties of grass being very scarce. Store cattle are lower and slow to sell, we conceive in consequence of the shortness of keeping in other localities. Beef is slightly better to sell. Store sheep are dearer; mutton maintains its value. Pork is still a heavy trade, and store pigs a little dearer. The wheat trade fluctuates slightly, most weeks either a shilling up or down. Supplies are not heavy, and the weather and appearance of the growing crops will now exert considerable influence upon prices.—May 18.

SUFFOLK.

Within the past few days we have had a change of wind from N. and N.E. to S. and S.W., and the consequent increased temperature combined with refreshing showers of rain have greatly improved the appearance of vegetation generally in the county. The wheats for the most part look promising, and it is the opinion of many that the crop never presented a better appearance; but we observe in some cases a too perpendicular ascent of the stem, and a want of tillering. The coldness of the weather, and especially the frosts each night, have naturally retarded the growth of the barley, and on the stiff clay soils the influence has been particularly remarked; but since the late refreshing showers a burst of luxuriancy has been the result, and the strength of the stem and the curliness of the blade give indication of an abundant yield. Owing to the winter's frost so well pulverizing the land prepared for beans, the plants are strong and luxuriant. The peas look equally well. The mangold wurtzel seed has been put in very satisfactorily, and the plant is generally up, with a dark-green thrifty appearance. The cultivation of swedes has greatly diminished, owing to the superiority of the mangold crop. Some are already sown and up, whilst others are daily being drilled. Stock farmers have been much pressed for feed, and the chief reliance has been the mangold wurtzel crop, which yearly increases its reputation: even many flocks have lived mainly on this root; and where a bite of green food has been given in addition, the ewes and lambs have thriven well. Beasts have been put on a shorter allowance of food, or they are sent early to market, but so unsatisfactory have been the returns, that the graziers' losses are considerable, and men reluctantly submit to such heavy sacrifices.—May 18.

CUMBERLAND.

The weather during the spring months has been as favourable for cleaning and preparing the land for the reception of the seed as could well have been desired. It was sufficiently dry for the operation of pulverizing and cleaning the land, and yet was supplied with sufficient moisture by the showers of rain that occasionally fell to prevent it from baking with drought or stunting vegetation by want of moisture. On the afternoon of Friday, the 14th inst., the east of Cumberland was visited by a good deal of thunder, heavy showers of rain falling here and there—in some places mixed with a considerable quantity of hailstones. This was followed, on the evening and night of Saturday, with a considerable fall of rain, which has continued at intervals up to the present time; and to-day and yesterday it has been blowing—and continues to blow—something like a hurricane. A rather large breadth of potatoes has again been planted under favourable circumstances, so far as the weather and state of the land are concerned, but the result will depend upon the after-part of the season being wet or dry. Mangel wurzel has been extensively sown this year. The importance of this valuable root is rapidly becoming better understood and appreciated. The sowing of swede turnips has been retarded these last few days, in consequence of the land being too wet from the recent rains to allow of its being properly finished up; the consequence is that much fewer turnips have been got in than might otherwise have been the case. Wheat, as it has done all the winter, is looking very well—perhaps, too gross and thick upon the ground, with a too-luxuriant blade, which, should it turn out a damp summer, may be very prejudicial to the crop. Oats were got in favourably and are going on well, with little harm from their old enemy the grub. Barley, too, was got in well, and is so far promising. Grass lands received a considerable check from the severe weather in the early part of March, with some cold east winds in April; but the fields rapidly recovered their green hue, and have lately been full of grass. Should the present wet weather continue some time longer, it will give a chance of a good crop of hay, as, according to the old adage,

"A wet May
Gives plenty of hay."

The grain market, especially wheat, continues much depressed, without any prospect of much improvement. Oats and barley, though selling at a comparatively better price than wheat, have been lower during the last two or three weeks. Beef and mutton are both lower than some time ago. Penrith fair, held on the 23rd April for sheep and the 24th for cattle, being the first important fair in the district, is a criterion to judge by of the value of cattle. At this fair cattle and sheep for grazing sold lower than expected, consequently the dealers, at least many of them, would realize a loss instead of a profit, having picked them up in the country at a price beyond what the market would afford. Although prices are considerably lower than last year, they are still high when compared with some former years. As regards sheep, the decreased price of wool has assisted materially to reduce their value, and yet wool has often been known to be sold at a less price than it is likely to be this year. There is no reason for farmers to despond: the price of agricultural produce is going through one of those periodical times of depression which have regularly occurred in the course of from eight to ten years. If any have reason to fear, it will be those who have lately taken their farms at an in-

creased rent in proportion to the late high price of agricultural produce, under an impression that these prices would be permanent.—May 19.

EDINBURGHSHIRE.

Seldom have we to announce such favourable weather for field operations during the all-important months of spring. At short intervals we experienced intense frosts, the thermometer ranging occasionally from 10 to 15 degrees below the freezing point. Less damage has been done to the young wheat and seedling grasses than we have seen at a higher temperature. This is no doubt attributable to the extensive drainage which has been carried on for many years past, coupled with the extreme dryness of the soil during winter and spring. As a fact, only 5.50 inches of rain has fallen, at a water-gauge kept in the highest district of the county. Wheat appears of average breadth, and the fields everywhere look vigorous and well planted. Barley and oats, along the sea-board and in the finer districts, look healthy in the extreme; while in the middle and alpine districts, they have of late assumed a rather sickly appearance, evidently suffering for want of rain. Beans appear more extensively sown than formerly, and undergoing the process of cleaning by horse and manual labour. In the lower districts potato planting was commenced before the sowing of spring corn, which is now under horse and hand cultivation. High as the price of seed has ranged, and the heavy loss sustained last year, a full average extent of ground appears planted. The cultivation of this invaluable root has become somewhat resembling a "lottery," some obtaining a handsome prize, while the majority have to put up with a small show, and many blanks entirely. A few samples are still pitched in our weekly market, and prices receding. Sowing of Swedish turnips has been prosecuted vigorously during the month of May, and doubts are entertained that the nipping frosts may have injured those brairded as likely to run to seed, ice being of considerable thickness in the standing pools in May. The wind has now veered to the south-west, with frequent showers, which will have the beneficial effect of pushing forward a rapid vegetation, affording a full and sweet bite for all kinds of bestial. The extent of land under turnips is annually increasing, and from the quantity manured in autumn abridges greatly the labour when portable manure is only necessary in spring. Cattle markets are unusually large for the season, 1,206 being exhibited on the Edin stance on the 12th instant; finest quality was reduced in price, while secondary and inferior could scarcely be turned into money: 256 grazing cattle appeared, and found ready buyers at high rates: milk cows numbered 139, many of excellent quality and in good demand: of sheep 4,997 were penned, being 900 more than last week; a considerable number were hoggs for grass; for both sorts a good demand was experienced at extreme rates—blackfaced mutton (in the wool) from 8d. to 8½d., whitefaced 6½d. to 8d. per lb.: pigs numbered 393 —young ones from 7s. to 10s. a head; grunters from three to four months old cheap, and difficult to dispose of. Grain markets are large for the season of the year; wheat meets a sluggish sale at reduced rates, barley in limited supply and meets a dull sale, oats brought freely to market (1,464 qrs.) with a good demand and former rates fully supported. Wool growers have had the best of it for years past, prices being unusually high. Since the crisis in November last a decline of fully 6d. per lb. has been experienced. Seedling grasses seem well planted; the breadth appears less than in bygone years; the open winter and spring made speculations in hay anything but remunerative, and the prevalence of depasturing young grass with sheep greatly abridges the hay crop. English portable thrashing machines have been busily employed in cleaning out the barnyards, being found admirably adapted for leaving the straw in a fitting state for thatch. This has been long felt as a great desideratum in our Scotch machines, calling loud for some improvement in this respect. Wheat-growing farmers have suffered severely from the unfavourable state of the weather during the last harvest, and large quantities are unfit for baking, and have to be disposed of for distilling and feeding purposes. The mania for farms still continues, and when advertised the puzzle is not to get a tenant, but how to select one. The farmer class are frequently "outbid" by individuals who have saved money in other occupations, their professed object being country air and residence. Money still appears to be their object, and after feeling a few years' disappointment, frequently leave in disgust. Draining operations are somewhat abridged; and no wonder, seeing to what extent it has been carried on for years. Still we have no redundant population, and willing hands find ready employment at fair wages. While writing, the protracted drought has at length been changed into a drenching rain. The streams are much increased. The change will be gladly appreciated by all—the agriculturist in fostering vegetation, which has been lingering; the manufacturer in adding to his water power; the compensation ponds throughout the county being lower than they have been for a number of years; draw wells have been dried up, and recourse is had to the "pitcher" and "can" for supply at the nearest stream.—May 20.

WEALD OF KENT.

Since our last report we have experienced some very sudden changes in the temperature of the atmosphere, with piercing easterly winds, which have tended to slacken the growth of the wheat plant to a certain extent. On stiff clay soils slackness of plant is complained of; but on good land this is not the case, and it only needs warm weather to succeed the showers which we have lately been favoured with: we might then calculate upon a luxuriant appearance. The pastures are very bare, which cannot be wondered at, with such cold weather. Beans and peas that were sown early are looking well for the most part. Barley and oats not so well as we could wish, still, with milder weather, we shall not have much room for complaint. The price of Lent corn has not varied much since our last, with the exception of oats, which are very scarce in this neighbourhood, and are selling at high prices compared with other grain. The hop plantation is now receiving considerable attention; tying has commenced; the bine does not look healthy, and is much infested with flea; a full crop this year would prove very injurious, looking at the immense quantity in the hands of growers, speculators, and factors. Great credit is due to the members for East Sussex, who have by their assiduous exertions obtained from the Chancellor of the Exchequer the postponement of the duty, which is a very great relief to a large body of the planters; had the full payment been insisted on, immense sacrifice must have been made to enable them to have met the demands.—May 19th.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

BOGBAIN MARKET.—A good show of cattle of every description. There were no fat sheep, but plenty hoggs and shot lambs. The sheep were not in great demand, especially the blackfaced. Prices, however, were in advance of those of last market. Cattle were fully 5 per cent. up. Highland queys, two-year-olds, were sold at £4 15s. A Highland bull, a two-year-old, fetched £10. The market was very brisk.

BUNGAY FAIR was the largest as to attendance of company and the show of stock, especially neat stock, which has been held for many years. Business was dull, owing to the shortness of feed; but as the time approached for driving off the unsold, the demand became much brisker, and a fair amount of trade was done in fat stock at from 6s. 6d. to 7s. per stone. Fresh stock also was in demand, and sold freely at a slight reduction upon the London quotations. Several good horses were exhibited.

CASTLETON FAIR.—The quantity of stock offered was small, and the trade very slack. Beef, about 11s. per

score; heifers and calves, from £10 10s. to £13 10s. each; yearlings, £5 each; two-year-olds, £6 10s. to £7 10s. each. A few sheep offered; but few sales, if any, were made. The best store pigs at from 25s. to 35s. each; small, from 4s. 6d. to 8s. 6d. each; sows, with their young pigs, £4 to £4 5s. each.

DUNSE HOGG TRYST.—The supply was fully an average one. The demand was good, and a great many sales were made. The following were the current prices: Cheviots from 16s. to 22s.; cross-bred from 26s. to 34s.; a lot of half-bred sold at 40s. There were a number of stirks in the market, which were selling at from £6 to £10 each.

DUNSMUIR TRYST.—There was a large attendance of farmers, dealers, and others, and there was a considerable quantity of stock on the ground, which found ready purchasers on good terms. Prices of prime fat were 9s., down to 8s., according to quality. A very excellent lot of queys, considered the best in the market, were sold by Mr. Webster, Witston, to Mr. Welsh, Tillytoghills, at £16 16s., which was considered about 9s. per stone; and several other lots were sold at the same price. There was a fair supply of grazing cattle, which were for the most part disposed of fully above that figure. The other descriptions of cattle met a ready sale at reasonable prices; and, on the whole, the market was good.

EXETER FAIR.—The attendance of agriculturists was good; and the number of beasts driven in was rather above the average. The trade, however, was not brisk, and a great deal remained unsold. Best beef fetched from 9s. to 10s. per score. Barreners, best quality, 6s. 6d. to 8s. per score; cows and calves, £10 to £16. There was a good supply of store sheep, and prices ranged from 30s. to 38s. each.

GLOUCESTER MONTHLY CATTLE MARKET.—An abundance of beef, mutton, and lamb, and purchasers were well supplied with every description of stock. Beef ruled from 6d. to 6¼d.; mutton, 6d. to 6½d.; lamb, 8d. to 8½d. per lb.

HAY FAIR was a full one of stock. Young steers and fresh barrens were in good demand, but owing to the want of grass in the midland counties the dealers were not willing to speculate for fresh bullocks. Good cart horses were readily sold at very remunerative prices; there were but few good hacks, and for them prices were lower.

HALTWHISTLE FAIR.—Shorthorn cows, milking or in-calf, made from £15 to £19; stirks, £7 10s. to £9. Galloway cows, in milk or about dropping a calf, from £12 to £15—some prime ones a few pounds over the last figure; heifers, calved or in calf, from £11 to £13; stirks, £5 to £6 10s.; two-year-old bullocks or heifers, from £7 10s. to £8 10s. Irish heifers, £5 to £7. Galloway cows, not in milk, ready for the grazier, £9 10s. to £11 10s. There was only a small show of sheep. Blackfaced hoggs ranged from 16s. to 19s.; Leicester hoggs, from 23s. to 27s.; Cheviot ewes, with lambs at their feet, from 35s. to 38s. a couple. The Leicester hogs were also good in quality. There were 23 cartloads of pigs, of average quality, which sold well. Pigs six or seven weeks old, from 11s. to 15s.; seven to nine weeks, 15s. to 19s. and 20s.

HEREFORD FAIR.—Fat cows sold readily at 7d. per lb. for all on offer; fresh barrens and young grazing stock also commanded a ready sale, but lean steers and cows with calves, of which there were a large number in the market, hung on hand rather heavily, owing to the lateness of the season and the high price of keep in some districts. There was a large supply of sheep in and out of the wool. Fat wethers, and all ovine stock fit for the knife, readily realized 7s. per stone in the wool, with a proportionate reduction in others for the absence of the fleeces. Ewes with lambs ruled about 46s. to 48s. per couple; a few very prime ones fetched over 50s. Lambs sold singly to the butchers from £1 to £1 8s., according to age and fatness. Store pigs were numerous, and changed hands with celerity, at prices fully equal to those which have lately been obtained. There was a large horse fair; but besides a limited number of useful hacks, which met a ready demand, the majority of horses on offer were for heavy draught purposes; these also sold extremely well, according to age, condition, and quality.

HOLBEACH FAIR.—A large show of horses; many of them very middling and inferior, but for anything good (and there was a fair supply of these), there was a brisk demand, and rather better prices were obtained than have prevailed of late, the attendance of buyers being very great.

IPSWICH FAIR.—The show of cattle and sheep was larger than seen for years. Owing to the recent flatness in the Metropolitan Market, trade opened dull and continued heavy throughout the day. Fat beasts fetched from 6s. 6d. to 7s. per stone—store beasts from 3s. to 3s. 6d. per stone what they will weigh when fat. Hoggets from 32s. to 48s.; fat lambs, 25s.; stores, 13s. to 22s.; couple from £2 2s. to £3; stock lambs from 14s. to 24s. Of cart horses and colts, there was about an average supply.

KIDDERMINSTER FAIR.—An average supply of cows and sheep, for which there was but a moderate demand. Only the best stock fetched previous prices, they generally being at lower rates; mutton scarcely realizing 6½d., and beef 6d. per lb. A good show of pigs, which sold at rather less than of late.

KNIGHTON FAIR was very numerously supplied. Prices were obtained much superior to those of any neighbouring fairs. Mutton brought 6½d. to 7d.; beef, 5½d. to 6d. Store animals sold well. Wool fetched 1s. to 1s. 3d. per lb.

LEDBURY FAIR.—A goodly number of excellent fat cattle, including some fine oxen. The supply of sheep was also tolerably good, more especially stores, which did not sell quite so well as at former fairs. Of store cattle also the supply was larger than the demand, and upon all kinds of stock a slight reduction in price had to be made before sales could be effected. The fair was also tolerably well supplied with store pigs. The fat stock was nearly all disposed of. Fat cows, 6d. to 6¾d. per lb.; ditto sheep, 6d. to 6½d., and a few choice ones a shade dearer; store sheep, 26s. to 38s. each; ditto pigs, 20s. to 40s. each.

LINCOLN SHEEP MARKET.—A fair, though by no means a large show of sheep, and prices were fully 1s. to 2s. per head lower than the high rates realized this day fortnight.

MUIR OF ORD MARKET.—The show of cattle was above the average of May; there was also an extensive show of hoggs. The prices of sheep, that is hoggs and lambs, were slightly above those of last market, and a good many sales took place, buyers and sellers seeming equally eager to do business. In cattle there was an advance from the price of last market, varying from 5 to 10 per cent.; or, as it was loosely said on the market, of £1 10s. on the average stock. The prices were therefore not very much below those of May, 1857—very different from what all but the most sanguine calculators had looked forward to. The heavy rains which have lately fallen all over the north have given farmers assurance of a fair grass crop, and increased the upward tendency in prices commenced at the April market on the Muir. There were a good many south-country dealers present. The market was very brisk. There was not much done in the horse market.

NEWARK FAIR. — A large show of beasts and sheep. The former sold readily at advanced prices. The best stores for summer grazing made from £12 to £14 each. Milkers also realized good figures. Sheep were disposed of at liberal prices, but did not sell quite so well as at the previous market. Hogs 42s. to 45s. each. The horse fair was large, but it contained many animals of an inferior order. The better sort of horses, of which there was a tolerable sprinkling, were very soon disposed of.

NEWTON STEWART MONTHLY CATTLE MARKET.—Sales were very brisk, and the cattle of each class (stirks and two-year-olds) brought good prices. Whether from the prospect of a plentiful supply of grass, or other causes, the prices obtained were fully beyond what had been anticipated, and if this one be taken as an earnest of our future markets during the season, our farmers and graziers will certainly be well remunerated.

STRATFORD-ON-AVON FAIR. — The number of fat cattle was small; the supply of stores was good; stirks, &c., making from £4 to £10 each; cows with their calves were plentiful, and met with a ready sale from £14 to £22 together; barrens brought from £10 to £18; calves, weaners, from 30s. to 50s.; sucklers, from 25s. to 35s. each. There was a brisk demand for sheep, of which there were penned about 3,000, besides lambs of first-rate quality, and there were several fine lots of sheep shown in the wool. They brought high prices. Beef, 5d. to 6d. per lb.; mutton, 5½d. to 7½d.; veal, 6½d. to 7½d.; lamb, 7½d. to 8½d.; pork, 6½d.; fat bacon pigs, 8s. 6d.

to 9s. per score. There were very few horses shown, though much inquired after. Decent animals brought high prices.

STURMINSTER FAIR.—A good supply of the various descriptions of stock, heifers and calves meeting with a brisk and ready sale, but the prices for fat stock were on the decline, and business in this way moved very slowly. The trade in barreners was very dull.

TEWKESBURY FAIR was but thinly attended, and there was a short supply of stock. The sale of beef was flat, at from 5d. to 6d.; mutton met with a better sale at from 5½d. to 7d. per lb.

TOLLER DOWN FAIR.—The attendance was not so large as usual, in consequence of the rough weather. The supply of sheep also was not very extensive, but there was a good demand, and they sold well. Very high prices were asked for horned ewes, and horned lambs fetched from 22s. to 26s. per head. A large show of cow stock, but of a rather inferior description. Among the horses were some very promising animals, both cart and hack.

WELLS FAIR was well attended by dealers and buyers. The show of cattle was not very large, and consisted chiefly of heifer stock. There was a good number of sheep penned, many of them shorn. Of pigs, also, there was a good show. Trade was pretty brisk.

WISBECH FAIR.—A large supply of horses and good animals, not a few of which realized good prices. A great many bullocks were also brought to town, and for which large sums were given. The sheep were about the average price.

WOODBRIDGE FAIR.—A very large attendance, and a good supply of stock. Good heifers and calves were in demand, and those offered sold readily at high prices. Barreners were also inquired after, and met a ready market.

WOOLER FAIR.—Bred hoggs brought from 36s. to 43s., half-breds from 27s. to 36s., and Cheviots from 22s. to 26s. Ewes, of which there were a good many small lots, were bringing readily, for ewes with single lambs, 50s., and with double lambs 60s., some few of the latter as high as 67s. There was a small show of grazing cattle, but what there was brought good prices, considerably higher than they have been at the sales in the neighbourhood. Good two-year-olds were bringing from £10 to £13. The number of cows was larger than usual, but being principally old cows, there was a dull sale amongst them, except for two and three-year-old queys, calved and to calve, which were quickly bought up at from £10 to £14.

IRISH FAIRS.—MULTIFARNHAM.—Prime beef was scarce, and the best was quoted from 56s. to 58s. per cwt. Store cattle were plentiful, and numbers were in first rate condition, but purchasers seemed particularly cautious in buying, so that sellers were obliged to submit to a reduction in prices. Three-year-old heifers brought from £10 to £13 10s. each; two-year-olds, £8 to £10 10s., and yearlings from £2 15s. to £4 10s. Good dairy cows were in active demand at full prices. Pigs were also brisk, and good Bacon sorts brought from 40s. to 44s. per cwt. Stores in good demand, at fair prices. BALLIBAY was abundantly supplied with cattle of all kinds, except fat cattle; buying was exceedingly brisk, and prices, except for young stock, which were rather dearer than usual, were equal to those obtained this month at neighbouring fairs. The demand for pigs was dull, both bacon and pork being sensibly lower.—CAVAN: A great many cattle were left unsold, and prices were on the decline. For sheep the demand was very brisk, and all sold. Pork was cheaper than at late markets.—BAILIEBOROUGH: All descriptions of cattle were plentiful, except beef. Few, if any animals, remained unsold, and everything maintained current prices.—HILLSBOROUGH was pretty well supplied with stock, excepting that beef was rather scarce. Strippers plentiful, and prices looking down. Springers in good demand at 10*l.* to 18*l.* each. The prices of store cattle were tending downwards. Two-year-old heifers sold at prices ranging from 7*l.* to 10*l.* 10s.; yearlings from 3*l.* to 7*l.* 10s. Pigs were very plentiful, and prices somewhat higher than during the past month. The supply of horses was smaller than usual at this fair; good animals were in demand at from 20*l.* to 40*l.* each.

CARMARTHEN BUTTER MARKET, (Saturday last.)—A better supply of good fresh grass Butter brought to our market this day, and our farmers freely obtained 98s. per cwt. for fair average quality. This drop in the market will give rise to an active demand, and we doubt any further marked reduction in value for the present.

CHIPPENHAM.—Good cheese had a ready sale. Old broad doubles, 58s. to 63s.; new, 56s. to 59s.; prime Cheddar, 60s. to 68s.; thin, 38s. to 50s.; skim, 18s. to 28s. per cwt.

GLASGOW.—There were seven carts shown in the bazaar, and 13 tons passed through the weigh-house scales. Sales were slow, and lower prices taken. Prime early-made, 48s. to 52s.; late-made and inferior, 42s. to 45s.; new skim, 23s. to 24s. per cwt.

GLOUCESTER.—The quantity of cheese pitched was small, and the quality generally inferior. The prices obtained were: Skims 25s. to 28s., second 40s. to 46s. No best quality on offer.

YEOVIL.—Best cheese 56s. to 70s., household 20s. to 38s. per cwt. A good business was done.

ENGLISH BUTTER MARKET.

LONDON, MONDAY, May 24.—Since our last report we have had a considerable fall in the price of all sorts of Butter, which now leaves the market pretty steady

Dorset, fine	102s. to 104s. per cwt.
Ditto, middling	90s. to 96s. „
Fresh.....	9s. to 13s. per dozen.

POTATO MARKETS.

SOUTHWARK, WATERSIDE, MONDAY, May 24.—Since our last report our supplies from foreign ports have been light, but coastwise rather more liberal. There is a considerable advance to note in prices of some descriptions, as the trade has been more active, at the following quotations:

Yorkshire Regents.....	140s. to 190s. per ton.
Lincolnshire do.....	140s. to 160s. „
Dunbar reds	80s. to 90s. „
Perth, Fife, and Forfar Regents	120s. to 140s. „
Ditto ditto reds	80s. to 90s. „
French whitea	40s. to 110s. „
Belgian do.....	40s. to 70s. „
Ditto reds	80s. to 120s „

BOROUGH AND SPITALFIELDS.

LONDON, MONDAY, May 24.—The arrivals of home-grown potatoes continue on a full average scale for the time of year. Since Monday last the imports have been confined to 150 tons from Dunkirk and 150 sacks from Antwerp. Good and fine qualities—the show of which is limited—are in fair request at full prices, but other kinds are very dull at barely late rates.

York Regents	140s. to 180s. per ton.
Kent and Essex do.....	80s. to 160s. „
Scotch	120s. to 160s. „
Do. Cups	70s. to 90s. „
Middlings	50s. to 90s. „
Lincolns	120s. to 140s. „
Foreign	50s. to 90s. „

COUNTRY POTATO MARKETS.—YORK, May 15.—Potatoes sell at 1s. per peck, and 3s. 9d. to 4s. per bushel. LEEDS, May 18.—A short supply of potatoes, which sold at 15d. to 16d. per 21 lbs. wholesale, and 16d. to 17d. retail. MALTON, May 15.—Potatoes, 1s. per peck. THIRSK, May 17.—Potatoes, 6d. to 12d. per stone. RICHMOND, May 15.—Potatoes, 4s. 8d. per bushel. SHEFFIELD, May 18.—Potatoes sell at 10s. to 18s. per load of 18 stones MANCHESTER, May 20.—Potatoes, 11s. to 19s. 6d.

PERTH POTATO TRADE.—The export of potatoes to the southern markets has been going on to a small extent, but prices still remain the same as last week. Best sorts average from 22s. to 23s. per boll, and inferior from 15s. to 16s. per ditto.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

The first half of the past month was cold and ungenial, vegetation being kept in check, and a yellow hue was spread over much of the young wheat and barley; but warm showers and fresh breezes from the west, with a good deal of sun, have materially changed the face of things for the better, the only fear now entertained arising from the too luxuriant appearance of the forward wheat on highly cultivated land. An abundance of straw and grass is now pretty certain; but without dry, sunny weather, an equal yield of wheat with last year cannot be expected. Durham and Northumberland appear exceptions to the generally strong appearance of the wheat plant, from the long prevalence of drought and cold. As respects prices, the month has shown little change; the utmost fluctuations have not exceeded 1s. per qr., and the balance of the four weeks is a slight gain.

The state of the London and general averages shows a remarkable agreement, and the steadiness of prices throughout the entire country. To place the former on a par with the latter as respects time, they must be put one week back; and by so doing, we have this result: The general averages commence at 44s. 9d., and the London included therein were 47s. 8d.; the general close at 44s. 11d., and London at 47s. 11d.; making an advance of only 2d. per qr. in the general averages, and 3d. per qr. in the London—London commencing at 2s. 11d. over the general rate, and closing at 3s. over it. This small difference accounts for the slender supplies which have come to the London market, which is, however, well provided with foreign wheat and country flour. Future prices must greatly depend on the weather; but as the rates are much below the average of the last ten years, and the quality above it, we think farmers need not force off their stocks, as a good quantity of fine old wheat must be required for mixing, and foreign markets have lately been improving. The course of the deliveries for four weeks shows that less English wheat has lately been selling than during the same period last year. Last year's sales for a month were 439,893 qrs., this year they were only 402,861 qrs.—deficiency this season 37,032 qrs. Now as the importations, including flour, this year, for four months, have greatly exceeded the first four months last year—viz., to the extent of 607,818 qrs., or about 35,700 weekly—and yet stocks of foreign in all shipping ports are small, it follows that the low prices, with an increased population, have produced a consumption not calculated on; and this is likely to continue.

The prospects of a good crop abroad are not so promising as recently. Algeria has improved by a timely fall of rain, but last year's abundance is not looked for. Spain, in some places, has been suffering from drought; and in Asia Minor this has been excessive, and quite endangered the crops. Piedmont, on the contrary, has had too much wet; and in other parts of Italy it has not been genial. France still looks well, and in the South the wheat is coming into ear. In Northern Europe there are fair appearances, and American reports are generally favourable. The continental markets have been firm, or slightly dearer. France is decidedly so, the Paris flour market having recently advanced about 2s. per sack English, from the low stocks in millers' hands; and wheat has risen 1s. 6d. per qr. The best flour was worth 31s. 9d. per sack, and wheat 42s. 6d. per qr. At Bordeaux, the price was 41s. 9d. In Belgium the range was from 43s. 9d. to 45s. 9d. for top quality. At Amsterdam, prices were 40s. 6d. to 52s. 6d. At Rotterdam fine heavy red was worth 44s. At Hambro', quotations were 40s. 6d. to 42s. 9d.; Stettin, 43s. 9d; Danzic, where large sales have been making, 41s. to 48s. for high mixed; Berlin, 42s. 3d. per qr. Navigation being resumed at Petersburg, prices for soft wheat have opened at about 40s. 6d. per qr. At Odessa, the new supplies are dropping in plentifully; the quality is well spoken of, but rates have been firm, in consequence of the clearance of previous stocks. Polish wheat was held at about 38s. 3d., Ghirka 39s. 3d. per qr. The trade at Galatz is beginning with moderate quotations, 28s. only being demanded. Sales from Varna have been made at 32s. Prices at Trieste, which had received Spanish orders, were 43s. 2d. Genoa had risen 2s. per qr., and literally nothing has resulted from the Neapolitan permission to export at a high duty. The different markets in Spain, from north to south, are firm, though lately all were expecting lower rates. At Alicante, Taganrog wheat was worth 53s. 4d.; at Seville, 55s. per qr. With the canals open, New York is getting supplies, and flour has somewhat yielded; so that a moderate export has ensued. The wheat market looked heavy, but no quantity yet pressed on holders; the last quotations

were about 48s. per qr. for the best Southern, and 42s. 6d. for Kentucky white. There is doubtless a good store in the lake ports, and the weather will influence holders there in their shipments; but with a return to monetary ease, and continuance of low rates, there seems no probability that exports will be very free.

The first Monday's wheat market in London commenced on the back of moderate supplies, both English and foreign. Kent and Essex, in the course of the morning, sent up quite an average show of samples. Factors commenced by asking higher terms, and in some instances 1s. per qr. improvement was realized, but eventually sales were made at former prices. The good attendance from the country was disappointing, holders of foreign not being able to sell at an advance, and only a small quantity was sold. The country markets throughout the week scarcely made any change in the quotations. Liverpool, on Tuesday, was unaltered, and Friday's rates there were hardly equal to the previous day.

The second Monday had better supplies, especially of foreign, a good deal of wheat being imported by millers direct. This circumstance was unfavourable to prices, notwithstanding a very small supply during the morning from Essex, and only a moderate one from Kent. For some time factors endeavoured to obtain the previous rates; but as the day wore, it was found necessary to concede fully 1s. per qr. generally; and there were offers at the Kentish stands at 1s. to 2s. per qr. less money, without an entire clearance. The business in foreign was very limited, at unaltered rates. Manchester, Hull, Boston, and Bristol markets were all rather against sellers, Newark, Spalding, Louth, and Gloucester, and several other places reporting 1s. per qr. decline; but Birmingham, being scantily supplied, was in favour of sellers, and several of the Saturday's markets were 1s. per qr. up. Liverpool, on Tuesday, was without change; but Friday was decidedly easier, both for wheat and flour.

The third Monday was less liberally supplied, the foreign not reaching to 6,000 qrs. Kent and Essex also sent up but a scanty show of samples, and factors therefore required some advance in their offers; this, though generally reported, was realized in very few instances, and for picked samples alone, the general runs not being placed at anything over the terms of the previous week. Newcastle, Hull, and the early Yorkshire markets noted no change in prices, the tone being firm. Newark, Spalding, Lynn, and Market Rasen were 1s. higher. Birmingham, Gloucester, and Bristol did not raise quotations. Liverpool, on Tuesday, had a good attendance, a large reduction being thought probable, from the liberal foreign supplies; the only fall, however, was 1d. per 70lbs. for wheat, and 6d. per sack on flour. On Friday, prices there were scarcely so good.

The fourth Monday was moderately supplied, the arrivals from Kent and Essex being limited. Early in the morning, fine parcels went off at full prices, but in the market subsequently the former rates were difficult to obtain, offers of 1s. per qr. less being refused by factors. The foreign trade was slow and unaltered. London remained unaltered to the week's close; Liverpool and several country markets quoted rather lower rates, but generally there was little difference throughout the country.

The imports into London during the first four weeks were 20,154 qrs. English and 48,763 qrs. foreign, against 28,600 qrs. English and 20,067 qrs. foreign in May, 1857. The imports into the United Kingdom for April were 383,149 qrs. wheat and 364,769 cwt. flour, against 196,278 qrs. wheat and 189,172 cwt. flour during the same month last year.

Flour during the first four Mondays in May has scarcely changed, town-made top quality remaining at the price with which the month commenced, viz., 40s. per sack. Norfolks have varied at from 30s. to 31s. per sack. The comparatively high range of prices at new York has so limited importations thence, that really fine qualities of this description have become scarce, and for this reason have rather risen in value; but French samples have been sufficiently plentiful for the dull state of trade, and have mostly left a loss to the importers, good qualities having brought only 32s. to 33s. per sack. The imports during the four weeks have been—in country sorts 68,402 sacks, in American 3,553 brls., with 9,287 sacks foreign, principally from France, against 71,448 sacks English and 3,761 brls. 110 sacks foreign in the same period last year.

The barley trade during the month has little varied, prices of the best sorts having declined with the season for malting, with very little left over fit for this purpose, so that maltsters will be entirely dependent on the growing crop for future business. The large importations from the Mediterranean have kept these descriptions at rates much below oats, with which they have been freely mixed; and as the stocks of English seem nearly exhausted, a good demand must yet be experienced—equal, we think, to any imports. So, with the prospect of beginning quite bare of this grain, good malting sorts seem again likely to be high priced. The best foreign, fit for distillation, is now worth about 30s. per qr.; while there are parcels of light grinding, say 48lbs. per bush., to be had at 22s. The

imports during the four weeks into London were 2,349 qrs. English, and 66,145 qrs. foreign, against 1,121 qrs. English, 51,415 qrs. foreign in May last year.

The only difference in malt during the four weeks has consisted in a reduction of 1s. to 2s. per qr. on secondary and inferior qualities, the best Ware still slowly selling at 69s.

Oats, notwithstanding their relative dearness and large foreign supplies, have given way but little in price, in consequence of short arrivals for five months previously; the granary stores produced by the gluts of last autumn and winter being very much reduced, and had they not fed the market, a very high range of prices must have been obtained, notwithstanding the low value of wheat. The first Monday, though only 19,465 qrs. foreign were up, was better supplied than since 7th Dec.; prices, therefore, though they had previously advanced, were fully maintained. The second Monday gave a total of about 61,000 qrs.; prices receded 6d. to 1s. per qr.; but dealers had so long been waiting to buy, that nearly the whole was cleared at this reduction, and the market has since been well furnished, the fourth market being rather against sellers; and at the week's end there was a further decline of 6d. per qr., in consequence of further large arrivals.

Ireland, in all parts of it, has been rapidly rising; and as we have frequently noted a less growth in that country, it seems improbable that this grain can be cheap this side of harvest, for the Russian supplies coming late will be an almost exclusive dependence. The imports into London during the four weeks have been 1,403 qrs. English, 3,380 qrs. Scotch, 16,435 qrs. Irish, and 139,623 qrs. from abroad, total 160,841 qrs., against 1,598 qrs. English, 761 qrs. Scotch, 9,740 qrs. Irish, 55,328 qrs. foreign in May last year.

Beans have been steady in value, a decline of 1s. on the first Monday being the only change that has occurred during the four weeks. Arrivals from Egypt have proved less than expected, and do not now threaten to be large. The imports have been in four weeks 1,963 qrs. English, 8,792 qrs. foreign, against 4,062 qrs. English, 936 qrs. foreign in the previous May.

With the exception of a liberal arrival of white peas from the Baltic on the second Monday, this pulse has become quite scarce, nearly the whole English growth appearing to be worked up; but the high rates that have been paying for duns and maples has caused a liberal use of cheaper substitutes, especially in low barley, so that their absence has been little felt. Boilers, too, being past their season, have not rallied in price, and the month in this respect has been without change. The imports of English into London were only 153 qrs., the foreign 3,575 qrs., against 407 qrs. English, 1,147 qrs. foreign in May, 1857.

In linseed there has again been a rise, to the extent of 5s. per qr. on the month's course, in consequence of the large export demand. This advance has contributed to increase the value of cake, which was previously declining in consequence of the rapid growth of the meadows and all vegetation.

The seed trade has been generally quiet, the low rates at which red cloverseed was forced off by factors and some holders having brought on a moderate speculation. American red has become worth 44s. to 45s. per cwt., and other kinds in proportion; white and trefoil have not attracted attention. Tares remaining scarce have sold in retail, at extravagant rates; and canary seed, from the same cause, has risen to five guineas per qr. Rapeseed, being badly spoken of abroad, has also risen; but it is thought the reports of injury have been exaggerated. White mustardseed remains dear, and brown quite neglected. Carraway, corianner, and hempseed much as last quoted, and only in retail demand.

RAPE CAKE, per ton .....£5 0s. to £5 10s.

HOP MARKET.

BOROUGH, MONDAY, May 24.—The trade during the past week has continued steady, and the market on the whole is very firm. Fine yearlings and good 1855's are in demand, and fully maintain previous rates. Our currency is as follows:—

Mid and East Kents....	70s. to 90s., choice 112s.
Weald of Kent.....	54s. to 60s., " 66s.
Sussex	50s. to 54s., " 60s.
Yearlings, &c.	21s. to 35s., " 50s.

WORCESTER, (Saturday last.)—The reports of the growing crop are still unfavourable; the flea continues its ravages, and the nights are too cold for the bine to grow out of their reach. The planters hold back their samples for higher rates, which the merchants are unable to give, causing a very quiet market.

MAIDSTONE, May 20.—Very little improvement has taken place in our hop grounds, and the College ground, although highly cultivated, is very backward. We are, generally speaking, short of bine, and full of flea, close to the bottom of the plant.—*Sussex Express.*

CHICORY.

LONDON, SATURDAY, May 22.—Although the supplies of Chicory are by no means extensive, the demand for that article has fallen off, and prices are with difficulty supported.

STRAW	24s. 28s.	25s. 28s.	24s. 28s.

COVENT GARDEN MARKET.

LONDON, SATURDAY, May 22.—Trade continues brisk, and the supply good. Some Cherries have been imported from France, but they are not very good. Strawberries are more abundant than they were last week. Some good Oranges have been imported from Barbary. Of Pears, Easter Beurré and Ne Plus Meuris may still be obtained. Barcelona Nuts fetch 20s. per bushel; new Brazils, 1s. 6d. do.; Spanish, 14s. do.; Almonds, 24s.; Walnuts, kilndried, 20s. do. Among Vegetables are Asparagus, Rhubarb, and Seakale. Winter Greens are plentiful. French salading is excellent; it still consists of Cabbage Lettuce, Barbe de Capucin, Batavian Endive, and Turnip Radishes. Cornish Broccoli realizes from 1d. to 2d. a head. French Beans are very plentiful. New Potatoes are largely supplied. Peas fetch 4s. per quart shelled; and green Artichokes from 4s. to 6s. per dozen. Cucumbers plentiful. Best samples of old Potatoes have advanced in price. Cut flowers chiefly consist of Orchids, Gardenias, Helictropes, Poinsettia pulcherrima, Geraniums, Violets, Mignonette, Heaths, Primulas, Camellias, Cyclamens, Tulips, Hyacinths, and Roses.

WOOL MARKETS.

ENGLISH WOOL MARKET.

LONDON, May 24.—There is a slight improvement in the demand for fine English wools, at fully last week's quotations, although several parcels are announced for public sale in London after the close of the colonial series. In prices, no quotable change has taken place. Low qualities of wool are a dull inquiry; nevertheless, holders generally are firm, and prices are well supported.

LEEDS (ENGLISH AND FOREIGN) WOOL MARKTE, MAY 21.—A fair demand, to supply immediate wants, for most kinds of English and combing wools, and prices are firm at late quotations. For colonial clothing wool the demand is not brisk, and the manufacturers in the district generally complain of the dulness of trade.

YORK WOOL MARKET, MAY 20.—To-day, the second market for the new clip of this year (the late rainy weather being unpropitious for sheep-shearing) we had but a small supply of wool, say about 10 or 15 sheets of new clip, and the same of old, with about half-a-dozen buyers. Several lots remain unsold, and the prices of those sold may be fairly quoted at from 10d. to 11d., and 12d. per lb., as per quality. One lot, in splendid condition, realized a price over those quotations, but the exact figure was not stated.—*Yorkshire Gazette.*

LIVERPOOL WOOL MARKET, MAY 22.

SCOTCH.—There is scarcely an average demand for Laid Highland Wool yet, and prices are somewhat irregular. White Highland is only in limited demand. There has been little doing in either Cheviot or crossed this week.

	s.	d.	s.	d.
Laid Highland Wool, per 24lbs.	10	0 to	11	0

FOREIGN.—The improved feeling evinced in the daily progress of the public sales in London, imparts confidence in the trade generally, and we have more doing by private contract at steady prices.

BRESLAU, May 20.—Since our last report business has been still flatter, and prices pursuing their downward tendency. Yet neither a further decrease nor the near approach of the new clipping could attract a greater number of purchasers. Manufacturers were persisting in their reserve, and speculators directing their attention to fresh wools. Transactions did not surpass the amount of 2,500 cwts., consisting chiefly of Russian wools, ordinarily washed and scoured, as well as of fine Silesian one-shear, skins in bundles, and slipes. The following prices have been obtained:—For Russian wools, ordinarily washed, at from 52 to 62 thalers; ditto, scoured, 80 to 86 thalers; fine Silesian fleeces, 87 to 91 thalers; fine locks, 62 to 65 thalers; Silesian slipes, 58 to 65 thalers per cwt. The chief purchasers were the Zollverein combers and clothiers, as well as home commissioners, who were acting for French and English account. More vivacity has been exhibited in transactions on the sheep's backs, and more than 3,000 cwts. of all descriptions have been in this manner contracted, at a reduction of 10 to 15 per cent. compared with last year's June fair quotations.—GUNSBURG, Wool-broker.

END OF VOLUME XLVIII.

Printed by Rogerson and Tuxford, 246, Strand, London, W.C.

FOR THE ENSUING GRASS HARVEST.

THE SALISBURY FIRST-PRIZE

AMERICAN EAGLE MOWING-MACHINE,

Winner of the Massachusetts Great Prize of Two Hundred Sovereigns,

OF THE

LARGE SILVER VASE,

OF THE

INDIANA STATE AGRICULTURAL SOCIETY,

FIRST PRIZE

OF THE

Royal Agricultural Improvement Society of Ireland,

AND COMMENDED BY THE

Highland and Agricultural Society of Scotland.

MESSRS. NOURSE MASON & Co., of Boston, Worcester, and Groton, Massachusetts, beg to announce the arrival in this country of their European Agent, with a limited number of these celebrated Mowing Machines, which are now ready for delivery. The superintendent of their mower factory accompanies them, to put them in order, and ensure their good performance of work. Messrs. N. M. & Co. request that such persons as sent orders to the agent having charge of the machine last season, which could not be executed) should make application to the undersigned as early as possible, to ensure the delivery of machines in season for the grass harvest. To the following brief extracts from the Report of the Judges of the Royal Agricultural Society, the *Times*, and the *Mark Lane Express*, we beg to call the attention of agriculturists:—

Journal of the Royal Agricultural Society—1857.

"Clayton's American Eagle Machine performed its work very satisfactorily; cutting low and clean, without at all distressing the horses by its required pace or draught; both were moderate, although it took a large average breadth.....We were gratified in coming to decided adjudication at once. We awarded the first prize of £15 to the Eagle machine, and £5 to Messrs. Dray and Co.'s (Catchcome) machine."

From the "Times"—July 23rd, 1857.

"The greatest novelty in this department, and one of the most meritorious and valuable pieces of machinery in the whole show, is the Eagle Reaper and Mower. In this machine we see just the simplicity of parts and consequent lightness, the small liability to derangement in working, and yet the greatest facility of accommodation to uneven surfaces of ground and irregular and tangled cropping which recommends it as emphatically a tool for the farmer."

From the "Mark Lane Express and Agricultural Journal"—Aug. 10, 1857.

"The 'Eagle' American reaper, invented by Mr. Caryl of Ohio, is the best we ever saw for mowing grass crops. ..... It is small, compact, and lighter than any good machine ever seen before, in proportion to the amount of work done, that is, having a five feet cut.....The draught is directly upon the axle of the main carriage-wheel, leaving the frame carrying the cutters free to conform to any uneveness of surface; and this frame is balanced, so that the driver can instantly raise the knives over an obstacle by depressing the back with his foot, yet the cutters may be only an inch above the ground. Instead of having spurwheels, pinions, and cranks to work the cutters, the main cast-iron travelling-wheel (of 3 feet 7 inches diameter and 11 inches broad) has a zig-zag curved slot through its periphery, the angles of which act as cams to give a vibratory motion to a roller connected with a cutter-bar. The knives are acute, not serrated, and slide above fixed sharp fingers, having thus a clipping or shearing action; they are kept close and free from clogging by a spring pressure-bar, and each individual knife may be unscrewed off and renewed at pleasure. The length of the vibration is only 2 inches, and the motion comparatively slow. When used as a mower, there is not a cog-wheel in the machine, and only 27 bolts."

Machines are now on exhibition at the works of Messrs. Ransomes and Sims, Ipswich; Richard Garrett and Sons, Leiston Works, Saxmundham; and in London. The price is £35, including reaping platform and fixtures complete. For circulars, and any other information, address,

H. S. OLCOTT, Sole Agent for EUROPE,

in care of Ransomes and Sims, Ipswich; 31, Essex-street, Strand, London; Richard Garrett and Sons, Saxmundham, Suffolk; and 40, Mark Lane, London.

ROBERT AND JOHN REEVES,
BRATTON, WESTBURY, WILTS,

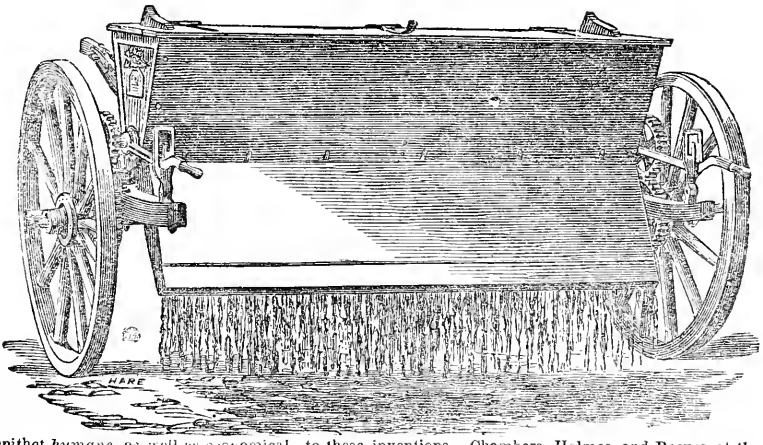
BEG to call attention to their useful Implement,

REEVES'S DRY MANURE DISTRIBUTOR,

which is equal to any for top drilling with all kinds of manure, and is superior to all others for putting in Soot.

PRICE.....£10.

THREE PRIZES were awarded to it last year—at the Bath and West of England Society, Newton; at the Royal Agricultural Society of England, Salisbury; at the Yorkshire Society, at York.



"The Dry Manure Distributors furnished one of the most interesting trials of the whole meeting. Who ever has witnessed the effect of hand-sowing guano on a dry windy March day will not refuse the epithet *humane*, as well as economical, to these inventions. Chambers, Holmes, and Reeves, at the descending scale of 20 gs., £14, and £10, are the names and the corresponding prices that offer themselves; that of Mr. Reeves, at the lowest sum, being introduced first to the Society at this meeting. The machinery of the two dearer ones is most ingenious, and almost inevitably exact in their steady delivery of the manure, whether damp or powdery. But Mr. Reeves' lower-priced implement is a positive boon to the *labourer* as well as the farmer."—*Report on Trial of Implements at Salisbury Meeting, by C. W. Hoskyns.*

CHANDLER'S PATENT LIQUID MANURE DRILL,

After the test of Ten years, is still acknowledged to be the most simple and efficient.

R. & J. REEVES have made arrangements with Mr. CHAMBERS to Manufacture his PATENT LIQUID DROP COULTER, so hat those who prefer the bunching system can now have the most complete Drill that has been yet offered to the public.

REEVES' PATENT ECONOMICAL DRILLS,

For Drilling all kinds of Artificial Manure with Roots or Grain, in their pure state, without the expensive system of mixing them with a large quantity of ashes. They will Drill from 2 to 20 Bushels per Acre, and will be found very useful when water is too scarce to use the Liquid Drill, and also on light down land. Prices from £8 to £14. They gained Two Prizes and a Silver Medal last year (being their first year).

REEVES' PATENT HAND DRILL,

For Gardeners, Market Gardeners, and small Occupiers, will Drill or Bunch Onions, Parsnips, Carrots, Peas, Beans, Wheat, or any other Grain; will drop Mangel Seed in Bunches at different distances, and will be found very useful for persons accustomed to thin seeding, as they will drop 2 or 3 corns (only) in Bunches at 6 inches apart.

Price List and particulars sent post free on application.

BRATTON IRON WORKS, March 27, 1858.

RANKIN'S
NEW PATENT CORN SCREEN AND SMUT MACHINE
MANUFACTURED SOLELY BY
R. & J. RANKIN, UNION FOUNDRY, LIVERPOOL.

THE very great improvements made in this new PATENT SMUT MACHINE comprise an arrangement by which (in addition to freeing and purifying the Wheat from *all Smut, however badly it may be affected*) all Sand, Seeds, and heavy matter are extracted in one operation. The Machine has a Double Action upon the Wheat, and combines all the important advantages of the original (Grimes') Machine, with the addition of those of a *Wire Screen*. The following Testimonials prove that the Machine is found to be the best of the kind in use:—

Messrs. R. & J. Rankin, Liverpool. [COPY.] Slane Mills, 14th August, 1856.

DEAR SIRS,—We have much pleasure in saying that the Patent Smut Machine has given us every satisfaction, and for so far has not cost us one penny. The working parts—that is, bearings, &c., are just as good as the first day we put it to work, now twelve months ago, and it has run nearly every working-day since.

Yours, truly,
(Signed) WETHERILL, POWELL, & Co.

Boston, 25th July, 1857.

GENTLEMEN,—Your Smut Machine I consider to be the best invented, and after working it seven years I find it to be as effective in its operations as it was the first week it was erected.

I shall be happy at any time to render an account of it and its good qualities when called upon; and I am, Gentlemen, your obedient servant,
(Signed) A. REYNOLDS (late Reynolds & Son).

Amersham, Bucks, November 8, 1855.

RANKIN'S NEW PATENT BONE MILLS.

These MILLS are adapted for the use of Farmers and Manufacturers, and are made in all sizes. They are a most decided improvement upon those in ordinary use, taking much less power to drive them, whilst they work far more efficiently. The Mills will Grind the largest and hardest Bones with ease to any degree of fineness that may be wished, there being provision made to regulate their working as may be required.

Manufacturers will find this Mill to be much more durable, to Grind quicker, and to a greater degree of fineness than any other.

TESTIMONIAL.

This is to certify that Messrs. Rankin, of Liverpool, have fixed one of their Four-horse Bone Mills for me, with which I am perfectly satisfied, not only as it regards the power taken to drive it, but also the fineness of the Bones when ground. The principle I consider superior in every respect to the old ones. The work is exceedingly well done, not only as it regards the Mill itself, but the Horse Gear is of a very superior character. I shall be happy to show the Mill when working, or answer any enquiries.

Messrs. R. & J. Rankin, Liverpool. (Signed) THOMAS H. MORTEN.

APPLY TO R. & J. RANKIN, SOLE MAKERS, UNION FOUNDRY, LIVERPOOL.

HAY-MAKING MACHINES, HORSE RAKES, &c., &c.

B. SAMUELSON'S IMPROVED DOUBLE-ACTION HAY-MAKING MACHINES possess the following advantages:—

NON-LIABILITY TO CHOKE.
INSTANTANEOUS REVERSING ACTION FOR TEDDING, and for REGULATING HEIGHT of FLYERS.
DURABILITY OF WEARING PARTS.
EXCEEDING LIGHT DRAUGHT.

Price.....£13 13s.

HORSE RAKES.

MARYCHURCH'S PATENT SELF-ACTING HORSE RAKE, which was awarded the First Prize and a Gold Medal at the Paris Exhibition.

Price, 7¼ feet extreme width .....£8 8 0 | Price, 8½ feet extreme width £9 0 0

B. SAMUELSON'S HORSE RAKES.

Price, 7½ feet extreme width .....£7 10 0 | Price, 8½ feet extreme width £8 0 0

HAND DRAG RAKES..... 12s. each.

The above prices include (with few exceptions) the Carriage to any Railway Station in England, Dublin, Cork, &c.

ALSO,

CLOD CRUSHERS, FIELD ROLLERS.
CARTWRIGHTS' PATENT CHAIN HARROWS, LIGHT AND HEAVY SEED HARROWS.

HUCKVALE'S PATENT TURNIP SINGLER AND HOE, HORSE HOES, 3 and 5 Tyne.
LAWN MOWING MACHINES, &c., &c.

ILLUSTRATED CATALOGUES descriptive of the above, and Mr. Samuelson's other Implements, will be forwarded post free on application to

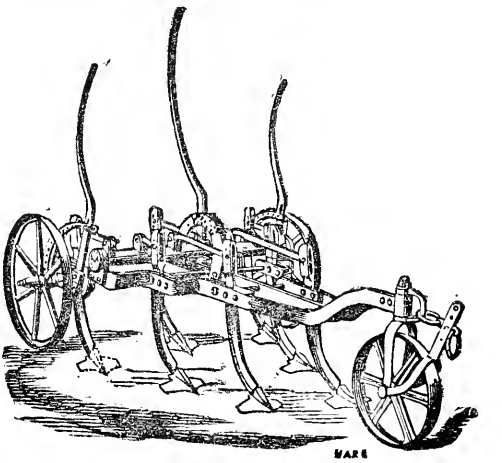
B. SAMUELSON, BRITANNIA WORKS, BANBURY, OXON.

COLEMAN'S PATENT PRIZE CULTIVATOR.

FOR Spring work this Implement is most effectual and economical, thoroughly breaking up and pulverizing the surface without turning it over, and at one-third the cost of ploughing.

Its strength, convenience of management, and ease of draught are unrivalled.

The Public are respectfully reminded that besides a large number of FIRST PRIZES given by the Royal and other principal Societies in the Kingdom, the Royal Agricultural Society of England, at their Triennial Competition, at Chelmsford, awarded Coleman's Cultivator TWO FIRST PRIZES, as the best Cultivator, and the ONLY FIRST PRIZE FOR PARING.



MANUFACTURED BY

COLEMAN & SONS, CHELMSFORD,

Of whom Prices and Testimonials may be obtained post free.

ALSO,

COLEMAN'S PATENT PRIZE EXPANDING HARROWS,

AND

COLEMAN'S IMPROVED HANSON'S PATENT PRIZE POTATO DIGGER,

Of which Implement COLEMAN & SONS are Sole Manufacturing Agents for England and Wales.

HOLMES AND SONS' IMPROVED PRIZE MANURE DISTRIBUTOR

WILL Distribute, in a most perfect manner, either broadcast or in rows, from Two to Twenty Bushels per acre of any description of Artificial Manure, whether in a moist or dry condition.

For the above Machines Messrs. HOLMES & SONS have received the following awards:—

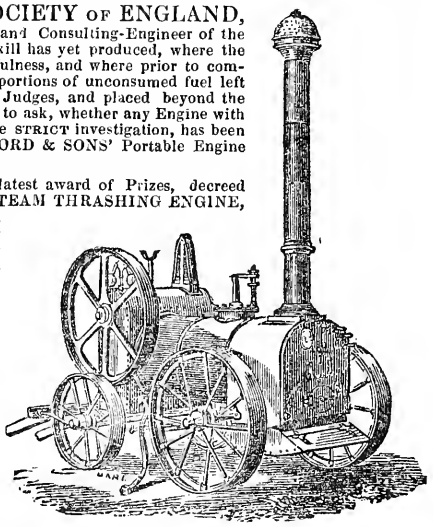
HOLMES AND SONS,

PROSPECT PLACE WORKS, NORWICH.

BATH AND WEST OF ENGLAND AGRICULTURAL SOCIETY—MEETING AT CARDIFF.

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S
FIRST PRIZE PORTABLE STEAM THRASHING ENGINE.



THE last trials of the ROYAL AGRICULTURAL SOCIETY OF ENGLAND, conducted under the most searching investigation of the Judges and Consulting-Engineer of the Society, aided by the most perfect testing apparatus that mechanical skill has yet produced, where the fuel for trial was weighed and watched by the Judges with extreme carefulness, and where prior to commencing the strict testing of consumption of fuel per horse-power, all portions of unconsumed fuel left from preliminary operations were taken back into the custody of the Judges, and placed beyond the possible reach of any party under trial, induce the successful competitors to ask, whether any Engine with *horizontal* cylinder, when in its very best condition, and under the same STRICT investigation, has been able to effect the same amount of duty as has been effected by TUXFORD & SONS' Portable Engine with *vertical* cylinder?

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND, at their latest award of Prizes, decreed the merit of the FIRST PRIZE to TUXFORD & SONS' PORTABLE STEAM THRASHING ENGINE, the Judges at the same time declaring, in addition to its other excellencies, that the STRAW SHAKER AND BARLEY-HORNING APPARATUS OF TUXFORD AND SONS' PATENT COMBINED THRASHING MACHINE were PERFECT in their operations.—(*Vide the Journal of R. A. Society*, Vol. xvi., page 614.)

The superiority of TUXFORD & SONS'

PATENT PORTABLE IRON-HOUSED STEAM THRASHING ENGINES,

with *upright* Cylinders and Improved Boilers, for continuance of power and economy in fuel, over Engines with *horizontal* Cylinders, is well known in all parts of England wherever they have been brought into competition with other Engines (the proportion of parts and arrangement of the Carlisle Prize Engine Boiler is strictly adhered to when a Tubular Boiler is selected in preference to a Combined Boiler); and their

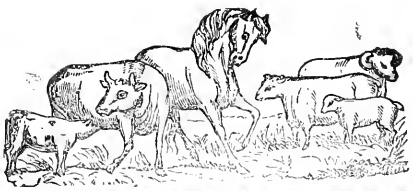
PATENT COMBINED THRASHING, SHAKING, AND DRESSING MACHINES,

for simplicity of construction, the amount of work performed, and perfection in the Thrashing, Shaking, and Dressing operations, have the well-merited reputation of standing at the head of their class.

Illustrated Catalogues, with Prices, forwarded free on application to the Manufacturers,

TUXFORD AND SONS,
ENGINEERS, BOSTON, LINCOLNSHIRE.

Patronized by the Principal Farmers and Graziers in the Kingdom.



CUFF'S FARMER'S FRIEND.

One dose of this invaluable medicine will cure the SCOUR or LOOSENESS in Lambs, Calves, Sheep, Colts, Heifers, Steers, and all Cattle, without leaving costiveness; and given occasionally to Beasts whilst fattening will promote a healthy and thriving condition. It will also perfectly cure the FRET, COLIC or GRIPES in Horses. Price 1s. 8d. or 3s. per Bottle.

CUFF'S FOOT-ROT POWDER

Is a cheap and effectual remedy for the FOOT-ROT or HALT, a single Packet of which will cure One Hundred Sheep, and large Flocks may be soon freed from the Disease by its use. It has been extensively used and highly approved of for nearly thirty years by large Sheep Breeders throughout the Kingdom. Price 1s. per Packet.

CUFF'S FLY, SCAB & MANGE OIL

Will very quickly destroy MAGGOTS in Sheep, and LICE or VERMIN in all animals. It will also cure the MANGE, and SKIN DISEASES in Horses or Cattle, and effectually cleanse a Flock of Sheep from the SCAB or SHAB. Price 1s. 8d. and 3s. per Bottle.

THE BRITISH SHEEP WASH

Is used for Dipping or Dressing Sheep and Lambs, without boiling, to prevent the Fly striking, and the Scab or Shab from spreading, and effectually to destroy TICKS, LICE, and VERMIN in Sheep. Price 2s. 9d., 5s., and 10s. per Jar; or 2s. 6d. per packet.

SHERWOOD'S ORIGINAL DRIFFIELD OILS

Are strongly and confidently recommended for preventing GANGRENE or MORTIFICATION after Lambing or Calving, and for Healing CUTS, STABS, WOUNDS, BRUISES, STRAINS, SWELLINGS, &c., &c.. As these Oils are in constant use by some of the most celebrated Breeders in the world, and have maintained a reputation about fifty years, it would be superfluous to enlarge upon their value and importance. Pints, 2s. 6d., Quarts, 5s.

Prepared by J. H. CUFF, No. 10, Smithfield Market, London, and sold by Druggists and Medicine Vendors

None is Genuine unless signed by J. H. CUFF in writing.

IMPORTANT TO FLOCKMASTERS.

THOMAS BIGG,

AGRICULTURAL AND VETERINARY CHEMIST,

BY APPOINTMENT, TO H.R.H. THE PRINCE CONSORT, K.G., &c.

LEICESTER HOUSE, GREAT DOVER-STREET, BOROUGH, LONDON,

Begs to call the attention of Farmers and Graziers to his valuable SHEEP-and LAMB DIPPING COMPOSITION, which requires no Boiling, and may be used with Warm or Cold Water, for effectually destroying the Tick Lice, and all other insects injurious to the Flock, preventing the alarming attacks of Fly and Shab, and cleansing and purifying the Skin, thereby greatly improving the Wool, both in quantity and quality, and highly contributing to the general health of the animal.

Prepared only by Thomas Bigg, Chemist, &c., at his Manufactory as above, and sold as follows, although any other quantity may be had, if required:—

4 lb. for	20 sheep,	price,	jar included	.....	£0 2 0
6 lb.	30 ,,	,,	,,	.....	0 3 0
8 lb.	40 ,,	,,	,,	.....	0 4 0
10 lb.	50 ,,	,,	,,	.....	0 5 0
20 lb.	100 ,,	,,	(cask and measure		0 10 0
30 lb.	150 ,,	,,	included)		0 15 0
40 lb.	200 ,,	,,	,,	.....	1 0 0
50 lb.	250 ,,	,,	,,	.....	1 3 6
60 lb.	300 ,,	,,	,,	.....	1 7 6
80 lb.	400 ,,	,,	,,	.....	1 17 6
100 lb.	500 ,,	,,	,,	.....	2 5 0

Should any Flockmaster prefer boiling the Composition, it will be equally effective.

He would also especially call attention to his SPECIFIC, or LOTION, for the SCAB, or SHAB, which will be found a certain remedy for eradicating that loathsome and ruinous disorder in Sheep, and which may be safely used in all climates, and at all seasons of the year, and to all descriptions of sheep, even ewes in lamb. Price **5**s. per gallon—sufficient on an average for thirty Sheep (according to the virulence of the disease); also in wine quart bottles, 1s. 3d. each.

IMPORTANT TESTIMONIAL.

"Scoulton, near Hingham, Norfolk, April 16th, 1855.

'Dear Sir,—In answer to yours of the 4th inst, which would have been replied to before this had I been at home, I have much pleasure in bearing testimony to the efficacy of your invaluable 'Specific for the cure of Scab in Sheep.' The 600 Sheep were all dressed in August last with 84 gallons of the '*Non-Poisonous* Specific,' that was so highly recommended at the Lincoln Show, and by their own dresser, the best attention being paid to the flock by my shepherd after dressing according to instructions left; but notwithstanding the Scab continued getting worse. In December I informed the 'Agent for the above Specific,' that the flock was not cured, and that it required their immediate attention. The Agent informed me they should be at once seen to, but did not do so until *five* weeks afterwards, and in the mean time the Scab spread over the whole flock, that I never saw such a disgraceful sight in my life; and when the Dresser was sent over to inspect the Flock, he decided on not dressing them again, as one-third of the Sheep had lost half their wool. I then agreed with an experienced dresser in Norfolk to dress the flock, and when he saw the sheep he declined doing them, as they were so very bad, and the time of lambing so near. Being determined to have the Scab cured if possible, I wrote to you for a supply of your Specific, which I received the following day; and although the weather was most severe in February during the dressing, your *Specific* proved itself an invaluable remedy, for in three weeks the Sheep were quite cured; and I am happy to say the young lambs are doing remarkably well at present. In conclusion, I believe it to be the safest and best remedy now in use.

"I remain, dear Sir, your obedient servant,

"For JOHN TINGEY, Esq.,

"To Mr. Thomas Bigg." "R. RENNY.

In addition to the foregoing, he has very materially improved, as well as considerably reduced the price of his Dipping Apparatus; and he would venture to suggest that no Flockmasters ought now to be without one. Price in London.

New and Improved Dipping Apparatus, on Wheels	£14	0 0
Ditto ditto with Iron-bar Drainer	5	0 0
Ditto ditto	4	0 0
Ditto, plain, with Wooden Drainer.....	3	0 0

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD: The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; Mann, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROFT, Bury St. Edmunds; DOVE, Swindon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

ELEGANT PERSONAL REQUISITES.

Under the Patronage of and Royal Family the several Sovereigns

Her Majesty "The Queen," of Great Britain, and Courts of Europe,

AND UNIVERSALLY PREFERRED.

ROWLANDS' MACASSAR OIL

Is universally in high repute for its successful results during the last half century in the GROWTH, RESTORATION, and IMPROVEMENT of

THE HUMAN HAIR.

It prevents Hair from falling off or turning grey, strengthens weak HAIR, cleanses it from Scurf and Dandriff, and makes it BEAUTIFULLY SOFT, CURLY, and GLOSSY.

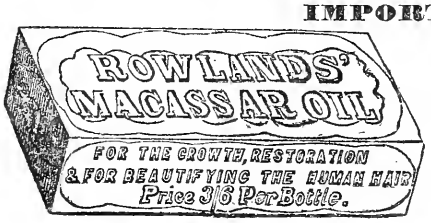
In the growth of

THE BEARD, WHISKERS, AND MUSTACHIOS

it is unfailing in its stimulative operation. For CHILDREN it is especially recommended as forming the basis of A BEAUTIFUL HEAD OF HAIR.

Price 3s. 6d.; 7s.: Family Bottles, equal to four small, 10s. 6d.; and double that size, 21s.

IMPORTANT CAUTION.



To prevent the substitution of *Spurious Imitations* for the genuine article by unprincipled shopkeepers, A. R. & Sons here add a small copy in *outline* of their Label (as it appears round the bottle) from the burin of Messrs. Perkins, Bacon & Petch, the eminent engravers, of London.

Another portion bears the Signature of the Proprietors, in Red Ink—

"A. ROWLAND AND SONS."

ROWLANDS' KALYDOR,

AN ORIENTAL BOTANICAL PREPARATION

FOR IMPROVING AND BEAUTIFYING THE COMPLEXION AND SKIN

It eradicates all REDNESS, TAN, PIMPLES, SPOTS, FRECKLES, and DISCOLORATIONS, and renders

THE SKIN SOFT, FAIR, and BLOOMING.

It obviates all the effects of Climate on the Skin, whether with reference to cold and inclemency, or intense solar heat, and affords immediate relief in cases of sunburn, stings of insects, or incidental inflammation. Gentlemen after shaving will appreciate its softening and ameliorating properties.—Price 4s. 6d. and 8s. 6d. per bottle.

CAUTION.—The words Rowlands' Kalydor are on the Wrapper, and their signature, "A. Rowland & Sons," in red ink, at foot.

A GOOD SET OF TEETH

Ever insures favourable impressions, while their preservation is of the utmost importance to every individual, both as regards the general health by the proper mastication of food, and the consequent possession of pure and sweet breath.

ROWLANDS' ODONTO,

OR, PEARL DENTIFRICE,

Compounded of the choicest and most recherché ingredients of the ORIENTAL HERBAL, and of inestimable value

PRESERVING AND BEAUTIFYING THE TEETH,

IMPARTING A PEARL-LIKE WHITENESS,

STRENGTHENING THE GUMS,

And in rendering

THE BREATH SWEET AND PURE.

CAUTION.—The words Rowlands' Odonto are on the Label, and A. Rowland & Sons, 20, Hatton Garden, on the Government Stamp affixed on each box.—Price 2s. 9d. per box.

Sold by A. ROWLAND & SONS, 20, Hatton Garden, London, and by Chemists and Perfumers.
